THE  
GARDEN

The title "THE GARDEN" is rendered in a highly decorative, calligraphic font. The word "THE" is in a smaller, blocky serif font above "GARDEN". The letters of "GARDEN" are large, ornate, and intertwined with delicate, light-colored floral and vine motifs. The background is a dark, textured surface, possibly leather or cloth, with a double-line border.

---

IN carrying out for THE GARDEN a Portrait Gallery of those Horticulturists who have given special proofs of their love and skill, whether in their work at home, in their exquisite specimens of superior culture shown at our exhibitions, or in the instructive results of their experience, communicated through the public press—who have most distinguished themselves in the great object of our brotherhood, namely in their endeavours to amplify all things pleasant to the eye and good for food, to reclaim and restore, to make the desert smile, we shall not find much delay or difficulty in resolving the question of precedence. We want to know who has given, so far as horticulture is concerned, the greatest happiness to the greatest number, and there is no need to appoint committees, or to send abroad commissioners, before we can attain our wish. We have not to seek our hero in “scientific” schools, we shall not find him poring over elongated Latin, over the herbarium, or the “hortus siccus;” our wreath of Laurel, with which we propose to crown him, is not mixed with Botany Bays; we shall not discover him even amid those distinguished men who have made one branch of our gentle art their peculiar study and success; we cannot give the Golden Apple to Venus, because we want something more than beauty; but we must bestow the Palm upon one who has achieved greatness, both in flowers and in fruits, who some forty years ago, found Love asleep among the Roses, roused him, trained him, made a pleasant, popular, man of him—who wrote the first descriptive catalogue of Roses ever published, and the first reliable guide for amateur Rosarians, an excellent manual, now in its tenth edition—who introduced the use of the Italian “Manetti” Rose as a stock on which to bud and graft the more lovely varieties from France, and an admirable nursing-mother it has proved, in many cases, where rough old Briareus has failed to rear a family—who subsequently invented Orchard Houses, and who has originated, and still originates, new varieties of our most luscious fruits. Yes; to THOMAS RIVERS we must give in our gallery the third welcome, the most conspicuous position, the most favourable light.

That light falls on just such a head as one would expect to see above the shoulders of a man who had lived long and laboured heartily among the most beautiful works of the Creator; it falls upon a handsome, thoughtful, kindly countenance. When he who writes was only an entered apprentice in one of the most distinguished lodges (“Rose Croix”) of Free and Accepted Gardeners, he would sometimes amuse himself with imaginary speculations as to the personal appearance of his worshipful master at Sawbridgeworth. There must be, he thought, a freshness, a frankness, a ruddiness, a benevolence, a gentle generous goodness, beaming in the face of one who has such a sympathy with sweetness and beauty. And when we met, pupil and master, this picturesque vision, instead of misconducting itself, as bright dreams will, was realised in broadcloth, and flesh and blood. As STANLEY walked up to the great explorer, and said “DR. LIVINGSTONE, I believe;” so could the student in Roses have addressed the professor, without an introduction, “MR. RIVERS, I’ve known you for years.”

With the place of honour, let us give him also the assurance of our affectionate respect. And, surely, there must be brightness for such a man, in the solemn nightfall of old age, to think how much pure innocent happiness he has diffused amid his fellows, by inducing them to love, and helping them to improve, their flowers and fruit-trees; surely it will sustain and cheer him in feeble or lonely hours to remember how many grateful friends he has, in whose enthusiastic spirit his own, rekindled, lives and glows again. For generations, when the bloom shall be upon the Peach, and the blush shall be upon the Rose, his memory shall live. The poet says:—

“You may break, you may ruin the vase, if you will,  
But the scent of the Roses will cling round it still.”

And we gardeners will say of our patriarch, though our “master be taken from our head to-day,” he shall survive in his books and in his works among us; and a likeness, truthful as that which we have before us in THE GARDEN to-day, shall be hung up in faithful hearts.

MR. RIVERS’S history is that of most men who have achieved success in their undertakings by constant and unremitting attention to their work. He was not born with a silver spoon in his mouth, and to this fact much of his success is probably due. He inherited a small property, and a business in which his enthusiastic love of plants enabled him to foresee a great development. When he began to turn his attention to his profession, Rose

cultivation was in a very different position to what it is at present. Standard Roses being principally imported from France, and in small quantities, he determined to visit France and examine the French mode of Rose culture for himself. The success of his earliest literary effort, "The Rose Amateur's Guide," established him at once as an English cultivator fully equal to the French in love of the flower and in skill in its cultivation. The book, in manuscript, was submitted by him to one of his earliest Rose friends, Professor JONES, of Haileybury College, then one of the most profound scholars of the day. Dr. JONES's approval was at once accorded, and "The Rose Amateur's Guide" was received by the public as it was received by Dr. JONES. While pursuing his Rose researches, the pyramidal mode of fruit-tree training, as universally practised in French and Belgian gardens, attracted his attention—always keen on matters likely to prove of general utility—and the "Miniature Fruit Garden," modest and small in its infancy, inaugurated a new era of fruit cultivation in English gardens. Although for years practised in France and Belgium, pyramidal fruit tree training does not appear to have been much employed in England until MR. RIVERS drew public attention to the extraordinary facilities given by this mode of culture. The frequent failure of the fruit crops led him to devise some simple and effective means of protecting fruit, and he lit upon the system of growing trees in pots. By very small degrees, and with constant experiments, extending over some years before finally giving the culture a name, he perfected the "Orchard House." Like the "Rose Amateur's Guide," and the "Miniature Fruit Garden," the "Orchard House" began at the beginning. During the time occupied in developing his ideas on these heads he was constantly occupied in studying and forming large collections of fruits, and nearly every continental new fruit found its way to Sawbridgeworth, and most of them eventually to the fire heap. MR. RIVERS was at one time a most ardent cultivator of what are called ornamental trees and herbaceous plants; his collections of both were at one time very large, and he was quite as enthusiastic a lover of these as of Roses. Loudon gave him the benefit of his vast knowledge, and took great interest in his various collections; in one tribe, that of the Oaks, his collection was unusually extensive. He has made good use of the "Orchard House" to endeavour to improve the varieties of Peaches. The few sorts selected as worthy of naming have been taken from more than 1,500 seedlings, and it may give some idea of the work done when it stated that these were all grown under glass. MR. RIVERS has been a large employer of labour; a small agricultural village has by the continued employment of the capital required in carrying out his ideas—all of which necessitate labour—been benefited by the large sums annually spent.

MR. RIVERS, through failing health, has retired from active life, yet his mind is still active. Seventy-six years is a long measure of life for a man, but few men can look back with greater satisfaction than he can on a life worthily spent and deserving in every way of the commendation that, as far as lay in his power, he has been a good citizen of a great country.

## THE GARDEN.

—o—o—o—  
 "This is an art  
 Which does mend nature: change it rather: but  
 THE ART ITSELF IS NATURE."—*Shakespeare.*  
 —o—o—o—

### CALIFORNIAN LILIES.

WE have just received, along with a parcel of Californian bulbs, the following observations on their culture and habits, from Dr. Kellogg, the well-known botanist of San Francisco, who has studied Californian plants thoroughly, not only in his cabinet, as many botanists do, but on the mountains and plains for months at a time. The subject is important to us at the present moment, when we are receiving fine Lilies in such quantities from California, not to speak of the many other beautiful bulbs that come from that favoured region.

Let us, in the first place, says Dr. Kellogg, "consider the Lilies how they grow." In a climate like that of California, distinguished by a wet and long dry season, we find these bulbs located say about 6 to 10 inches deep, and the fibres or roots shooting downwards 10 inches to a foot below that point, in search of food and moisture. Is it not evident, then, that such bulbs require a flower-pot at least 18 inches deep? Hence, ordinary pots must be utterly useless, or worse—cramping or inadequate to meet even primary natural conditions. Let any one take an improvised 5-gallon tin can, or the like, which is good enough, not to say the best; paint it rudely inside and out to preserve it; punch say at least three large holes in the bottom of it; plant, as in nature, in any good compost, and set your can, keg, or crock, as the case may be, in a shallow pan of water. You will soon have the pleasure of seeing a stout stem, of the thickness of your thumb, rising up and flowering gorgeously. If a plant spends its vital force in vain, searching for food or moisture, little or nothing else can be accomplished. *Abronia arenaria*, as the specific name indicates, grows in sand. If found on deep sand-drifts of the bay shore of San Francisco, or inland, it shoots down a stout fusiform root of indefinite length, but often poor and puny is the top, that creeps not far from the crown, with perhaps few flowers and little fruit. But mulch a moist, brackish, crackly soil, with only 6 or 8 inches of sand, and it will go down to, or a little into it, spread abroad its forked subdivisions and fibres, almost or quite horizontally; the crown-sprouts now run riotously, mantling the sand with vines, full of pink flowers in fruitful umbels unnumbered. Cultivators are apt to complain that many of their bulbs ere they bloom lose one essential beauty of plants, viz., their radicle leaves, which, they say, "dry up, and leave the stems looking naked and bare." Bulbs are frequently found upon exposed hills and slopes, rocks, &c., descending down dry and very hot valleys into debris and alluvial bottoms, where sand or loam with underground moisture abounds. The very same plants are seen to rejoice best where they find some shade and shelter, otherwise they bespeak a struggle for existence, *i.e.*, their leaves prematurely or naturally dry up early to save exhaustion. In half shade, along high banks and slopes, contiguous to creeks, with adequate subsoil moisture, we see *Cyclobothra alba*, with long and beautiful glaucous leaves, say an inch and a half wide, 18 inches to 2 feet in length, accompanying the flowers, ten to twenty in number; the golden *C. pulchella* and most others tolerate more sun and drought, with their companions the *manzanita* (*Arctostaphylos glauca*) Oaks, &c., near whose shades it is wont to linger; but its best forms love rich, rocky, half shady drains, leaf and flower being companions to the close. Witness *Senbertia laxa*, 2 to 4 feet high, and the *Dichelostemas* and *Brodias*, with from ten to fifty flowers, and green leaves in similar grace and completeness and beauty. The list might be extended; but what we desire to say and impress on our readers is, that the same plants exposed are barely one-quarter as large as these, and have no green leaves at all, or at best, a poor apology for them, and so of numberless others.

What lesson do such facts teach? Surely that the cultivator should imitate Nature in her best aspects, and it is by

no means difficult to exceed even her highest standard. Bulbous plants form no exceptions. It would, indeed, be folly to fold one's hands at the very first failure; and with what delight do we behold one joyously filling up the full measure of its glory! In the loose soils in which we usually place our bulbs are they as well situated as in their native matrix? The soil then must needs be packed firmly and uniformly. It is the life-struggles with difficulties that bring out the best qualities of the man—the fruits and flowers, roots and bulbs, born of the great mother. Resistance above reacts below, gives spread, depth and vigour in the direction of least resistance. The root—the strong foundation—is of first consideration in all structural building, and should be well laid, cherished, and preserved. We do not say it should be founded upon some suitable rock, but we sometimes think so; radiated heat and graduated temperature, sweetness of drainage, and it would seem reasonable that in due time some resistance from below, also, are all requisites of high culture. May not the cultivator in his undue solicitude, be also to blame, and by some shortcoming fail, or from excess undo by overdoing? Suppose he flood too continuously between loose scales, adding excessive heat withal, ought not he to expect just the result urged? Now, we seldom see in nature bulbs sheltered by shrubs, rocks, logs, bark, leaves, &c., or in very compact soils rotten at the tips of the scales, and hence a lure to maggots and grubs; nor often in such sandy and gravelly soils as readily absorb, drain, and disperse any excess of top moisture. We appeal to the observations of careful collectors. Let us then copy the best conditions, and we feel assured the result will confirm our rather hasty hints.

In conclusion, we dare not presume that even a title of what we ought to say has been noted; in short, we have confined ourselves only to what may be considered peculiar to climatic conditions. Erudite and complex recipes relative to proper mixtures of soils, and common management may well be left to the knowledge and judgment of those who believe in them. With such a wealth of sunlight and heat above as falls to the lot of California, and no lack of the necessary medium moisture below, I see no reason why we may not allow Nature, under human hands, to grow her fragrant white *Lady Washington Lily* 6 or 7 feet high, with ten to thirty or more flowers, just as we see it wild. *L. Bloomerianum*, too, is a perfect giant among Lilies, when at its best making a right super-royal display. Even our little orange *L. parvum*, I found at the Sierra summit over 5 feet high, and bearing fifty flowers—carefully counted, but the plant was sheltered and shaded by an old emigrant water-tank stilted up, now dry and long ago abandoned, but its roots found a fair supply of water from beneath.

### NOTES OF THE WEEK.

— THE double white *Pink Flower* of Eden now coming into flower in warm greenhouses is a remarkably valuable plant. It opens at first somewhat greenish, but soon unfolds into a large and beautiful double flower. Mr. Andrew Henderson considers it more valuable for cutting than any of the Carnations, and it flowers profusely.

— WE are glad to learn that Messrs. Stansfield, of Todmorden, have at last succeeded in so cultivating that marvellously attractive *Moss*, *Schistostegia pennata*, that they are now enabled to supply it in miniature grottoes made of cork bark, so that it may be grown in any greenhouse, or even in the drawing-room. If the plant succeed thus, we shall have to thank Messrs. Stansfield for one of the most charming features ever added to the indoor garden or the garden in the house. Hitherto in cultivation we have only seen the plant at Messrs. Stansfield's and at Messrs. Baekhouse's; the object has long been to so increase and transport the plant that it may be established in other gardens.

— WE understand that the nursery and seed business of Messrs. Lawson & Son, both in Edinburgh and in London, is henceforth to be carried on as a joint-stock company, under the name of "The Lawson Seed and Nursery Company (Limited)." This old and universally-known business has now been carried on for over a century, the originator of it, Mr. Peter Lawson, having died in 1820 at a hale old age; since then Mr. Charles Lawson, of Borthwick Hall, has carried on the business as the respected head of the firm. We believe that nearly all the available shares were taken up within a few days of the intimation of the proposed change being sent out to the firm's customers, and that the company is likely to be a

strong one, both in regard to supporters in trade and capital. A feature worth noticing is that a few of the most valued *employés* of the old firm, who will hold shares to a considerable amount in the new one, will be associated with the general manager in the carrying on of the company's business, thereby giving a certain guarantee that nothing will be wanting in the management to maintain the prestige of the name, as well as the good opinion of customers and the interests of the shareholders. Mr. Syme is to be general manager, and Mr. Mitchell (late gardener at Hamilton Palace) is to have the charge of the Nursery department.

— WE learn that a sale of Easter Beurré Pears sent from California has recently taken place in Glasgow.

— THE new and remarkable *Iris iberica* seems to be hardy about London, at least there is now a bed of it in the open air in the Wellington Nurseries in perfect health.

— THE first flower of the new year that we notice opening about London is the modest-looking *Helleborus purpurascens*, not a showy species by any means, but worthy of a place where full collections of hardy plants are grown.

— WE are glad to include Buckingham among the towns which are awaking to the importance of tree-embellishment. Recently a number of trees have been planted there at the expense of Mr. Egerton Hubbard.

— AT the suggestion of Mr. Carruthers, the time of competition for Lord Cathcart's prize for the best essay on the cause of, and mode of preventing, the Potato disease, has been extended to November 1st, to give candidates an opportunity for practical research on the subject.

— MR. LYNCH WHITE, so well known to gardeners as a horticultural engineer, has, as will be seen by an advertisement in another page, retired from business, which henceforth is to be carried on by Mr. Lynch White, jun., Mr. Baker, and Mr. Dunbar, under the name of the Thames Bank Iron Company.

— PEACHES were very freely discussed at the December meeting of the Potomac fruit growers, and great importance was placed on earliness. John Saul read extracts from English papers showing that the early Beatrice is taking a decided lead. A gentleman from North Carolina said he had a quantity of this variety fully ripe on the 15th of June of the present year (this date being two weeks ahead of Hale's early).

— *Le Cultivateur*, a French journal, says it has been discovered that on a tree trained as an espalier, the Pears which rested on a branch grew more rapidly and much larger than those wholly self-supporting. The explanation, which was confirmed by direct experiments, is that when the stems were relieved from the compression caused by the weight of the Pears, the sap found uninterrupted flow, and was furnished in correspondingly greater supply.

— IMPROVEMENTS continue here and there to be made in Hyde Park. On Wednesday, that portion of the ride in Rotten Row, extending from Hyde Park corner to Albert Gate, which has for the last two months been closed for repairs, was opened to equestrians. The foundation of the track has been examined, repaired, and the entire length covered with bright red sand and gravel. The length from Albert Gate to Kensington Gardens is now also, by order of the Commissioners of Works and Public Buildings, being subjected to a similar process.

— THE following American ways of preserving Spinach against very severe frost may not be without interest to our readers:—The first and least expensive practice is to cover the bed at once with a coating of an inch in thickness of salt, hay, or straw. This will protect the leaves from frost, and by removing the mulch the Spinach will be found in good condition. The second method is, to cut off the Spinach before the ground becomes frozen, leaving, if possible, a little earth attached to the roots. This cut Spinach is then placed in a cold frame in a layer eight or ten thick, with some leaves from the woods spread on top. The sashes are kept on the frame, and the Spinach will keep green until wanted.

— THE Royal Horticultural Society has, as we have already announced, decided to hold its provincial show for 1873 at Bath, and a very charming site has been selected. An influential meeting of local residents was recently held at the Guildhall of that city, which had been convened by the Mayor, who also took the chair, and briefly reviewed the history of the recent provincial meetings of the society. Mr. S. Butler, of Combe Hay, then read a report, which, *inter alia*, stated that a guarantee fund of £365 (a sum considerably in excess of the amount required by the Royal Horticultural Society) had been raised; that satisfactory arrangements had been made as to the use of the site selected for the exhibition; that £349 15s. had been raised towards the special prize fund—further contributions to which were urgently solicited; and that an influ-

ential local committee had been selected, with the Lord-Lieutenant of Somerset as president. The committee consists of 106 members; and Mr. J. Ostler, of 14, Bladud Buildings, Bath, was appointed secretary.

— THE pretty little *Cyclamen Peakeanum* is now, and has been for some time in flower in a warm greenhouse, of which it is one of the neatest ornaments. It differs from other kinds in being deliciously fragrant, in being evergreen, and in flowering continuously.

— WE noticed a nice batch of double *Cyclamens* coming into bloom in the Wellington Nurseries the other day, and doubtless we shall soon have quite a race of them. Double or semi-double *Cyclamens* are, however, anything but improvements on the single forms.

— WE understand that the large supplies of *Ipecacuanha* plants which have been so successfully sent to India of late were propagated and safely transmitted there by Messrs. Peter Lawson, of Edinburgh. It grows in their nurseries at Edinburgh quite freely, and may be seen there now by the hundred ready for shipment.

— WHAT is to become of the kitchen gardens of Versailles? Gardeners are actively at work in them, making hot-beds, plantations, and sowing, &c., of course with the intention of reaping produce of different kinds. For what reason, and above all, for whom?

— SOME varieties of Peas, though excellent in England, do not necessarily do well in America. "But last season," writes Mr. Mehan, editor of "The Gardener's Monthly," "we had an opportunity of examining a few of the new varieties raised by Mr. Laxton growing in this country, and we are now able to say that they proved excellent in every respect."

— THE next election of the Gardeners' Benevolent Institution will take place at the annual meeting, Jan. 21. There are nine candidates, in addition to Mary Young, whom the committee will recommend to be placed on the pension list without the trouble of an election.

— WE have just received from Mr. Scaling, the celebrated Willow grower of Basford, Notts, and author of "The Salix," some twigs of the interesting *Salix violacea*, gathered on the first day of the year, and furnished with numerous silvery and silky buds, which contrast prettily with the deep violet-brown coloured slender branches on which they grow.

— THE IMPERIAL CAULIFLOWER, according to the French *Revue Horticole*, is a new variety of much merit. Its excellence, however, consists in its earliness, the heads having been fit for use one season eighteen days, and the succeeding one thirty-two days before the Lenormand, cultivated under the same conditions. It is a variety of French origin.

— SOME valuable plants and seeds received by Messrs. Backhouse, from their collectors in North West America and California, are, we understand, to be sold on the 9th inst., at Stevens'. Among them are the new Dogstooth Violet (*Erythronium giganteum*); a Californian Lily, said to grow from 6 to 10 feet high, and to bear numerous large, fragrant flowers; *Lilium Washingtonianum*, *Cyclobothra pulchella*, various species of *Calochortus*, the "Vegetable Fire Cracker or Scarlet Wand" (*Brodiaea coccinea*), and other bulbs; also seeds of a new hardy Silver Fir, from the Rocky Mountains, thought by Dr. Englemann to be his "*Abies (Picea) concolor*," and of other choice Coniferae.

— THE sugar planters of Louisiana have been in very ill luck ever since the war. Despite brave struggles to reinstate this great industry in its former position, unpropitious seasons have kept down the yield. It is very doubtful whether such a series of bad crop years as those since 1864 has ever been experienced, and now we hear that a recent killing freeze will cause a loss estimated by some authorities at 50,000 hogsheds. Many planters, says the *New Orleans Picayune*, are wholly disheartened already, and if the worst reports now coming to hand prove correct, it is not improbable that many may abandon the culture of this staple and turn their attention to some more certain product.

— FEW can recollect such a "green yule" as we have had this year. In the garden at Bitton Vicarage, Gloucestershire, Mr. Ellacombe noted the following plants in flower on Christmas-day; many of them quite abnormal in their time of flowering, having mistaken Christmas for May:—*Rhododendron atrovirens*, *Tussilago fragrans*, *Sisyrinchium californicum*, *Daphne Fioniana*, red Primrose, *Garrya elliptica*, Ivy, Groundsel, Strawberry, *Chrysanthemum*, Czar Violet, *Iberis semperflorens*, *Tenacium fruticosum*, *Clematis cirrhosa*, *Arabis rosea*, Rose Aimée Vibert, R. Souvenir de Malmaison, R. Gloire de Dijon, R. Jules Margottin, *Arbutus Croonii*, *Helleborus niger*, *H. n. maximus*, *H. olympicus*, *H. orientalis*, *H. atrovirens*, *Cyclamen coum*, *Schizostylis coccinea*, *Maurandia Barclayana*, *Cheiranthus pulchellus*, *Jasminum nudiflorum*, and *Potentilla alba*.

## THE ARBORETUM.

## HARDY TREES AND SHRUBS.

BY GEORGE GORDON, A.L.S.

THE SPANISH MAPLE (*ACER GRANATENSE*).

THIS species forms a dense, round-headed deciduous tree, from 20 to 30 feet high, with spreading branches thickly furnished with slender, glossy chestnut-brown twigs, in alternate opposite pairs, and which, when leafless, are covered with small, pointed, downy buds. It is a native of Spain, in the valleys of the Sierra Nevada Mountains in Granada, at an elevation of from 5,000 to 6,000 feet, and was first introduced in 1838. The leaves are three and five lobed, leathery in texture, deep glossy green above, pale beneath, slightly heart-shaped at the base, on long, slender footstalks, and, with the exception of a little tomentum at the base of the palmate veins, on the under

A. granatense.

side, quite smooth on both surfaces. The lobes are acute pointed, with the three outer ones large, equal in size, and furnished with a few blunt serratures on the edges. The flowers are in nodding, many-flowered corymbs, greenish yellow, and produced in May. The fruit or keys are small and quite smooth, with thick carpels and parallel wings, somewhat distant apart. The Spanish Maple frequently produces fresh shoots after Midsummer, at the ends of the principal branches, furnished with small leaves, seldom exceeding an inch in length or breadth, and on very short footstalks, and in consequence of which it is sometimes named *Acer parvifolium*, or the small-leaved Maple. The only full-sized trees of this scarce Maple near London, or, perhaps, in England, are in the Victoria Park; but it is to be regretted that they are there placed in the interior of the plantations, and completely hidden. The length of a full-sized leaf is 5 inches, including the footstalk, which is 2½ inches long, and the breadth is 3½ inches.

## WILD PLANTS A GUIDE TO SOILS.

THE common Heath (*Calluna vulgaris*) grows naturally on most of the barren land that is suitable for tree planting. When it is rank and strong-growing, it indicates deep, black, mossy soil—poor and naturally unfertile, but which, if dry, and the altitude not too great, will grow Scotch Fir and Birch; if wet, Scotch Fir, Spruce, and Alder; but even for the last, it must be drained previous to planting. If the Heath is close and healthy, and mixed with Club Moss (*Lycopodium clavatum*), Tormentil (*Potentilla Tormentilla*), and some of the common Grasses, the soil is more fertile and suitable for Scotch Fir, Larch, and Birch. Some very healthy and thriving Larch and Scotch Fir plantations are growing on soil where these plants luxuriate. Ash, Beech, Elm, Oak, and Plane will grow there for ornament, but not for profit. The Cowberry or Cranberry of the Highlands (*Vaccinium vitis idæa*) is generally associated with the common Heath and Soft Grass (*Holcus lanatus*). It indicates a light sandy or gravelly soil, generally very hard and retentive; grows Larch and Scotch Fir, but they sometimes become affected with ground rot when from fifty to sixty years old. Birch and Mountain Ash thrive admirably upon it, but are not profitable. The Bilberry (*Vaccinium Myrtillus*) is generally found growing with the common Heath, and the Hard Fern (*Blechnum boreale*), Tormentil, &c. It indicates a superior class of soil for Scotch Fir, Larch, and Silver Fir, but especially the first—a heavy crop of which is almost invariably found on soils where the Bilberry is plentiful. If the situation is on a sloping hill or side of a ravine, the Norway Spruce, Ash, Beech, and Elm will succeed admirably on the level ground, or in the bottom of the ravine. The common Juniper (*Juniperus communis*), accompanied by the Bracken (*Pteris aquilina*), is very common in the districts where the Scotch Fir may be said to have its native habitat: indeed, in some Scotch Fir woods it grows as rank and profuse as the Furze, and makes excellent undercover. The soil is generally good for growing Pines where the Juniper grows, but occasionally varies in depth. The trees named as suitable for growing on the Bilberry land will grow with the Juniper; but we would prefer, for a profitable crop, to keep to the Scotch Fir, Larch, and Birch, giving the preference to the first, which almost invariably produces a heavy crop, and good quality of timber, on Juniper ground.

The common Whin or Furze (*Ulex europæus*) is very abundant on waste land, and seems to be such a selfish plant (if I may use the term), that other plants are rarely growing with it; but in close proximity, on good soils, are to be found Ragwort (*Senecio Jacobæa*), Thistles (*Carduus*), wild Clover (*Trifolium*), &c.; and on the poorer soils, Crowberry (*Empetrum nigrum*), Sorrel (*Rumex acetosella*), Carices, &c. The Ragwort and Thistles must be understood as applying to uncultivated ground; for if the ground has been cultivated, these are only a criterion as to fertility, and not to depth or quality of soil. The Furze, at a casual glance, is not a safe criterion as to the quality and kind of soil, as it will grow almost anywhere. Before fixing the quality of the soil, it is necessary that the quality and size of the Furze should be considered; as it is only on good loamy soil that it develops strong stems and branches. When it is found growing thus, the ordinary hard woods may be planted, along with Spruce and Silver Fir. If the situation is sloping or the sides of a glen, Larches will succeed; but they seldom attain a large size among Whins on flat ground. When the Whin is dwarf in habit, and the stems slender, it indicates thin gravelly soil, with a hard bottom, unfavourable for growing any kind of forest trees—Birch, Scotch Fir, and even Larch will grow if they can get a start; but the Whins are so aggressive that it is only by careful treatment that the trees are enabled to overtop them. However, when they do so, success is gained, as the Whins offer no further opposition. Although we have said that slender and dwarfish Whins indicate poor soils, there are exceptions, as in the case of Whins that have been burned or cut over; or, again, on ground that has been reclaimed, and afterwards allowed to return to its natural state. Under any of these circumstances, the Whin is slender and dwarfish for a short time. Taking the Whin alone, it is not a plant on which much dependence can be placed as a criterion of the quality of the soil; but when viewed with the plants growing in its immediate proximity, I consider it affords a sufficient indication of the soil above mentioned. The common Broom (*Cytisus scoparius*) is invariably found on dry situations, and always indicates a fair soil. If it is strong and healthy, and growing along with the Yarrow (*Achillea Millefolium*), Bird's-foot Trefoil (*Lotus corniculatus*), wild Clover, Tormentil, &c., the soil and subsoil are invariably good for planting trees. The kinds most suitable, if the situation is moderately sheltered, are Beech, Oak, Norway Maple, Plane, Larch, Silver and Scotch Firs; but if the situation is exposed, the Larch and Scotch Fir produce the most valuable crops. The Bramble (*Rubus fruticosus*) and Dog Rose (*Rosa canina*) indicate a good loamy soil, generally inclining to

clay, very suitable for growing ordinary hard woods, as also the Austrian Pine and Silver Fir. Although the Bramble and Dog Rose are always found growing on dry portions of soil, still ground in close proximity and the subsoil are often wet, and require to be drained before planting. The Raspberry (*Rubus Idaeus*) is often found on soils similar to the last, and denotes similar results; but it is also found on higher, more exposed, and poorer soils than suits either of the two last. When found thus, its stems are slender and short, and the leaves small, indicating a light soil suitable for Scotch Fir, Larch, Beech, Birch, and Mountain Ash. The bog Myrtle or sweet Willow (*Myrica Gale*) is common in some districts, often accompanied by the cross-leaved Heath (*Erica tetralix*), but invariably grows on a poor, wet, sandy soil, unsuited for trees; but, if thoroughly dried, will grow some of the hardy species, as Birch, Alder, Mountain Ash, and Scotch Fir.

The foregoing are some of our most common native shrubs; but there are some other species of flowering plants that are as much to be depended upon, as indicators of soils, as these are, and sometimes the flowerless plants are more reliable than others. The Male Fern (*Lastrea Filix-mas*) and the Bracken are not safe criterions as to the depth of the soil, but they can always be depended upon as to quality, for neither of them grow on bad soil. It is invariably good soil when they are accompanied by the common Bugle (*Ajuga reptans*) and the Primrose (*Primula vulgaris*), which are generally found in low-lying situations, or hollows, where an amount of soil has accumulated; and it may be asserted, that in this variety of soil almost any forest trees will succeed. But we particularly recommend, for the sheltered portions, the Silver Fir, Douglas Fir, Larch, Pinus Laricio, Elm, Ash, Plane, and Chestnut; and, for the more exposed parts, Larch, Scotch Fir, Beech, Norway Maple, Plane, Oak, and Birch. The appearance of the Foxglove (*Digitalis purpurea*) among common Ferns indicates a medium soil, inclined to be dry, but on which a great variety of trees will grow, and which I consider particularly suited for Beech and Scotch Fir. If the common Ferns are mixed with the Polypody (*Polypodium vulgare*), St. John's wort (*Hypericum*), &c., along with a sprinkling of Heath, the soil is generally more shallow, and contains large stones or boulders. Still, although shallow, it is always kindly, and will grow forest trees better than its appearance would indicate; but the Larch, Scotch Fir, Birch, Mountain Ash, and Hazel, are the varieties that thrive best on this soil. The Inland Bent (*Juncus squarrosus*) and the small Sedges (*Carex*) are generally found growing along with short Heath, and indicate a poor soil, with a retentive and impervious subsoil, invariably inclining to be wet, and in its natural state only suited for growing some of the common Willows, dwarf Birch, and Alder; but if drained, it will grow Spruce, and even Scotch Fir. In recommending Spruce, I am supposing that the situation is moderately sheltered, as these plants are often found at altitudes and in exposures quite unsuited for the growth of Spruce. Even the Alder, Birch, and Scotch Fir are seldom profitable trees on soils where the aforesaid plants are abundant. The Sheep Fescue (*Festuca ovina*) and the Wire Grass (*Nardus stricta*) are often found growing together, and, to the casual observer, may be taken for the same plant. They form the principal vegetation of some upland districts, and denote a dry, thin soil, comparatively rich in vegetable matter, but not very suitable for the growth of trees. The kinds most suitable are the Birch and Mountain Ash. The difficulty in growing trees on soils where these grasses predominate is more owing to the situation and the herbage than to the soil, as to all appearance the latter is generally good; but the situation, being so much exposed, is dried up in the summer season, and, during the winter, the herbage is so close that the moisture does not penetrate it readily. But when trees can be got to cover the ground where this herbage grows, their success is secured. The Tufted-hair Grass (*Aira caespitosa*) is generally found on light or sandy loam (usually poor), resting upon bluish clay, or sometimes running sand. The soil naturally is too wet for growing trees, but when drained is suitable for Ash, Elm, Poplars, Willows, and Spruce. The soil on which this grass grows varies, but still admits of the profitable cultivation of any of the trees before recommended.

The Broad-leaved Flag (*Iris Pseud-acorus*) is invariably found in hollows or flat ground, and indicates a brown, loamy soil, chiefly composed of vegetable matter. The situation is generally wet, but when drained is very suitable for growing tree Willows, grey, white, and black Poplars, Lime, Horse-chestnut, Ash, Elm, Spruce, &c. Where the Iris is close growing and abundant, it is sometimes difficult to get young trees to start, without deep trenching or pitting of the ground before planting, the former being preferable. The common Rush (*Juncus effusus*) is not particular as to soil, if the situation is sheltered and damp. The variety of soil is indicated by its habit. If robust, the soil is similar to that of the Iris, and will grow the same kind of trees; but if slender, the soil is poor, and principally com-

posed of sand or a light loam, most suitable for growing Alder and Spruce. Rushes afford an unmistakable proof of dampness, and the ground where they are found growing must be thoroughly drained before planting. It is sometimes necessary to trench it, but not always, as there are often spots where the trees can be planted. If the ground be well drained and the trees succeed, the rushes will soon disappear. The Reed (*Phragmites communis*) indicates a strong soil, sometimes inclining to clay, and sometimes to moss, but always full of vegetable matter, and surcharged with water, so much so that no trees will grow on it until the ground is drained. The situation is always in flat or hollow ground and sheltered. The trees most suited to this soil are Spruce, Alder, white and grey Poplars, Huntingdon, Bedford, and white Willows. Some of the best specimens of Willows are to be seen growing on soils where Reeds were once abundant. The treatment required before planting is much the same as that recommended for the Iris.

The Queen of the Meadow (*Spiraea Ulmaria*) and the wood Hyacinth (*Endymion nutans*) are plants indicating a deep loam or alluvial soil, sometimes with a sandy bottom inclining to clay; generally damp, but not so much as to hinder the growth of trees; of course, where too damp, it must be drained before planting. On this class of soil all the varieties of forest trees grow well. Some of the largest Poplars and Willows and best matured Oaks and Larches that we have ever seen were grown on this description of soil. Some of the Mosses are also sure indicators of soils. Conspicuous among these is the grey Moss (*Trichostomum lanuginosum*), so common on some hillsides. The presence of this plant is a beacon to the forester, warning him of "rocks a-head," in other words, not to expect great returns from any trees that may be grown in proximity to it. It is found growing on hill tops and mountains, where few other plants grow. It is also often found growing along with the common Heath, and the inexperienced may be led into a mistake as to the fertility of the soil, as some allow that trees can be grown wherever Heath will grow. No doubt, where the Heath is growing along with the Moss, it indicates an improvement on the situation where the Moss is found growing almost alone; still, wherever the Moss is abundant, a profitable crop of trees cannot be grown; but where (for the purposes of ornament, &c.), it is necessary to plant the ground, the trees most suitable are Scotch Fir, Pinus montana, Birch, Alder, Goat Willow, and Mountain Ash. Spruce can also be grown on the damp portions if the altitude is not too great. These will grow and have a fair appearance, but, as I have said, they will not be a profitable crop. The wood Mosses (*Hypnum*) are most common on ground where a crop of trees has been previously grown. They generally indicate a light, open soil, resting on whin or trap rock, suitable for growing Larch, Scotch Fir, Norway Maple, and Birch. In planting ground where these Mosses are abundant, it is necessary to pare them off before inserting the plant, as, if they are left, they absorb the moisture that should go to the nourishment of the plant. This does well when small plants are used, but when a successful crop is wanted on ground where a crop of trees has been previously grown, it is safest to have the ground pitted previous to planting. The white or Bog Moss (*Sphagnum*) is characteristic of wet, stagnant situations, with a considerable portion of porous peat in the soil. If thoroughly dried and solidified, it will grow fair specimens of Alder and Spruce, but to attain this, the drainage must be carefully attended to. The Hair Moss (*Polypodium commune*) is also invariably found in damp situations, but indicates a firmer and better class of soil than the last. The cross-leaved Heath (*Erica tetralix*) is generally in close proximity. The ground is always wet, but when thoroughly drained it will grow Spruce, Alder, and Scotch Fir, grey and Balsam Poplar. The soil is generally brown peat, naturally poor, and the subsoil gravelly, and sometimes soft bluish clay.

I have purposely omitted the nutritious natural Grasses so common in meadows and cultivated ground, as it is well known that these only grow upon a quality of soil that is seldom appropriated to the cultivation of forest trees; but on which all the varieties of trees seem to luxuriate. My aim has been, not to multiply indicators, but rather to select a few well-known plants that form positively an index to the kind of soils on which they grow, and, at the same time, so common as to be found in every district.—*W. Gilchrist, in Scottish Arboricultural Transactions.*

#### ROAD-SIDE TREES AND TELEGRAPH WIRES.

I AM glad that Mr. McNab has directed attention to this subject; for really the disfigurement is awful, and the loss of beauty irreparable. But it is more than a mere matter of beauty; it is also an interference with the rights of property. Let me state a case, and there are many such:—A small proprietor in a district of the south of Scotland much frequented by tourists for its picturesque beauty,

has a house with grounds and a small plantation at the roadside; also hedgerow trees along the sides of the road, of ninety or one hundred years' growth, bowing together overhead as they reach the gate, and carefully pruned to form a short arched approach. Some years ago, a series of peeled trees or long poles were quietly laid down along one side of the road, and by-and-by they were set up one fine morning before people were up; no leave was asked or obtained, and no money paid; the poles have iron wire guys fixed through the hedges into the fields, all complete. Last year cut branches were noticed thrown down behind one of the hedges, and it was seen that some pruners had been at work, in a small way, clearing the telegraph wires. This year, even during the rainy weather, it was found that a much more serious gang of destroyers had been at work—no leave being asked or obtained; large limbs were cut off the trees, and ornamental hedgerow trees have been converted into a series of hideous scarecrows. What remedy is there for these surely lawless proceedings? How indeed can a remedy be found for the destruction of trees? Man's life is not long enough to see them repaired, and no money can pay the value of such damage. The fields referred to might be let for building purposes, but what a loss to their value from this point of view, is the destruction of the trees! This is a free country, but who would expect that a freedom of this kind would be taken without some permission being asked or obtained.—*A Lover of Trees.*

LIFE: ITS DURATION IN PLANTS.

PLANT-LIFE may be considered under three general denominations. Some species are annual, or rather semi-annual, living from spring only to the close of the autumn of the same year; others are biennial, living to the close of the second autumn, but never beyond it; the greater part are perennial, or competent to live for a long series of years. Annuals include many of the commoner garden-flowers and culinary vegetables, which require to be freshly raised from seed every season; biennials are likewise common in gardens; perennials comprise all those herbaceous plants which form the staple vegetation of a country, withering, to a certain extent, during winter, and even dying down to the roots, but sprouting afresh with the return of spring; also all trees and shrubs, whether deciduous or evergreen. The perennials exhibit as great diversity in lease of life as the different species of animals. Some decay in as few as four or five years; others, often remarkable for their odoriferous and balsamic qualities, as Sage, Balm, and Lavender, endure for ten or more; next come the larger and robuster kind of shrubs, as Rhododendrons and Azaleas; then such trees as are of rapid growth, and the substance of which is soft, as the Poplar and Willow; and lastly, those mighty, slow-growing, solid-wooded pillars of the forest, as the Cedar and Oak, at whose feet whole nations rise and fall.

How vast are the periods of life allotted to longæval trees may be judged from the following list of ages known to have been reached by patriarchs of the respective kinds named:—

years.	years.	years.	years.
Cercis..... 300	Larch..... 576	Walnut..... 900	Oak..... 1,500
Elm..... 335	Orange..... 630	Oriental Plane 1,000	Cedar..... 2,000
Ivy..... 450	Cypress..... 800	Lime..... 1,100	Schubertia 3,000
Maple..... 516	Olive..... 800	Spruce..... 1,200	Yew..... 3,200

Four and five thousand years are assigned to Taxodium and Adansonia, and Von Martius describes Locust-trees in the South American forests which he believes to have begun their quasi-immortality in the days of Homer. Whether or no, it may safely be asserted that the world possesses at this moment living memorials of antiquity at least as old as the most ancient monuments of human art. How grand and solemn is even the thought of a tree coeval with the pyramids of Egypt and the sculptures of Nineveh, yet still putting forth leaves, and inviting the birds to come and "sing among the branches!"

NOTES AND QUESTIONS ON TREES AND SHRUBS.

**New Ornamental Cherry.**—A remarkable sport of the May Duke Cherry has been produced in the grounds of M. Ferdinand Messange, of Bouillonville. The leaves become narrow at the end, so as to resemble those of the Peach, or even the Willow. Some are 5 inches in length and an inch in width; others are 6 inches in length, and about the third of an inch in breadth.—*Belgique Horticole.*

**Rabbits and Conifers.**—It is difficult to get two people to agree as to the trees with which rabbits and hares meddle. One of your correspondents says, "Rabbits and hares cut Pinus Laricio very much if planted small, but do not touch Pinus austriaca." Now, as for the latter, I can confidently assert that they cut it more than any other of the Pine tribe. With me they have attacked and thoroughly destroyed fine plants of it 4 and 5 feet high. A neighbour who has planted P. Laricio largely (I have none except guarded) says that it is rabbit proof, and, on his assertion, I am planting some hundreds of it this season. The fact is, I believe, in a really severe season rabbits will attack anything—in a deep snow I have had Yews eaten down—but in the generality of years certain things escape.—*A SOLDIER.*

THE GARDENS OF THE ANCIENT ROMANS.

(Continued from p. 550, Vol. II.)

The hint given by Virgil was taken up by Columella, a poet who seems to have flourished during the reign of Claudius, or some time during the first fifty years of the Christian era, and who wrote a long poem upon the same subject as that of the Georgics, closely copying the style, the language, and the imagery of his great master; chastely and elegantly without doubt, but still only copying. In the tenth book of this poem, he devotes a considerable space to what Virgil had proposed, but when at the end we are very little better informed than before beginning. As for the other Roman poets, they make no more than passing allusions to gardens; and were it not for the minute and extended description given by the younger Pliny of his summer villa in Tuscany and its surroundings, we should positively have no exact written account whatever. This beautiful retreat was situated in an amphitheatre of the Apennines; its owner was a philosophic patrician of literary tastes, and there can be no doubt that the garden itself was laid out according to the very best ideas in vogue at the time. The date of the description would be about A.D. 95, or in the reign of Trajan. In one part you have a little meadow; in another a walk is bordered with Acanthus; beyond is a knot of dwarf Planes. The Box trees, which thrive upon every side, are cut and clipped into the artificial shapes called "topiary work." Fruit trees are used in plenty, alternating with obelisks or statues; presently we reach an alcove shady with the green of Vine leaves. Water is introduced freely, many little fountains, each with its marble basin, refreshing the atmosphere. Besides these, there are spaces for simple games, with plenty of marble seats, where the friends of the noble proprietor can rest themselves and enjoy the scene. So far the illustrious Pliny; and so far, no doubt, the scene described was very charming in its way. But how little about flowers! The delight of the garden seems to have consisted in its plentiful shade, its alleys and plots of green, the consummate order and neatness, the rich infusion of works of art, sculptures in marble that would put the verdant ones to shame, the sense of moving water, always agreeable and soothing, the feeling of seclusion, and that incomparable one, leisure to enjoy. At the same time it was essentially stiff, rigorous, and formal; in some respects, it would seem, geometrically precise. Many, perhaps all, of the highest class Roman nobles possessed gardens of similar character, either at their country seats or close to the city, allusions to them occurring in Claudian, Seneca, and other writers, but still the intimations as to their contents are meagre in the extreme, and what we read of least is the *flower portion*. Fortunately for our curiosity, there is another source of information, limited, but quite as trustworthy—that which is supplied in the ancient paintings uncovered at Herculaneum and Pompeii. Like their antetypes in the Egyptian tombs, in the midst of their inexpressible mournfulness of association, these, at all events, speak the truth. Take, for example, the pictorial representation of a garden in Sir W. Gell's Pompeiana, part 2. Here is portrayed much of what Pliny indicates, but on a smaller scale, and omitting many of the best elements; here are the hedges of Box or Rosemary, the larger evergreens, such as the Bay and the Cypress, the pots and boxes along the edges of the pathways and upon the window-ledges, and the general geometrical idea which furnished, from another source, the models for the Dutch gardening of the seventeenth century, and from which, though it struggled hard for life, we may be thankful our present age has been nearly liberated. The practice in the Roman method of gardening which would now be most generally disapproved, would probably be the clipping of the evergreens into likenesses of animals, columns, statues, &c., though the practice survived for so long a roll of centuries as to obtain almost a freehold right, and in special corners is still extant. Among the Romans themselves were men keen enough to detect the error of so maltrating shrubs, the proper outlines of which we may presume are best known to nature, who first traced them, since, in another of the epigrams of Martial, not only is ridicule cast on the ranks of Laurel and Cypress, but more vigorously yet on the tortured Box trees. Martial was right. To mutilate a tree or shrub unnecessarily, to pervert and obliterate its natural outlines, is

every bit as indefensible as "cruelty to animals," and a deed that ought to be included in a horticultural penal code. It has been said that there is no cruelty which a bad-hearted man will not inflict upon a brute creature, so long as the unfortunate beast does not cry out: perhaps if the trees and shrubs possessed voices, the "topiarian art" would have been practised somewhat less. It began with the admirers of gladiatorial combats, and of the sanguinary sports of the Coliseum—with Pagans, in the dictionary of whose language the word "tender-heartedness" does not occur; with these it should have been left; to their memory it should now be consigned. There is only one thing worse horticulturally than the ancient Roman mode of shrub-torment, and that is wilful and reckless arboricide, especially when the tree destroyed stands where the like of it can never grow again. Many and great were the services rendered to taste by Alexander Pope, but never was there a sounder one than in the satire where he addresses himself to this topiarian art.

His gardens next your admiration call;  
On every side you look, Behold the wall!  
No pleasing intricacies intervene,  
No artful wildness may perplex the scene;  
Grove nods to grove; each alley has a brother,  
And half the platform just reflects the other.  
The suffering eye inverted nature sees,  
Trees out to statues, statues thick as trees;  
With here a fountain never to be played,  
And there a summer-house that knows no shade.

Use the pruning-knife and the shears by all means. The unshapely, the untidy, the incompatible, are always to be corrected, and kept in check. Let nature be as *déjàgâé* as you like, but never unkempt and in *deshabille*. Shakspeare has given us sweet and sound enough lesson as to that, in the beautiful passage wherein he calls our little island our "sea-walled garden," for garden it truly is; and when a man wants a pattern for his private *hortus* he cannot do better than mentally survey an average English county, with all its varied charms of nature and art, bringing together in harmonious order the spontaneous and the polished, and leaving no element untouched that has been the pride and property of old England since it "arose from out the azure main." Even formality and straight lines are not at variance with the perfection of gardening. The right course is to employ them in the right places. Broad terraces near the mansion; noble avenues of aspiring trees; green corridors that take form almost of their own accord, like the aisles in a cathedral; these rank with the proprieties of all truly artistic gardening, and are always springs of delight to a hospitable and polished mind. What is odious is neither precision, nor geometry, nor the use of cold steel, but the malversation of nature's grace into the semblance of a casting from a foundry, or of a corps of trim militiamen on parade.

The redeeming feature in the topiarian art, as practised in the Roman gardens, was that the workman was allowed at times to cover the walls and terraces of his employer's villa with ivy, leading the same elegant climber, when convenient, into the trees. How beautiful is this gracious plant, balanced upon some ancient bough, overhanging a ravine or a stream! or if it do but play the centipede, and keep to the main trunk, with those matchless and sinuous creepers, and leaf-angles in every attitude that is possible to joyous freedom. Either way, any way, still how perfect! We must forgive the Roman noble for his Box-tree clipping, since he loved old *Hedera Helix*. An act of kindly grace should always be the first to think of, and this leads us to inquire what were the merits of the Roman gardening. Anything that takes a deep hold upon a people's fancy must needs be founded upon something better than mere caprice, and certainly not wholly upon ignorance. Because landscape gardening, in our modern sense of the term, found no favour with the Romans, and because a display of floral beauty seems never to have been imagined, we are not, by any means, to look with contempt upon the Roman gardening. No man will do so who is just and consistent, seeing that it aspired to realise a kind of beauty totally different from that which engages the cultivated taste of our own period; under special circumstances, perhaps, it possesses recommendations which entitle it to a certain degree of practical observance even now. The Roman style of gardening,

though greatly advanced in comparison with that of the Egyptians, was a thing of the childhood of horticulture; yea, of the childhood, in many respects, of human progress; for, let us consider a moment, and we cannot but allow that the times commonly called the "old" ones were, in reality, the *young* ones. When geometrical gardening was invented, and regarded as perfection, science and floriculture were only finding their feet. The times we live in are the genuine "old" ones, and, as Lord Bacon said long ago, we who inherit the gathered wealth and the traditions of fifty ages, are the real "old" people of the world. Geometrical gardening is a purely inventive art, in a certain sense resembling architecture, and is governed by similar principles, the art being everywhere avowed. Landscape gardening, on the other hand, is like painting and the drama, which directly imitate nature, but studiously conceal the art by which the end is attained. The hand of man should be as visible, nevertheless, in gardens laid out in the natural style as it is in the geometric, only after another fashion; since for the consummate feeling of the beautiful, it is essential that we should recognise in it some expression of human intelligence. An extended prospect of mountain, valley, woods, plains, and a shining river, let the components be wild, grand, or romantic as possible, is never so delightful in its untouched condition as when it presents traces of thought and science. Look down from the slopes of the glorious mountains of the lake district, or of North Wales, or of Connemara; then from the sweet green thymy hills of Surrey or Somersetshire, and note the contrast with the wilderness of the peculiar charm conferred by the spectacle of orchards and farmsteads, the arches of the dimly-seen railway viaduct, the pearly clouds that tell of the passing locomotive. If this be true of the "sea-walled garden," none the less true is it of the miniature one, which even in its least cultured parts becomes animating exactly in the degree that it breathes consciousness of the touch and genius of a nature greater than itself. To a certain extent, geometric gardening also imitates nature, but the imitation is conventional, or after the fashion of that displayed in carpets and parlour-wall papers.

It follows that the more that either of these two styles is improved, the more widely will it differ from the perfection of the other. Also that while landscape gardening possesses qualities peculiar to itself, so likewise does geometric gardening, each style being the outbirth of the times in which it flourishes, and bearing a certain relation to the general temper of the country. The gardening of the Romans was perfectly natural to them, regarding the circumstances in which they were placed; and as it satisfied their wants, and supplied aspects which they deemed beautiful, the idea of a garden was, so far, perfectly realised.

Gardening, in a word, as an art of design, must be judged of in reference to the climate of the country, and to the habits and manners of the people, quite as much as by the light of the first principles of natural symmetry and beauty. Divested of certain adjuncts proper enough to climates warmer than our own, and purified of its decorative extravagances, the idea of the Roman style of gardening cannot be regarded as absolutely devoid of merit. A sorrowful day for England and for horticulture would it be, should public fancy ever relapse towards it upon a large scale;—that, however, is a danger there is no occasion to forbode;—all we contend for is that regarded from a Roman's point of view, it had abundant justification, and that should Romanising ever become proper in England, the models left by the Romans are unimpeachable.

The truest idea, the essential and fundamental one of the whole matter, consists, after all, not so much in the fact of landscape-gardening being the antithesis of the geometrical, as in its abiding by the principle laid down by Quatremère de Quincy, that "to imitate in the fine arts is to produce the resemblance of a thing through the medium of some other thing, which becomes an image of it." Just this and no other is it which distinguishes between the artist and the mechanic; the former gives an ideal copy, the latter only a fac-simile. Applied to horticulture, of course understood as practised on a large scale, De Quincy's axiom would imply the extensive and tasteful incorporation of exotic trees and flowers; the exclusion of nothing but what is weedy and coarse, and the encouragement of everything that is graceful and pretty, and

that shall seem to be the original sowing of nature's own hand. The greater the variety of forms, and hues, and boundary lines, the more classic the physiognomies, and the more liberal use, at the same time, of what is often quite as foreign, practically, as a plant from the antipodes—the flora of the English woodland—so much the more picturesque will the garden become: so much the more perfectly will nature and art be harmonised, and the privilege of humanity be vindicated. Rarely are single and solitary ideas fruitful. All beauty and perfection come of duality; a genuine garden infallibly reminds one of that ancient and innocent union which received the first blessing of God, both illustrating at the same time that most lovely line of the Laureate's—

“Like perfect music set to noble words.”

Not that the beauty of a garden calls for the indiscriminate crowding together of all sorts of trees and plants. This is to induce failure in one principal source of beauty, wherever we may seek it, namely, a complexion of warm and rosy health. The beauty comes of the choice and the adjustment. Good

## THE LIBRARY.

### SMALL FRUIT FARMS.\*

HOW THEY CAN BE MADE TO ANSWER.

This is an excellent little book, the object of which is sufficiently clearly indicated in the title. The author rightly thinks it a pity that the class intermediate between the labourer and large farmer should have disappeared, and he clearly shows how it is possible to make small holdings in England pay well as fruit farms. The following on Plum culture will show how capable the author is of treating the question from the above-mentioned point of view:—

#### PLUMS.

We will now pass on to the larger kinds of fruits, from bushes to trees, such as Plums, Apples, Pears, and Cherries; and I put Plums first of all in my list, because they produce a much earlier return than the others: indeed, so much so that it would pay a tenant to plant them on a fourteen years' lease, whereas the others, if planted

Epiphytes on a Prostrate Tree.

gardening, in a word, depends less upon quantity of plants, and expenditure of bodily strength, than upon well-educated labour of the brain. Industry is good, but a thinking head is better. The mistake too frequently committed is that of confounding plethora with wealth, and mere ornament and tinsel with pure and original beauty; and one of the weakest forms it assumes is that which gives leave only to a certain set of legalised things to come in, nine-tenths of nature's loveliness being consigned to a sort of *Iudeu Expurgatorius*. LEO GRINDON.

#### EPIPHYTES ON A PROSTRATE TREE.

OUR illustration of a prostrate tree in a Brazilian forest, covered with Arads and other epiphytal plants, shows a frequent and interesting aspect of vegetation in the hot and moist regions of South America. Many of the great creeping Arums, and other easily grown stove plants now in cultivation, might be used with good effect in forming miniature pictures of the same type in our hothouses, allowed to grow on rough branches, or arranged on rockwork.

on the usual orchard stocks, are a landlord's improvement, and in most cases are planted for the benefit of the next generation. The Apple, Pear, and Cherry, on the usual orchard permanent stocks, do not become sensibly profitable till they are twelve or fifteen years old; whereas the Plum will produce a good return after six or seven years, and some sorts even earlier than this. The most profitable way of planting Plums will be to put them in together with Currants or Gooseberries at intervals of 24 feet, which will take seventy-five trees to the acre, or even at intervals of 12 feet, which will take 300 trees to the acre. When the Gooseberries or Currants are wearing out, which will be in fifteen or twenty years, the Plums will have covered the ground, and will bring an ample profit. I find that trees of the Pershore Egg Plum, which I planted in 1865, have this year produced on the average 30 lbs. weight of fruit each, which, at the rate of 5s. per pot of 90 lbs., is a return of 1s. 8d. each tree. The mention of this pot reminds me that in the Midland counties all fruits and vegetables are sold wholesale by the "pot," as it is called. A pot is an oblong basket with a handle at each end, and without a lid. All the pots have these points in

\* "Small Farms; How they can be made to Answer." By the Rev. W. Lea, M.A. London: 171, Fleet Street.

common, and being in such universal use, one would have supposed that they would have a still more important point in common—I mean a fixed and definite capacity; but this is not the case, there are pots and pots. This was one of the first lessons I learnt in farming: on going to buy some pots I was asked by the maker whether I wanted buyer's pots or seller's pots; and on inquiring the difference, I was informed that buyer's pots were larger pots, and seller's pots smaller pots, and that there was a difference of nearly a peck, or one-fifth, between them; and the different capacities of pots are so well known, that a remedy has been invented which is almost as bad as the disease. A certain conventional weight is required for a pot of every variety of fruit or vegetable; and if these weights were the same in different districts, there would only be the trouble of keeping the different weights in one's head. But this is not the case—the weights vary in different parts just as much as pots do; a pot of Potatoes is 95 lbs. in one place, while twenty miles away it is only 80 lbs. A pot of Plums varies even more than this—in one part it is 90 lbs., in another 72 lbs. The true remedy would be to buy and sell everything by weight, irrespective of these fictitious measures, which vary in every district. So much for pots. The question we have to consider is, what varieties of Plum will fill them soonest, and bring the best return to the planter?

#### PROFITABLE MARKET PLUMS.

Now, this question will be answered differently in different districts. In some it will be the Prune Damson, in others some other variety which has proved itself most congenial to the soil; but wherever the soil is strong and retentive the Pershore Egg Plum should form a considerable portion of every plantation. It is the hardiest of all Plums, the surest cropper, and the wood is tough, and the branches will bear an enormous weight of fruit without breaking. It is said to be a short-lived tree; but I know trees in full vigour which have been planted at least a quarter of a century. It brings a lower price than other Plums, but I think, in the long run, it will pay better than any other on the average. In fact, Plums for market purposes may be divided into two classes—yellow or Egg Plums, and coloured Plums; the latter in most years are worth nearly double the price of the former. Among coloured Plums the best are the Victoria, the Prince Englebert, Pond's Seedling, the Black Diamond, Belgian Purple, Kirke's Plum, Cox's Emperor, commonly called Jenny Moor, Prince of Wales, Cluster Damson, Mitchelson's Damson, and the Belle de Louvain. The Victoria is a bright, large, pink Plum, an enormous cropper, always in demand, good for eating or cooking, still better, I am told, for bottling for use in spring; but it has one most serious drawback—the wood is extremely brittle, and my trees break every year under the weight of fruit. This, perhaps, may be in part owing to their being what is technically termed "standards for orchards"; and if I were to begin again, I would have nothing but "half-standards" grafted about 3½ feet from the ground, and then I should prune back till the lower branches were strong enough to bear the fruit. But notwithstanding this disadvantage, the Victoria should have a place in every plantation for its beauty and productiveness. I once saw long lines of this Plum alternating with Pond's Seedling; they were both ripe, and as the sun shone on their large pink fruit, which hung the size of eggs from the boughs, I thought I never saw a more beautiful sight. The old Greek sailors never imagined anything finer in the gardens of the Hesperides.

Pond's Seedling has the reputation of being an uncertain cropper, but with me it always bears freely, and produces finer fruit than any of the thirty sorts I have in my plantation; its wood, too, is tough, and will bear a large crop without breaking. Prince Englebert is an excellent black Plum, and an abundant cropper. The Black Diamond possesses the last of these qualifications, but after all it is a monstrous abomination. Rivers' Early Prolific is in some places a profitable variety, and, being the first in the market, usually realises a high price to the grower, but I cannot speak much of it myself, as I have been unfortunate in my trees. The nurseryman from whom I bought them sent them on what I believe to be Almond stocks, and the result is that they have not made any growth in the six years, and I am now about to root them up and burn them. This and other like experiences in buying trees lead me to offer a word of advice to intending planters on this head. I know nothing more disappointing, when a plantation has been made, than to find, when your trees come into bearing at the end of three or four years, that the nurseryman has sent them on bad stocks, or sorts untrue to name. It has been my misfortune to find this to be the case on several occasions. When I began, I ordered trees from several nurserymen, and after waiting some years I found, to my disgust, that what ought to have been choice Pears are in some cases nothing better than perry fruit, and Plums in like manner untrue to name. I should therefore recommend purchasers to visit the nurseries when the trees are in fruit and select for themselves.

#### PLUM TREE ENEMIES.

The blackbird is mischievous, and in August and September the wasps and hornets are troublesome; but the most destructive of all enemies is the grub of the *Cheimatobia brumata*, or Winter Moth. This moth makes its appearance about the end of October, and continues on the trees till the end of the year. The male is a small-winged moth, the female a wingless abomination, not unlike a bug, but longer in the leg and lighter in colour. She lays about two hundred eggs, either round the buds of the Plum or Pear, or in the cracks of the bark. These eggs are hatched in April, and a small caterpillar appears, which eats its way into the centre of the opening bud, and destroys all prospect of fruit. By the end of May it is full grown, and then lets itself down by a thread to the ground and buries itself in the soil, where it becomes a chrysalis. In this state it remains till the end of October, when it emerges again in its winged state.

This grub is the Plum-grower's greatest enemy, and many plans have been attempted for its destruction, the most successful being the encouragement of small birds, and if they were sufficiently abundant I question if anything farther would be required. In 1865 I bought some trees from the neighbourhood of the Vale of Evesham, which is the head-quarters of this Winter Moth, and on examining them in December I discovered that I had bought some moths with them, for I caught ten female *Cheimatobias* one morning; but since that year I have never seen a specimen of them, and I conclude that the small birds, which are plentiful, have completely extirpated them; but where they are not so abundant, artificial means must be adopted. The fruit-farmers and their men turn out at night in November, with lanterns, and kill the moths by hundreds on the stems of the trees. Hundreds more of the females are caught, as they climb the trees, in a mixture of tar and grease, with which the stems are smeared, and in some instances it is found necessary to pick the trees and destroy the caterpillars by hand; but all these means are troublesome and expensive, and I think would be unnecessary if a sufficient number of small birds could be induced to settle in the plantation.

#### DEVONSHIRE COTTAGE GARDENS.

Nothing can be prettier than the gardens attached to the thatched cottages in Devonshire. They are frequently to be seen on the side and oftener at the bottom of a hill, down which a narrow road leads to a rude single-arched stone bridge. Here a shallow stream may be seen flowing rapidly, and which now and then "stieckles," to use a Devonshire phrase, over a pavement of either pebbles or rag-stone. A little rill descends by the side of the lane, and close to the hedge of the cottage, which is approached by a broad stepping-stone over the rill, and beyond it is a gate made of rough sticks, which leads to the cottage. At a short distance, an excavation has been cut out of the bank, and paved round with rough stones, into which the water finds and then again makes its way, clear and sparkling. This is the cottager's well. His garden is gay with flowers. His bees are placed on each side of a window, surrounded with Honeysuckles, Jessamine, or a flourishing Vine, and the rustic porch is covered with these or other creepers. Here, also, the gorgeous Hollyhock may be seen in perfection, for it delights in the rich red soil of Devonshire. Giant Stocks, Carnations, and China Asters flourish from the same cause, and make the garden appear as though it belonged to Flora herself. Nor must the little orchard be forgotten. The Apple trees slope with the hill, and in the spring are covered with a profusion of the most beautiful blossom, and in the autumn are generally weighed down with their load of red fruit. Under them may be seen a crop of Potatoes, and in another part of the garden those fine Paington Cabbages, one of the best vegetables of the county. In a sheltered nook is the thatched pigstye, partly concealed by the round yellow-faced Sunflower, which serves both as a screen and as an ornament. The mud or cob walls of the cottage add to its picturesque appearance, when partly covered with creepers and surrounded with flowers. Such is an accurate description of one of the many cottages I have seen in the beautiful and hospitable county of Devon. Those who, like myself, have wandered amongst its delightful lanes will not think my picture overcharged.—*E. Jesso.*

**Protection Against Worthless Fertilizers.**—New Hampshire has adopted a law to regulate the quality and sale of commercial fertilizers. The manufacturer must file a bond with the State Treasurer in 10,000 dollars, payable to the State, but with a condition that it shall be void upon compliance with the law, which requires that all fertilizers offered for sale shall be accompanied by a statement naming the date of manufacture, and the per centage of ammonia and other constituent parts. If these shall prove to be false (which is to be tested by the State Assayer on due application) a fine of 500 dollars is imposed on the seller, to be presented for by the Attorney-General or any county solicitor. A fine of 200 dollars is imposed for offering fertilizers for sale without a license.

## GARDEN DESTROYERS.

### A CABBAGE BUG.

(STRACHIA ORNATA).

THAT portion of the bug tribe known to entomologists as the Heteroptera supplies few recruits to the great army of insects that prey upon the food of man, and compete with him for its possession. There are, however, some which do mischief, and the species which is figured (of the size of life) on the Cabbage-leaf in the woodcut is one of these. Not that we can say that it does harm in Britain, for there it is fortunately rare. But on the continent, and more particularly in some parts of France and the south of Europe and Algiers, the injury it does is sometimes considerable, and this is not confined to the actual injury done to the leaves by sucking their juices, but extends to the unpunctured leaves which it may have frequented, or on which it may have been crushed or squeezed.

The reader may not be aware that every individual of the bug tribe, from the large metallic and gaily-adorned species of tropical countries down to the smallest species in the most northern countries, are all distinguished by a peculiar odour—that of the common bed bug. This species has it abominably strong, and where it rests it makes the vegetable unentable. We well remember the youthful surprise with which we first learned this fact by experience. We had received a bottle full

A Cabbage Bug.

of insects in spirits from the East Indies, among which were a number of beautiful large bugs, and the odour which remained on our fingers after handling and pinning these was such an intensified essence of bed-bug, and so difficult to get rid of, that we have never forgotten it. What the nature of this odour is is still a problem, but notwithstanding its abundance in some quarters, we doubt if it would be possible to procure a sufficient quantity of material to analyse or experiment upon for the chemist. There is indeed a popular tradition that the bed bug is one of the ingredients of "Soy," and if that be true, the material must be procurable in commercial quantities; but we have always regarded this as an unfounded aspersion upon an excellent sauce.

Various species of scutate Heteroptera (that is, bugs with a large shield, covering, to a greater or less degree, their wings) feed upon the Cabbage; and the present species, and one or two allied species, are specially devoted to it. The eggs are laid on the under-side of the leaves in close little bands. Individually they share the beauty of the parent insect, and have it in something of the same character, well-defined black spots on a lighter ground. They look like little barrels, of which the top and the bottom are encircled with brown bands, while the middle is grey, marked with small, very round black points. When the egg is hatched, the insect inside pushes up the upper part of the shell, like a little lid, and, coming out, at once begins its work of feeding on the leaves.

The bugs, as the reader of course knows, have no mandibles

or jaws, or rather these are converted into a sucking apparatus. Consequently the form their ravages take is not that of gnawed or skeletonised leaves, but of leaves riddled by little wounds, which render the leaf rugose, and covered by dried spots. The insect plunges its sucker into the parenchyma of the leaf, and sucks up the juice, as the bed bug does the blood of its victim. The larva is very similar in appearance to the perfect insect, with the exception that it has no wings. The insect is sufficiently accurately represented in the woodcut to render a description unnecessary. The paler parts are vermilion red, sometimes shaded with yellow, and the dark parts black. They are thus very visible, and may be easily caught and destroyed, but the under-side of the leaves must be looked at for the eggs. A. M.

**An Efficient Rat Trap.**—May I suggest to your correspondent "E. D. T." a very effectual way of disposing of the rats and mice in his garden. I have known it to destroy between fifty and one hundred of these pests in a single night. Take a large plant pot, say 3 feet in diameter at top and 3 feet deep; sink it into the ground till even with the surface, and place about 1 foot of water in it. Then take a deal board 3 feet long, 6 inches wide, and half an inch thick; saw off 1 foot of it, which must be smoothly planed and refastened in its place with two *easy-working* brass hinges; then fasten a weak steel spring on to the longer part of the board and reaching over the saw-cut on to the shorter part, so that by holding the board out horizontally, the spring will just hold this shorter part of the board on a level with the rest. The spring must, however, be only strong enough to do this and a very little more. This trap fall is then placed half-way over the pot of water, and a large stone is placed on the other end to hold it firm. The "drop" is then well greased on the planed side, and some *strong-scented* bait is nailed on to the extreme end. The rat will walk on to the "drop," which will not yield till he is fairly on; one step more, and down he goes into the water, the "drop" returning into position for another customer. If watched, it is amusing to see the efforts of the rats to retrace their steps, which, if properly managed, the trap never allows them to do. It is better to put something in the water, as quick-lime for instance, which will suffocate the rats speedily. "E. D. T." should put several of these traps into the ground in his garden.—PRESTON POWERS, Florence.

**Garden Destroyers in India.**—A communication from Agra, dated the 12th ult., says:—"The crops in the Agra district were in such splendid condition, that cultivators were looking forward to a good harvest and a profitable out-turn. In a few short hours their hopes were blighted. A dense crowd of locusts came up from the south, and, after hovering in the air for some time over the city, they suddenly descended, and, covering the surface of the earth, of the trees, and of every particle of vegetation, they commenced their work of destruction, choosing more especially, as their most choice morsels, the youngest and most delicate leaves of trees, the choicest and most valuable of plants, and, what is more sad than all, devouring the green ears of grain just beginning to ripen. So thick was the crowd of locusts that the sun was completely hidden, and a partial darkness prevailed. The natives used all endeavours to dislodge the unwelcome visitors, but failed. They remained for some time, and then started in a northerly direction. A magnificent grove of trees has been utterly denuded of leaves, the grass has been cropped short, and whole gardens have been completely destroyed. Near a village called Uchennarra, on the Bhanpore road, eighteen miles from Agra, the crops have been completely ruined, and such has been the damage done in other parts of the Agra district, that it is estimated that the out-turn will be 50 per cent. less than was expected before the locusts arrived. In this sublunary sphere it often happens that evils which are the causes of unmitigated sufferings to some creatures, cause joy and delight to others. The crows, kites, sparrows, and hawks, banqueted and feasted in a princely manner during the stay of the locusts, and many of the natives in the city captured them in basketsful, and afterwards feasted on them. I am informed that they make capital curry, and that they are very similar in flavour to prawns."

**Peach Tree Insects.**—Often a mass of gum is found at the base of young Peach trees, and small white worms are found in the bark beneath, which are the cause of the gummy exudation. They do not penetrate deep, and are not very injurious to the tree. The Washington Department of Agriculture report says they are the larva of the *Mycetophila persica*.

**Rats and Mice.**—Having had whole crops of Melons destroyed by rats, and having tried traps and poison with but bad results, this year I got two young cats early in the spring and kept them in the garden, and I have had no annoyance from rats or mice since. I would, therefore, advise your correspondent, "E. D. T." to try them. If he gets them young they will not seek to go away, at least ours don't.—D. M.

## THE PROPAGATOR.

### RAISING PELARGONIUMS.

MR. SISLEY, well-known as the originator of several choice varieties of double zonal Pelargoniums, describes his practice thus:—My friend Carrière, speaking of my double white zonal in the *Revue Horticole* of October 1st, says that it is the result of scientific combinations. I must decline to accept this encomium, and am willing to make the horticultural world acquainted with my very simple practice, which I have never kept a secret. When, six years ago, I began the artificial fertilisation of zonal Pelargoniums, I procured about fifty of the best varieties of single-flowered zonal Pelargoniums of different colours, and about 200 plants of the then existing double-flowered varieties. And until 1870 I continued to buy all the new double varieties that were brought out, and all the single-flowered sorts which were of different shades from those in my collection. Without any preconceived theory I fertilised all the single-flowered with the pollen of the double ones which had stamens. For three years I did not obtain a seedling worth mentioning, and I was on the eve of giving up artificial fecundation, when in 1869 I obtained *Victoire de Lyon* and *Clémence Royer*, which, although not perfect in form, were very different in colour from any double zonal Pelargonium then produced. This led me to continue my efforts. I have not learned by my practice anything that can be called a theory, because among my seedlings coming from the same mother and the same father I have found them all differing from one another. My double white is the produce of a single white (one of my seedlings second or third generation) by a double red; but four other seedlings from the same fecundation are either white, pink, or red, and all single flowers. And in this there is nothing astonishing. Why should the laws of nature vary and act differently in the vegetable world from what they do in the animal world? Nature and science have not yet taught us why the offsprings of the same father and the same mother are always different from one another, notwithstanding their family likeness. And it is very likely that man will always be ignorant of this. The only thing I know, and every horticulturist knows, is that to obtain double flowers, single flowers must be fertilised by double ones.

### PROPAGATION OF TREE CARNATIONS.

My plan of doing this differs entirely from that of "Quo." I propagate tree Carnations by means of cuttings to the extent of many thousands every season, and as I can depend on every cutting making a good saleable plant, I beg to recommend this method, which I find so successful. I have a box or pan well drained, and filled with compost as recommended by "Quo," taking care that the mould used is free from wire-worm. I place the box in a bottom heat of 75°. I trim the cuttings carefully; but do not cut off the ends of the leaves as many do, and I place them firmly in the mould, an inch or more apart, as suits my requirements. The glass with which they are covered must fit so as to be perfectly airtight. Before putting it on give the cuttings a thorough drenching with rain-water with the chill off, till the mould is like mud; then put the glass on at once. Leave all undisturbed for three weeks, but water all round, if need be, to prevent the cuttings from getting dry. By the end of the three weeks, all will be found to be growing; give another week's grace, then remove the glass, and pot them off in small 60-sized pots. Replace them in a gentle heat, in order to start them, and give them plenty of water. I have frames that each hold three hundred plants, and it is rare, indeed, to find one without good roots. With "Quo's" remarks on the evils of permitting them to get pot-bound, I decidedly differ, as I can get as good blooms from plants in small 60-sized pots as from those in larger pots; and from experience I am quite satisfied that manure or manure water is poison to a tree Carnation. The compost mentioned and an abundant supply of water during every stage of growth are all that Carnations want. "Quo's" selection of varieties is good; but it should have included "La Belle," a pure white kind, very free, and a perpetual bloomer. E.L.

**Grafting Acers.**—In the *Wochenschrift* Professor Karl Koch relates some interesting observations respecting grafting noticed by himself in the nurseries of MM. Simon Louis, at Metz. Acer ginnala, which has been recently discovered in Amooria, does not succeed when grafted on *A. tataricum*, which is, nevertheless, so closely allied to it that some botanists consider the two as forms of one species, while it succeeds perfectly when worked on the *A. pseudo-Platanus*.

**How to Increase the White Wistaria.**—How is it that this plant is so scarce? True, there is a little difficulty in multiplying it, but if the following method is employed, the results will be most satisfactory. It consists in making cuttings from the roots, precisely in the same manner as is done with many other plants, such as *Aralias*, *Tecoma*, &c. It may also be remarked that plants thus multiplied are far more vigorous than such as are grafted, which is generally the means used for the propagation of the white Wistaria. This mode of propagation may be also used with equal advantage in the case of the common Wistaria.—M. MILLAUD.

## THE INDOOR GARDEN.

### ACINETA HUMBOLDTI.

NOBLE Orchids are the *Acinetas*, all the species of which are beautiful and worthy of cultivation. They are all epiphytal and natives of tropical America. There are several species, but *A. Humboldti* is the one best known, and is perhaps the finest of the family. It is strong-growing, producing large angular pseudo-bulbs, and ample ribbed leaves. It was found in Venezuela, from whence it was introduced into England in 1841. It requires a tolerably high temperature to have it in perfection, and is consequently grown in the East Indian house or in the warmest part of some intermediate house; but in places where there is only one Orchid house it may be successfully cultivated in the warmest end of it. *Acinetas* should be grown in baskets suspended from the rafters or in baskets shaped somewhat like a wine glass, the stem of which should be an inch or two in diameter and two feet high, with the basket fixed vase-like at the summit, and resting on a base sufficiently wide to prevent the whole from being readily upset. It is absolutely necessary to employ baskets for *Acinetas*, as they produce their flowers on pendulous racemes from the base of the pseudo-bulbs, and push downwards like *Stanhoopes* through the compost until they reach the light, when they lengthen themselves sufficiently to develop all their flower buds.

The flowers of *A. Humboldti* are of a deep chocolate colour minutely spotted with crimson; they are thick and wax-like in substance, and commonly produced in May and June. Although in the annexed illustration only one raceme is visible, I have seen four much finer spikes all in perfection at one time on one plant. This specimen was in Mr. McLeod's collection at Dalvey, in Morayshire, and was grown in a wine glass-shaped basket or vase, made of erect, light, wooden bars 6 inches apart, and held together by copper wire. When in flower water should be carefully applied, for should it get spilt over the blooms, their beauty becomes much impaired.

A compost consisting of good turfy peat and roughly-chopped *Sphagnum* is well adapted for all the species of *Acineta*. They make their growth in spring and summer, and during that period should be liberally watered and syringed twice a-day; atmospheric humidity is likewise necessary. Throughout the winter months they should be kept pretty dry, but not too much so. A light sprinkling overhead once a week, on fine days, during their resting season, is also beneficial. They may be shifted, if necessary, in February; but generally the looser portions of the old compost are merely removed and replaced with fresh material. If it be necessary to increase the root room, a shift is given; or if increase of stock be aimed at, the plants are shaken out and divided, and the individual portions put in separate and smaller baskets. Should the wires be too far apart to retain the compost, it may be secured by means of pegs made of the common Brake. Beech pegs are frequently employed for this purpose, but I know of nothing superior to those of the Bracken, wooden pegs being productive of fungi.

The elegant sprayey drapery that clusters about the basket in the accompanying illustration consists of *Selaginellas*, *Maiden-hair* and other light graceful Ferns, and a few other stove plants that will grow anywhere. It is seldom necessary to plant these, for if the Orchids are placed in the vicinity of such plants, the exposed soil in which they are grown soon becomes furnished with self-sown seedlings. If it be requisite to accelerate the growth of such drapery, and to enhance its beauty by greater variety, the following may be inserted between the wires, viz.:—*Selaginellas* of the *Krausiana* and *Mertensii* sections, and other graceful kinds not of a too robust nor of too dwarf a habit, *Coccoypselum repens*, *Panicum variegatum*, *Torenia asiatica*, *Achimenes picta*, *Tradescantias*—the creeping ones, and *Streptocarpus Rexii*, which, although not a creeper, is admirably adapted for suspended baskets. Many other little plants might be likewise advantageously utilised in this way. Amongst Ferns, the airy *Adiantums*, little *Gymnogrammas*, which, notwithstanding their farinose leaves, thrive excellently; *Doodias*, little *Pterises*, *Davallias*, *Polypodiums*, a few *Aspleniums*, and others.

WM. FALCONER.

ACINETA HUMBOLDTI.

## ACACIAS.

Why have the numerous species of this extremely showy family almost completely gone out of cultivation? During the early spring months their flower-laden branches used to enliven our greenhouses and conservatories, and what, let me ask, have we got in their places? Absolutely nothing. They maintained their ground longest at Kew, but even there most of the grand old specimens have disappeared, and their gay flowers no longer serve to make lively the dull days during winter and early spring. *Acacia Riceana*, a species recently brought forward as a new plant, was amongst the last of the Kew collection that disappeared. I do heartily trust that at least all the more beautiful species of this family will soon again occupy the position which they once held in our greenhouses.

The Australian members of this genus may be easily raised either from seeds or cuttings; they should be potted in a mixture of peat, loam, and sand, in the proportion of two parts each of the two first, and one of the last. In summer, after their growth is made, they may be set in the open air, fully exposed to the sun, but at the same time they must be well supplied with water, and never allowed to suffer from drought. Some of the species have a tendency to make long straight shoots; these, therefore, should be selected for training upon rafters or pillars, on which they thrive well and form splendid ornaments in spring, whilst the more shrubby kinds will be equally at home in pots in the form of bushes. When in flower they may be used to decorate corridors or halls, but I cannot recommend their introduction into the drawing-room, except as cut-flowers, on account of a disagreeable odour which their roots emit, and which is very perceptible when confined indoors. As to colour, they are with few exceptions yellow, of some shade or other; I shall, therefore, merely give the name of a few species, which will amply repay anyone for bestowing on them a little attention, noting at the same time the periods at which they bloom.

A. Drummondii, April to June.	A. taxifolia, April and May.
A. Riceana, March to June.	A. diffusa, March and April.
A. pulchella, May and June.	A. argyrophylla, March and April.

## GARDENIA FORTUNEL.

Of the many fine plants for which we are indebted to Mr. Fortune, we think that, tested by a jury of ladies, this would be pronounced the finest; for to the purity and doubleness of the white *Camellia* this plant adds the delicious aroma for which the whole tribe of *Gardenias* is so much prized. The market growers who cultivate the *Gardenia* by the thousand for the supply of the bouquet makers of Covent Garden grow them principally by means of the heat of fermenting materials. The general plan is to have a pit filled with spent Hops from the brewer's, or tan, for bottom heat, and then linings of stable manure around the sides of the pit. The plants in the growing season delight in a brisk, moist temperature, and that of a good hot-bed or pit is very congenial to them; but to mature the wood and set the flower buds it is necessary that they be exposed to a drier atmosphere and a free circulation of air. Cuttings of the *Gardenia* strike with the utmost freedom in a close, moist temperature, with some bottom heat. Though heat from fermenting material is the most suitable for the cultivation of this tribe of plants, it must not be supposed that they will not grow in an ordinary plant stove. Plants so treated we now have of *G. Fortunei*, *G. florida*, and *G. florida intermedia* finely set with bloom buds. During the growing season they were placed in the closest part of the stove, and were well supplied with manure water. When the growth was complete and the flower buds forming, they were exposed to full air, and for some months past they have been in a cool house with the *Camellias*. When we want bloom they will be removed to a forcing house, and there remain to make their growth. As a forcing plant, to come into bloom in March and afterwards, we know nothing so valuable as the *Gardenia*. It is a universal favourite with all who know it, and will ever remain so. The only drawback is that insect pests of every kind have a great affection for it. Mealy bug, white and brown scale, thrips, and red spider

each grow fat and multiply upon it. The best remedy for these pests is to lay the plants upon their sides, and then syringe them when in a dormant state with water heated to 120°; then follow with a dressing of Abyssinian mixture of full strength, and the visitation will be subdued, if not eradicated. The kind mostly grown for flower-market purposes is *G. radicans*. It is a dwarf, free blooming species, and, carefully managed, flowers most profusely. A.

## NEW SUCCULENTS.

The following are in Mr. Peacock's collection at Hammersmith, and to all of them first-class certificates were awarded the other day by the Royal Horticultural Society:—

**Mammillaria Peacockii.**—This curious plant looks not unlike a ball of grey worsted, its spines entirely hiding the stem. It comes from Mexico.

**Pilocereus Peacockii.**—So named in honour of Mr. Peacock by M. Roezl, who introduced it. It is quite a distinct species, clothed with cream-coloured hairs, and spines of the same colour 1 inch long.

**P. Hoppenstedta.**—This is another new species, introduced by M. Roezl. It has sharp angles, and is furnished with brown and white spines, 2 inches long, forming at the apex a dense mass.

**Yucca Eylesii.**—A noble plant of Palm-like appearance, having a stem 8 feet high, crowned with a mass of foliage 2 feet 3 inches long, without spines or filaments. It comes from Mexico.

**Agave Corderoyi.**—This is one of Mr. Besserer's introductions. Its leaves are strap-shaped, a pale green in colour, and from 1½ foot to 2 feet long, and 1½ inch broad. Its spines are black, small, terminal, and an inch in length. The plant itself is compact, semicaulescent at the base; the leaves are flat, but those on the upper part are canaliculate. In short, this *Agave* seems to be quite distinct from any other belonging to that genus, and it does not appear to grow to a very large size. It has been named *Corderoyi*, in honour of Justus Corderoy, of Bleubury, Berks, by M. L. de Smit, of Ghent.

**Sparmannia africana.**—This is one of the many good old plants we seldom meet with now, though it is a plant of the easiest possible culture, and produces an abundance of showy white flowers during the winter and spring months, a period when flowers are most valued for bouquets and dinner-table decoration. Introduced from the Cape of Good Hope in 1790, it has remained in our gardens here and there, but it is not so well known and appreciated as it deserves, if its floriferous habit and general usefulness are considered. After its flowering season is over, it may be pruned back quite close, and grown on during the summer months for blooming again the following winter. It will grow in an ordinary greenhouse, or may be introduced with advantage into an intermediate house or plant stove. If grown on during the summer in a warm temperature it will bloom earlier in the winter months, while plants grown in a cooler temperature will come in to succeed the stove-grown ones. It is very easily propagated by cuttings, which may now be inserted, four or five in a 32-sized pot, and, if allowed to remain in the cutting pots and grown on, will make nice little plants for conservatory decoration the following winter. This plant is by some discarded as a shy bloomer, but I have invariably found that, if pruned close back and grown on freely during the summer, as recommended, an abundance of bloom has been the result. From a botanical point of view the plant is remarkable as having irritable stamens; more especially is this peculiarity shown during bright sunshine, the stamens gradually diverging with great regularity on their being touched with the finger or any other body.—A. P.

**Eucharis amazonica.**—Nothing can exceed this in beauty as a winter-flowering plant. We have now in the gardens at Rendlesham Hall fine plants of it in 10-inch pots, with seventy-two flower spikes on them.—J. MILL.

**Palm Seeds.**—How am I to treat seeds of *Seafarbia elegans* gathered in 1871?—BREA. [Seeds of *Seafarbia elegans* may be sown at any time. If as old as you say, they should be tested; if the embryo is plump all is right; plunge the pots containing them in a bottom heat of 50°.—J. C.]

## THE FRUIT GARDEN.

### DESSERT ORANGE CULTURE.

BY THOMAS RIVERS, SAWBRIDGEWORTH.

IN the diary of that "fine old English gentleman," John Evelyn, may be found an intimation to the effect that he had eaten as good "China Oranges" plucked from his own trees as he ever wished to eat. In those days dessert Oranges were, it seems, called "China Oranges." Although Oranges were cultivated in France long before Evelyn's time, yet they were considered merely ornamental appendages to palaces and mansions; no thought seems to have been turned to them, so as to consider them fruit trees; and even Evelyn, with his remarkable horticultural sagacity, does not mention that he had ranked Orange trees among fruit trees; for in his "Kalendarium Hortense," when he mentions for every month "fruits in prime and yet lasting," no mention is made of Oranges; it would seem, therefore, that his gathering of Oranges fit to eat was an accidental occurrence, and we are led to suppose from the silence of gardeners for nearly two hundred years as to their culture, that the Orange-eating world has felt perfectly satisfied with imported Oranges, brought quickly by fast-sailing vessels; still, the difference between Oranges freshly gathered from the trees, and the very finest imported, is most remarkable; there is a crispness and fine aroma in Oranges freshly gathered difficult to realise, unless they are promptly compared with imported fruit; they are indeed a luxury, and, as such, will be cultivated ere long in every good garden.

The houses best adapted for their cultivation are the large span-roofed, 24 feet wide, 6 feet high at each side, and 15 feet high in the centre. A house of this size will require eight four-inch hot-water pipes, four on each side; artificial heat is required all the year to ripen Oranges in one season perfectly. A smaller span-roofed house, 5½ feet high at each side, and 12 feet high in the centre, heated by four four-inch hot-water pipes, two on each side, is almost as eligible for Orange culture as one even of the larger size. A house of these dimensions, with a central path, and a border on each side planted with Orange trees, would form a pleasant and productive Orange garden; but to form an Orange grove, so as to have trees of fine growth, and to give abundant crops, the larger house must be resorted to. From the experience I have gained, I firmly believe that no conservatory, no Orchid house, no greenhouse, is half so beautiful or interesting as an Orange-house constructed on the principles I now advocate, and provided with fixed roofs, rafters 24 inches apart, glazed with a large piece of glass, and admitting abundance of light; so that in December, when the trees are covered with their golden fruit, and many of them showing their snowy-white perfumed flowers, the scene is, indeed, enchanting, and is enhanced by the agreeable temperature, which need not be higher than from 50° to 60° (10° to 15° Cent.) in cloudy weather. It is not fierce heat in winter that ripening Oranges require, but an even, agreeable temperature, such as is experienced in the Azores during that season of the year. The houses above mentioned should have side ventilation, as in orchard-houses, viz., an opening in each side of the large house 2 feet wide, for the smaller houses 1 foot wide; these openings should be in the centre of each side, and shutters of wood or sashes employed to close them, the latter, of course, being the most agreeable. In houses thus treated, Orange trees may be cultivated in pots or tubs, or planted in the borders. There is no doubt that more rapid growth would take place if such borders were heated by having hot-water pipes placed 2 feet under the surface; but from recent experience I am inclined to think this is not absolutely necessary, for if the borders are raised 18 inches above the surface, they would have sufficient heat from the atmosphere of the house, and their temperature would be quite equal to sustain the trees in health.

The cultivation of dessert Orange trees in pots or tubs is very simple; the compost they require consists of equal parts of peat, loam, and manure thoroughly decomposed; the two former should not be sifted, but chopped up with the pieces of turf and roots, so as to form a rough compost. The trees will grow in this freely, and bear abundantly; but they should have gentle, constant, root heat; this is best

given by enclosing hot-water pipes in a shallow chamber of bricks, and placing the pots on a flooring of slates or tiles forming the roof of the chamber. The compost for the borders in which Orange trees are to be planted should consist of turfy loam two parts, and equal parts of thoroughly decomposed manure and leaf-mould. After planting, the borders should be trodden down firmly, as Orange trees seem to flourish best in firm loamy soils. In the Orange gardens of Nervi, where Orange trees are, or used to be, so largely grown for exportation, and imported by the London dealers in oil, &c., the soil is a tenacious yellow loam. The best form of tree for an Orange garden under glass is the round-headed, a form which it seems to take naturally; for if it is endeavoured to be cultivated as a pyramid, which would seem desirable, its lower branches soon become weakly and unhealthy. If trees with stems 2 or 3 feet in height are planted, the lower branches may be gradually removed till a clear stem of 5 feet in height is formed, and this height will be found sufficient. They may be planted from 5 or 6 to 7 feet apart, according to the size of the house, and the room which can be afforded for each tree. It must not be forgotten that in small houses the heads of the trees may be kept in a compact state by summer pinching, and in large houses be allowed a greater freedom of growth, so that the owner of an Orange garden in England may sit under the shade of his Orange trees. No one but an amateur of gardening can imagine the pure, quiet pleasure of taking a morning walk in the Orange house, during the above-mentioned dreary months, and plucking from the trees Oranges fully ripe. I have had much experience in the culture, and I may add, in the eating of fruit; but I can say with a firm conviction that I have never enjoyed any kind of fruit so much, as I have Oranges of my own plucking in winter.

#### SORTS.

There are but few kinds yet known of really fine dessert Oranges; the amateur who wishes to plant an Orange garden to supply his dessert, must not think of planting the most numerous varieties of the genus *Citrus* grown by Italian and French cultivators; they are mostly what are called fancy sorts, and are more prized for their foliage and flowers than for their fruit. One of the most charming and prolific of dessert Oranges is the Tangerine; the tree has small leaves, and seldom attains a height of more than 7 feet, even in North Africa. Its most valuable quality is its early ripening, so that in October, just as the late Peaches and other soft fruits are over, this luscious little fruit is ready for the dessert; and when freshly gathered no fruit can be more gratifying or delightful, as its aroma is so delicious, and its juice so abundant; in this respect offering a pleasing contrast to those imported from Lisbon in November and December, the flesh of which is generally shrunk from the rind, instead of being ready to burst, as is the case with those plucked from the tree. They should, in common with all home-grown Oranges, be placed on the table with some leaves adhering to their stalks, thus showing that they have not made a voyage. Among full-sized Oranges the Maltese Blood takes the first rank; when quite fresh from the tree it differs much from those imported, although the voyage as now made by steamers is of short duration. I was not so fully aware of this till early in January, 1866, when I was able to compare some fine imported fruit with some gathered from my trees. I found the former, although rich and juicy, yet flat in flavour compared with those freshly gathered; they lacked the crispness and aroma which were most agreeable in the latter. The great advantage in planting this sort is its tendency to bear fine fruit while the trees are young; they are indeed so prolific that trees of only 2 feet in height have here borne nice crops of fruit. Some varieties, quite equal to the foregoing in quality, but without the red flesh, so peculiar to these "Blood Oranges," have been imported from the Azores, the paradise of Orange trees. One of the most desirable sorts is called simply the St. Michael's Orange. This kind has a thin rind, is very juicy, and bears abundantly, even while the trees are young. In the Orange house, these will ripen towards the end of December, and throughout January and February, in common with the Maltese blood Oranges. In addition to the three leading varieties I have mentioned, there are several kinds which will, doubtless, prove interesting and valuable. It is not to be ex-

pected that so much variation in flavour, as in the Pear, for instance, can be met with in Oranges. I believe, however, that when our Orange palates are educated we shall find many delicate distinctions in the flavour of Oranges. As far as I have gone I have found the Mandarin Orange larger and more flat in shape than the Tangierine, and not so good as that sort. The Embiguo, the Egg, the Silver Orange, the Botelha, the White Orange, and some others, all varieties from the Azores, are of various degrees of excellence, and are all worthy of a place in an English Orange garden. It may be added that the Lemon, more particularly the Imperial Lemon, is well worthy of a place in the Orange garden, as is also the small Lime, which is a concentration of acidity.

The Oranges this season (1872) at Sawbridgeworth are particularly fine and rich; there is also an abundant crop, the sight of which is most gratifying.

#### EARLY FRUITING OF PINES.

I AGREE in the main with the remarks of your correspondent Mr. J. Groom (page 521, vol. ii.), but I must state that the fruiting of Pines, yes, and the ripening of them too, within twelve months of their being taken from the parent plant, is not an isolated circumstance, but an established fact repeatedly accomplished. Special means must, however, be used to attain this end. The suckers, before being taken from the parent plant, must be in every respect strong and well matured. They must be potted in 7 or 8-inch pots containing sound friable turf, and subjected to a bottom heat of from 85° to 90°, with a proportionally cool atmosphere; they must also be slightly shaded for a few days from bright sunshine. They quickly become established and should be immediately transferred to their fruiting pots and encouraged by a genial atmosphere, as it is important they should have as little check as possible. If they do not "show" at the expected time, both temperatures just given may be lowered and water withheld for a week or two, care being taken not to carry out these restrictive measures so as to materially affect the health of the plant, and by again resorting to a suitable temperature fruiting is almost certain to be induced. Much the same measures as these used to be carried out in the Hamiltonian system of Pine growing, except that the old plants were planted out and two suckers generally left upon each, instead of being detached, and they were encouraged by earthing up after the fruit was cut; thus they fruited and ripened, as a rule, within twelve months from the time the first fruit was cut. Such extreme precocity with regard to the fruiting of the Pine-apple is not, however, to be attained by any other means than by extra strength and maturity of the suckers. And if the latter can be nursed for a couple of months upon the old stools after the fruit is cut, there is a decided gain. In the case of vigorous young plants, when the suckers have been confined to one or two upon each plant, it is astonishing the progress made in a genial atmosphere.

I had a bed of Pines that fruited in summer and ripened fruit of excellent quality, the whole being ripened and cut within sixteen months of the time when the suckers were put in; and I have had also smooth Cayennes and Queens which ripened their fruit within the twelve months; several of the Cayennes weighing over nine pounds.

An important point in this matter is that young Pines invariably produce the finest and most perfect fruit. I look upon it as a general rule, that Pines should be induced to start into fruit from twelve to eighteen months from the time the suckers are put in. If this is accomplished there need be no cause for complaint. When they exceed that period without showing, however strong in appearance the plants may appear, they rarely produce fine fruit, and it is better to adopt measures to induce fruitfulness by repotting into fresh soil than to leave them longer under the same conditions.

Witley Court, Worcester-shire.

GEO. WESTLAND.

#### NOTES AND QUESTIONS ON THE FRUIT GARDEN.

**Oranges.**—The Orange trade of London is assuming vast proportions. The following are the estimated quantities imported into London last season from the several places of growth: Valencia, 181,000 boxes; St. Michael's, 120,000; Lisbon, 65,000; Sicily, 27,000; Terceira, 28,000; Simla, 27,000; and other districts, 12,000—in all 553,000 boxes. The contents of a box average 500 Oranges; consequently the total supply of the metropolis was 225 millions.

**Imported Bananas.**—Bananas are about the costliest green fruit now imported. They are brought from the West Indies in vessels specially fitted for their transport. Bunches of from 50 lbs. to 100 lbs., as taken from the tree, are suspended on hooks in the hold or in cabins allotted to their conveyance. They arrive quite fresh-looking at Covent Garden, and will keep for weeks if guarded against pressure. Ten years ago, when first introduced, they cost the dealers about ten shillings a bunch, but the same quantity now costs twenty shillings. They are retailed by the dozen at from three to five shillings.

#### THE HOLME, REGENT'S PARK.

WE give this week a plan of one of the prettiest small gardens with which we are acquainted. It lies between the ornamental water in the Regent's Park and the Inner Circle. The views from the lawn and the house are so managed that the water and park scenery seem part of the place, and the views are charming. The place illustrates some good points in garden design. The kitchen garden frames, houses, &c., are, for example, well concealed. The small flower garden, the effect of which is very simple and pretty in spring or summer, is also tastefully cut off, and the lawn on the lake side of the house is free and open, permitting of easy movement, affording pretty views to many parts of the park, while it is gracefully adorned with trees and shrubs.

The mansion is situated in about the centre of the grounds, on a slight eminence, and commands a very pretty view of the Park, the hills of Hampstead and Highgate, and the surrounding country. Adjoining the south wing of the house there is a neat metal conservatory. Leaving the flower garden, the next feature of interest is the rock garden, which, though very small, is so admirably intersected by walks and high banks covered with various rock plants (among which are some very choice Ferns), as to lead a stranger to imagine it is of considerable extent. The rock-work is the most natural of any we know in the neighbourhood of London, and with its Brambles in wild luxuriance, and various wild plants, one might almost consider it as in the Peak of Derbyshire, or among natural rock scenery. From the rock-work, we proceed through a stalactite cavern, with its coloured light and waterfall, until we come to a door glazed with pale lemon-coloured glass, through which we perceive the Orchid-house, which is also a rock-work arrangement, and which one might almost fancy to be a natural cavern, the top of which had been taken off, and a glass roof substituted. Some of the Orchids are growing beautifully on the rock-work, and the Ferns are quite at home in such a situation. This garden is at all times well kept, and in very neat condition, under the management of Mr. Stone, the rocky fernery being particularly chaste and natural.

#### THE FLOWER GARDEN.

##### THE MIXED SHRUBBERY BORDER.

No practice is more general, or more in accordance with ancient custom, than that of digging shrubbery borders, and there is none in the whole course of gardening more profitless or worse. When winter is once come, almost every gardener, although animated with the best intentions, simply prepares to make war upon the roots of everything in his shrubbery border. The generally accepted practice is to trim, and often to mutilate, the shrubs, and to dig all over the surface that must be full of feeding roots. Delicate half-rooted shrubs are often disturbed; herbaceous plants, if at all delicate and not easily recognised, are destroyed; bulbs are often displaced and injured; and a sparse depopulated aspect is given to the margins, while the only "improvement" that is effected by the process is the annual darkening of the surface by the upturned earth. Walk through gardens in winter and spring, and observe the borders round masses of shrubs, choice and otherwise. Instead of finding the earth covered, or nearly covered, with vegetation close to the margin, and each individual developed into something like a respectable specimen of its kind, we find a spread of recently dug ground, and the plants upon it with an air of having recently suffered from a whirlwind, or something or other that necessitated the removal of mutilated branches. Rough-pruners precede the diggers, and bravely trim in the shrubs for them, so that nothing may be in the way; and then come the delvers, who sweep along from margin to margin, plunging deeply round and about plants, shrubs, or trees. The first shower that occurs after this digging exposes a whole network of torn-up roots. There is no relief to the spectacle; the same thing occurs everywhere—in a London botanic garden as well as in our large West-end parks; and year after year the process is repeated. While such is the case, it will be impossible to have an agreeable or interesting margin to a shrubbery; albeit the

PLAN OF THE HOLME GARDENS, REGENT'S PARK.

importance of the edge, as compared to the hidden parts, is pretty much as that of the face to the back of a mirror. Of course all the labour required to produce this unhappy result is worse than thrown away, as the shrubberies would do better if left alone, and merely surface-cleaned now and then. By utilising the power thus wasted, we might highly beautify the positions now so very objectionable.

If we resolve that no annual manuring or digging is to be permitted, nobody will grudge a thorough preparation at first. The planting should be so arranged as to defeat the digger. To graduate the vegetation from the taller subjects behind to the very margin of the grass is of much importance, and this can only be done by the greater use of permanent evergreen and very dwarf subjects. Happily, there are quite enough of these to be had suitable for every soil. On light, moist, peaty, or sandy soils, where such things as the sweet-scented *Daphne Cneorum* would spread forth their dwarf cushions, a better result would ensue than, say on a stiff clay; but for every position suitable plants might be found. Look, for example, at what we could do with the dwarf green *Iberises*, *Helianthemums*, *Aubrietias*, *Arabises*, *Alyssums*, dwarf shrubs, and little conifers like the creeping Cedar (*Juniperus squamata*), and the tamarix-leaved Juniper! All these are green, and would spread out into dense wide cushions, covering the margin, rising but little above the grass, and helping to cut off the formal line which usually divides margin and border. Behind them we might use very dwarf shrubs, deciduous or evergreen, in endless variety; and of course the margin should be varied also.

In one spot we might have a wide-spreading tuft of the prostrate Savin pushing its graceful evergreen branchlets out over the grass; in another the dwarf little *Cotoneasters* might be allowed to form the front rank, relieved in their turn by pegged-down Roses; and so on without end. Herbaceous plants, that die down in winter and leave the ground bare afterwards, should not be assigned any important position near the front. Evergreen Alpine plants and shrubs are perfectly suitable. But the true herbaceous type, and the larger bulbs, like Lilies, should be "stolen in" between spreading shrubs rather than allowed to monopolise the ground. By so placing them, we should not only secure a far more satisfactory general effect, but highly improve the aspect of the herbaceous plants themselves. The head of a white Lily, seen peeping up between shrubs of fresh and glistening green, is infinitely more attractive than when forming one of a large batch of its own or allied kinds, or associated with a mass of herbaceous plants. Of course, to carry out such planting properly, a little more time at first and a great deal more taste than are now employed would be required; but what a difference in the result! In the kind of borders I advocate, nearly all the trouble would be over with the first planting, and labour and skill could be successively devoted to other parts of the place. All the covered borders would require would be an occasional weeding or thinning, &c., and perhaps, in the case of the more select spots, a little top-dressing with fine soil. Here and there, between and amongst the plants, such things as *Forget-me-nots* and *Violets*, *Snowdrops* and *Primroses*, might be scattered about, so as to lend the borders a floral interest, even at the duller seasons; and thus we should be delivered from digging and dreariness, and see our ugly borders alive with exquisite plants.

Assuming that one did not sufficiently esteem hardy flowers to go even to the trouble of adapting the margin of a shrubbery to them, it may not be amiss to point out that the beds of *Rhododendrons* and American plants generally offer the finest positions that can be desired for the making of the most charming and satisfactory kind of mixed borders. The culture of *Rhododendrons* has for many years been so popular in this country that there are few places that do not possess beds or masses of them, or in which fertile masses of peaty soil have not been gathered for their reception. The *Rhododendron* bush, however fine in flower, has at all times a flattish, formal outline, and this is often disagreeably apparent where large masses are planted, as is now the custom in many places. The soil suited to the *Rhododendron* is also perfectly suited to the most beautiful and fastidious of all fine perennials. The

bold and tall heads of Lilies standing above the flat green of the *Rhododendrons* in summer, sometimes, as in *L. tigrinum Fortunei* and *L. superbum*, in magnificent candelabra-like heads, are the very things to relieve these masses in the most effective way. Then again, the Lilies themselves will be seen to much greater advantage; the bases of their stems, being hidden by their surroundings when withering, will not be an eyesore, as they often are when in a border, so that an impatient gardener might want to cut them down before their time, or have something else in their place. The very open spaces which long remain between *Rhododendrons*, &c., in consequence of their somewhat compact and slow-growing habit, encourage the kind of arrangement suggested. It would be desirable to treat various classes of plants in this way, as, for instance, the Lilies, the *Gladioli*, *Sparaxis pulcherrima*, *Pritomas*, *Crococsmia aurea*, &c., none of which need be disturbed after being planted, though tall and graceful subjects are undoubtedly best suited for it. But even round the edge such comparatively dwarf subjects as the Solomon's Seal and the beautiful *Lilium longiflorum* might be placed with the happiest results. In the case of some of the American Lilies, like *L. superbum*, this plan is not merely a good one for growing the plants, but it is better than any hitherto pursued with them, the peat soil and the partial shelter enabling them to attain their true dimensions and highest beauty, whereas as commonly grown they are starved, and rarely bloom. Another advantage of this mode is the succession of bloom from the same surface. As a rule, once the blush of early summer bloom has passed from the American plants, they present an uninviting surface for the season afterwards; whereas varied in the way described the beds would be most attractive at other seasons. R.

#### NOTES AND QUESTIONS ON THE FLOWER GARDEN.

**The Best Twelve Tea Roses.**—I shall be greatly obliged if you or any of your readers will name for me the best dozen kinds of Tea Roses.—R. [The following are the best, we think:—*Devoniensis*, *Maréchal Niel*, *Gloire de Dijon*, *Souvenir d'un Ami*, *Souvenir d'Elise*, *Madame Willermoz*, *Triomphe de Reines*, *Niphetos*, *Cécile Forestier*, *Madame Margottin*, *Belle Lyonnaise*, *Adam*.]

**Schizostylis coccinea.**—I can fully endorse all that has been said as to the value of this plant. I have cut flowers from it for more than a month, and shall still cut more. It is an excellent plant for cut flowers, as they come out so well and last so long in winter. With the addition of Christmas Roses, *Jasminum nudiflorum*, and *Garrya elliptica*, we can still get a good nosegay from the outside garden. But with all this in its favour, the *Schizostylis* is a very capricious plant. I have had it for many years, but, as a general rule, it is a very shy bloomer. Probably the wet summer has suited it well.—H. N. ELLCOMBE, *Bitton Vicarage*.

## THE KITCHEN GARDEN.

### PARIS MARKET VEGETABLES AND THEIR CULTURE.

BY A PARIS MARKET GARDENER.

(Continued from p. 555.)

#### LETTUCE.

RABELAIS, curé of Meudon, is said to have sent to the Cardinal d'Éstrées in 1540 seeds of the first Lettuces grown in France. The plant was at that time extensively grown and used as salad in Italy. The two principal kinds in cultivation are the Cabbage Lettuce and the Cos or Roman. Of the former the following varieties are grown:—The black, the Gotte, the George's, the Palatine, the red, the grey, the *de la Passion*, and the *laitue à couper*. Of the Cos there are three popular varieties, the green, the white, and the grey.

#### CABBAGE LETTUCES.

The black Lettuce or *Laitue Noir*, which is the earliest of the spring crops, and which derives its name from the colour of its seed, is sown about the end of September under cloches, from which the air is excluded. Successive sowings are made up to the 12th of October or later. The seedlings are transplanted under cloches, twenty or thirty plants to each cloche, on sloping beds facing the south and covered with a good layer of fine rotten manure. Three rows of cloches are placed on each bed, and the plants are pricked in with the finger. No air is given unless the weather is very mild, and the plants appear likely to run to seed. Air is admitted by raising one side of the cloche and resting it upon one of the notches in

the side of a prop similar to that used for the frames, except that the lower part is cut to a point and is driven into the ground. The seedlings are planted out in moderately warm beds which have been prepared in the beginning of November. Forty-five or forty-six plants are placed in each bed, and no other seed is sown amongst them. At the same time some good hot-beds for Carrots are prepared, in each of which from thirty to thirty-six Lettuces are planted quincunx-fashion. These plantings are continued from month to month up to the 1st of February, always in hot-beds under frames, with sowings of Carrots, Spinach, or Radishes. In January and February also three plants of Cabbage Lettuce and one of Roman Lettuce are planted under each cloche among sowings of Carrots. The varieties George's and Gotte are sown from the 4th to the 10th of October under cloches like the black Lettuce; they are transplanted in the same way, but they must have plenty of air. Lettuces grown in cool beds are planted out in December, thirty plants under each light, among sowings of Parsley, Sorrel, Parsnips, or dwarf Celery. Four Cauliflowers may be interplanted under each light in February. When there is no frost air should be given to Lettuces in cool beds. They need not be covered except during unusually severe frost, and those which have been planted out in January need not be covered at all. Before planting out, the sowings should be covered with a good layer of rotten manure, and manure should also be placed on the walks, so that the soil may not be too much trampled. If planted out under cloches, three or four plants to each cloche will be sufficient; there might be three Cabbage Lettuces and one Roman in the middle. There should be three rows of cloches thus furnished on each bed. The red, grey, and Palatine Lettuces are sown under cloches from the 16th to the 20th of October, and are transplanted like the others. They are planted out under cloches, or on sloping beds or open squares in March, among sowings of any kind. The plants are set quincunx fashion, at intervals of 10 or 12 inches from each other. In the open ground they are sown from the month of March till September. The variety called De Passion is not grown by market gardeners: it occupies the ground for too long a time. It may be sown in nursery beds from the 15th of August to the 15th of September, and planted out in November in a warm position. It is hardy and does not suffer from the frost; nevertheless, it is as well to cover it with mats or litter when the weather is very severe. The variety named *à couper* is sown broadcast, and rather thin among the rows of Cabbages, or in spaces in which Melons are to be grown in May. Later on, it is sown instead of Corn Salad among the white Onions. In the same way, about the end of August, may be sown black Lettuces, George's, and Gotte, which in the end of September are to be planted out under cloches, six plants to each cloche; or under frames, thirty-five or forty plants to each light. They may be gathered in November and December. They should be sheltered from the frost by covering the frames or cloches with mats.

#### ROMAN LETTUCCES.

Sowings of green Cos Lettuces commence from the 1st to the 10th of October, under cloches, and the seedlings are transplanted like those of other Lettuces, with this difference, that Cos Lettuces sown on hotbeds are transplanted at the rate of from seven to fourteen seedlings to each cloche. Cos Lettuces may also be sown under frames, but the cloches are more generally used. The operations commence in December. The dung-beds should be made rather warm, and beds of warm manure should form the walks. Only one plant should be placed under each cloche, and great care should be taken to guard against frost. In January and February this mode may be employed with greater safety. Three rows of cloches are placed on each bed, with a distance from each other of 2 or 3 inches. One green Cos Lettuce and three black-seeded ones may be placed under each cloche, with a sowing of Carrots; or one Cos Lettuce and a sowing of Radishes. No air should be given to Cos Lettuces thus planted. Cos Lettuces are planted in cold beds in the same way as George's Lettuces, and transplanted under cloches to the number of nineteen to twenty-four under each cloche. Sowings are made from the 4th to the 10th of October. The seedlings are transplanted

under frames, twenty to each light, in quincunx fashion, associated with sowings of any kind, and under each light four Cauliflowers may be interplanted. If cloches are used, three plants are placed under each cloche. The light-yellow (*blondes*) and grey Lettuces are sown under cloches from the 15th of October to the 1st of November, and are transplanted in the proportion of thirty to each cloche. In March they are planted out in the open squares. They may also be placed in the sloping beds, but the green Cos is preferable there, because it is earlier. Other sowings of *blond* and grey Roman Lettuces are made from the month of March up to August. Crops of black-seeded Lettuce are gathered in January, February, and March, and then come in successively the George's, the Gotte, and the De Passion, the red-seeded, the grey, and finally, in November and December, the black-seeded or the George's. The small *au contain* Lettuces may be gathered all the year round, being protected, of course, in winter by a covering of some kind. The earliest Cos Lettuces are gathered in January, February, and March; these are the green variety raised in hot-beds. After this time and throughout the whole summer successive crops may be gathered from cold beds. We may have them even in October and November by planting them under frames or cloches.

#### TREATMENT FOR ALL KINDS OF LETTUCCES DURING WINTER.

We have said that all kinds of Lettuces are sown and transplanted on sloping trenched beds, and under cloches. The black-seeded variety and the Cos, when grown in hotbeds, should get no air; but all the other kinds should have air given them, except in case of frost. The green Cos should be taken up in November, and planted deeply, to protect it from the frost. Before it is taken up, and after it is planted again, air should be given, otherwise it will contract the disease called the *meurier*, and perish. Twenty-four plants are set under each cloche; but if a second transplanting is made, with nineteen plants under each cloche, the plants will be much finer. In December a ridge of manure should be placed behind the sloping beds, which will shelter the upper row of cloches when the frost comes. When the cold is severe, the air must be excluded, and mats spread over them. Should the cold continue, and the temperature descend very low, dry manure should be placed between the cloches, and if the temperature sinks still lower, they should be entirely covered with it. As long as the sun is up, the top is left exposed, in order to admit light to the plant, but as soon as his rays cease to fall on the cloches, mats should be spread over them. This protecting manure is removed when the frosts disappear, but it is kept in heaps in the walks (*soutiers*) within reach for some time, to be reapplied in case of a return of frost. Sloping beds of 7 feet to 7½ feet wide will be found the most convenient in this kind of culture.

(To be continued.)

#### NOTES AND QUESTIONS ON THE KITCHEN GARDEN.

**Wintering Carrots.**—We take up and store Carrots in winter as a matter of course; but it should also be known that (in dry situations particularly) they may be left in the ground all winter, if protected in severe weather with dry leaves or Fern. Kept in this way Carrots are much better flavoured than when hoisted. In storing Carrots it is not an uncommon, though an ignorant practice, to stack them in large heaps, and the consequence is quick fermentation and destruction. They should be stored in thin ridges among dry soil or sand. A shed is the best place, and in this they should be kept as dry and as cool as possible.—J.S.

**The Egg Plant.**—This is a favourite vegetable in America, where it grows to a good size, and is cultivated much as the Vegetable Marrow is here, that is, it is raised in heat and grown in the open air. It might be worth trying here, even though a Cucumber frame should be needed to make it grow. The purple sort is the best for kitchen use. In cooking it, take a middle-sized fruit (about 4 or 5 inches across) and cut it in slices about a ¼ inch thick; lay them on a plate and sprinkle salt between each layer, then turn a plate above them and place a weight on the top, to draw out the juice. Then wipe each piece with a cloth, egg and bread-crumbs them, and fry them in boiling lard or good dripping, on both sides a light brown. A little Parsley may be fried along with them for garnishing. Serve hot.—M.W.

On one occasion the Bishop of B—, in Scotland, was entertaining his choir at his private residence. After dinner, cheese, and amongst other things, Lettuces followed, and the Bishop handed a dish of the latter to one of his young guests, who after looking at it some time said, "Na, na, my Lord, thank you; I like my Kail (Cabbage) boiled."

## THE GARDEN IN THE HOUSE.

### THE VARIEGATED JAVANESE SCREW PINE.

(PANDANUS JAVANICUS VARIEGATUS).

WHERE room can be afforded this is well worth cultivation. A finely grown specimen of it well furnished with its prettily variegated pendant leaves is highly attractive; but it should never be too much crowded, for if it cannot stand quite clear of other plants, half its beauty is lost, a remark which also holds good in reference to all plants of similar habit. Their greatest charm lies in their finely-arched drooping leaves, which, to be seen to advantage, must stand clear of everything near them. This Pandanus is very attractive, even in a small state, but it is only when it acquires a size of some 4 feet through, and as much high, that it is seen in proper character. It is of easy culture; a small healthy plant of it in, say a 6-inch pot, if potted in February or March, into a 10 or 12-inch pot, well drained, using good turfy loam, with the addition of one-sixth of clean sand, making the soil quite firm in potting, will make a nice half-specimen in a year. It requires ordinary stove treatment, with a night temperature of from 70° to 75° during the growing season, and a rise of 10° in the daytime. Keep the soil moderately moist, syringe

Variegated Screw Pine.

the plant in the afternoons, and keep it well elevated near the glass, in order to induce a short compact growth; shading very little, as when much shaded it does not come so finely variegated. It is not very liable to the attacks of insects, except scale or mealy bug, both of which must be kept down by a diligent use of the sponge and camel's-hair brush. In the winter keep the soil a little drier than in summer, and maintain a night temperature not lower than 60°. Small plants may be used for table decoration, or in a larger state for vases, but they must not be kept long out of heat, or they will suffer. Suckers taken off and inserted in small pots, using half sand and loam, and keeping them moderately close, soon root, after which they should be treated as recommended for larger plants.

T. BAINES.

**Helichrysum Buds.**—Wishing this year not to lose even the unexpanded buds of these "everlastings," some of them were brought into the dining-room. On removing them, I thought I perceived a partial separation of the petals, and it occurred to me that this must be due to the artificial temperature of the room. I immediately tested the matter by placing a number of buds before the fire, and as a result obtained as many full-blown flowers. Knowing, however, the tendency of the *Helichrysum* to close after it has been in bloom, I was not satisfied with the experiment until I had ascertained that a night's exposure in the coldest room of the house failed to cause them to close.

**Common Hart's-tongue.**—Of this Fern, which may be found on shady banks almost everywhere, I gathered some specimens the other day in the Isle of Wight. I potted them, watered them, and placed them in the window of my sitting-room, and now they are so interesting and beautiful that I would advise all who wish to have something green in their windows at this dull time of year, to uproot a plant or two of this Fern from the nearest hedgerow, and treat it as I have done.—R.

## PUBLIC GARDENS.

### THAMES SCENERY.

It is probable that when every place of any natural beauty in the neighbourhood of London has been made irretrievably ugly Londoners will wake to a sense of the advantages they have lost, and of their own folly in letting them slip so lightly. Every year sees the city grow larger. Even young men can remember when a good deal which could fairly be called country was within reach of an afternoon's walk. Now, nothing of the kind can be reached except by railway, and there is no saying how far it will soon be necessary to travel, even by railway, before feeling that London has been left behind. Still, here and there accident or care has defended some special spots against the irrepressible advance of brick and mortar. They, too, may any day share the fate of the rest, but as yet they are unharmed. It is for Londoners to see that they remain so. They had need to be active now if they would save Hampton Court from the ruin which has overtaken so much else along the river bank. The Chelsea Waterworks Company intend, it appears, to ask Parliament for powers to build reservoirs along the right bank of the Thames which will extend from the mouth of the river Mole to the Swan Inn. To discover what these reservoirs will be like, we need only go a mile lower down the stream and see how Kingston has been spoiled by a similar process. In the case of Hampton Court the destruction will be much more complete. At Kingston the spectator is on the same side of the river as the Waterworks, and though the foreground has been made hideous by their agency, the view of the woods on the other bank remains. But at Hampton Court, the spectator, standing at the river end of the terrace, looks across to a line of Willows and trees, and if this is displaced by a long embankment of earth or granite, one of the chief beauties of the Palace gardens will disappear, and an element of positive and obtrusive ugliness take its place. Fortunately the Chelsea Waterworks Company has to get fresh powers before anything can be done, but we know how bills of this sort are smuggled through Parliament when it is nobody's because it is everybody's business to oppose them. At this part of its course the Thames is not rich in landscape. After Twickenham is past there is scarcely anything that tempts the oarsman to linger until he comes to Thames Ditton, and above Hampton Court he must go nearly to Windsor before he meets with any second temptation. Above the tidal stream, therefore, the mile or so between Thames Ditton and Hampton Court is the one really beautiful reach within an easy distance of London—the solitary representative of the glories which come so thickly when Maidenhead Bridge is once past. If this is destroyed—and to embank one side of the river between these two points is to destroy it—the Thames above Teddington Lock will virtually be closed to Londoners who are not prepared to journey five-and-twenty miles in search of it.

### THE THAMES EMBANKMENT GARDENS.

THE following is part of a leading article in the *Building News*. We by no means agree with all the conclusions of the writer, but think it desirable, in the interest of public gardening, that intelligent criticism should have free play:—"The humours of a retired merchant who, at Peckham Rye, Camberwell, or Denmark Hill, plants his Cabbages, and sets up for a man of taste, do not concern the public. His house, land, and everything that is his, are his own to use at his pleasure. The Thames Embankment does not stand in a similar case. The Metropolitan Board of Works are trustees of the public, who pay the piper, and have a right to the full value of the money they pay. Can any one who has seen the so-called ornamental grounds call them worthy of the metropolis, or worth the money they cost? The great mistake in the treatment of the reclaimed ground lay in ignoring its surroundings. Manifestly on made ground, with the lines of buildings never to be entirely shut out, and the water-level at hand to tell the tale like a philosophical instrument, the devisers have proceeded as though they had to deal with a suburban plot on a hill-side. Artificial mounds have been put up, sinuosities of path have been affected, borders of flowers skirt shrubberies, difficulties have been created but not overcome; in short, it would not be easy to point to another work of public importance where the first principles of landscape gardening have been more persistently violated (always excepting the improvements in Hyde Park, in the neighbourhood of Albert Gate) than the ornamental ground between Villiers Street and Waterloo Bridge. The proper treatment of the ground is manifest. The boundary line separating the Embankment grounds from the slums of the Strand, including the arches of the Adelphi and ignoble outhouses of all kinds, should have a screen wall somewhat similar to that which screens the buildings in Whitehall Place.

All attempts at rural-landscape gardening should have been avoided, and the whole attention of the designer directed to urban embellishment. Rural landscape-gardening and urban embellishment are very different things. A central avenue of Plane trees, the only trees which thoroughly withstand the London smoke, terminated at the Charing Cross end by a handsome architectural entrance—the York Stairs' Gate, for example, now ignobly buried at the foot of Buckingham Street—would be infinitely preferable to the meaningless paths, leading from nowhere to no whither, which at present puzzle the public. A central basin of sufficient dimensions, or an architectural mound of masonry or terra-cotta to contain flowers, would be quite enough in the way of floriculture. The ground should be, in fact, treated as an arboretum, not as a parterre. In the neighbourhood of the Strand, few evergreens thrive. The Holly, almost the hardiest tree we have, exists but does not thrive. Neither Laurel, Bay, nor Aucuba flourishes; Ivy, if of the right sort (which that on the ground alluded to is not), does fairly; Box never comes to much, and the Coniferae are out of the question." [There is certainly nothing now seen on the Embankment more objectionable than an "architectural mound of masonry" would be.]

**Garden Clerk at Kew.**—Your correspondent (Mr. Handy) appears to think that a man under thirty might be found competent to fill this situation; but, possessing as I do an extensive knowledge of the sort of men to be found in the gardening world, and of the duties of the place in question, I still hold to the opinion I at first expressed, more especially as I know that he will have to undertake the supervision of men who have had time to get, and have got, "proper experience and knowledge of their business." A botanical garden is a place quite different from a gentleman's garden, and a man, though thoroughly acquainted with the latter, is lost as soon as he gets into a botanical garden. As to Napoleon's generals, what he wanted in them was chiefly what is termed "dash," and for that young men were the best; but a man to be a good botanical gardener must study long and diligently before he can be considered to be master of his work.—J. CROUCHER.

## WORK FOR THE WEEK. PRIVATE GARDENS.

**Flower Garden.**—The unusual mildness of the past month, and more especially of the past week, has caused the buds of many shrubs to swell in a very unseasonable way, thus rendering them liable to injury from succeeding hard frosts, should such occur. Grass lawns are as green as they commonly are in March. In the case of flower beds, the surface soil should be slightly loosened whenever the weather is dry, but not so deeply as to injure bulbs planted therein. Spring-flowering plants are growing wonderfully; and Pansies and Daisies (Henderson's new double white one) are affording a few flowers, whilst different kinds of Christmas Roses are quite gay in the borders, and on walls the naked-flowered Jasmine is covered with its pretty Primrose-like blossoms. Alterations of all kinds should now be pushed forward with vigour whilst the weather is favourable for outdoor work. Trees of all sorts may be transplanted, taking care to lift them with as good balls as possible. After planting they should be firmly staked, and a mulching of litter or leaves placed over their roots.

**Bedding Plants.**—If Pelargoniums are to be wintered successfully in frames, keep them dry; give just sufficient water to moisten the whole of the soil in the pot when the plants begin to flag, but not a drop sooner. Remove all decaying leaves and everything else likely to generate damp; keep the sashes drip-proof, and admit fresh air freely by tilting them up throughout the day in favourable weather, but let them be shut up at night. Pelargoniums wintered on the top or other shelves of little conservatories or greenhouses should also be kept nearly dry. Calceolarias in frames should not be exposed beyond tilting up the sashes a little in fine weather; and they should also be kept clear of decaying leaves. Stir the surface soil amongst plants of Golden Feverfew planted in frames. Heliotropes, Ageratums, and Verbenas are best wintered near the glass in a minimum temperature of about 40°; and Iresines, Alternantheras, and Coleuses should have positions where the temperature does not fall below 45°. Salvias, Lantanas, Gazanias, &c., may be safely subjected to less heat. All these, however, must be kept moderately dry, though not too much so. Echeverias, Kleinias, Sedums, Scempervivums, Mesembryanthemums, and other all but hard succulents, may safely be stored in double lines along the passages or on the shelves of greenhouses, or in frames—indeed, in any situation where they can be kept pretty dry, and have plenty of light and air. Roots of Dahlias, Cannas, Fuchsia fulgens, Erythras, &c.,

may be stored thickly together in dry cellars, and have a little moderately dry sand scattered over them.

**Conservatories.**—This is the best time for destroying mealy bug, red spider, green-fly, thrips, &c.; for if allowed to remain untouched until warm weather sets in their extirpation is effected with much more difficulty. Plants done flowering and whose foliage is not attractive enough to make them worth a place in the conservatory should be removed, and their places supplied from the forcing pit, or by a re-arrangement of the plants already in the house. Rhododendrons, Camellias, Acacias, Eugenias, Araucarias, and other evergreen plants, greenhouse Palms, and tree Ferns should be supplied with water as they require it, for at no period of the year will they submit with impunity to absolute drought. Nothing is so effective at present as the Rhododendron arboreum, plants of which are complete masses of brilliant scarlet; bright yellow is furnished by Coronillas, white by Camellias and Azaleas, and rosy-purple by Veronica imperialis. Use just sufficient fire-heat to keep out frost, and no more, and keep the atmosphere on the side of dryness, though paths and similar surfaces must be sprinkled now and then so as to maintain healthy action.

**Forcing House.**—Introduce in succession plants of Azaleas and Camellias, and syringe them slightly every day about noon. Place Callas in some warm corner, and if possible plunge them in a gentle bottom heat, giving them plenty of water and a little liquid manure occasionally. Keep them in 6-inch pots, which are large enough for them, and heed not the roots traversing the surface of the soil and down the sides of the pot until the flowers are formed, when all stray roots should be removed, the pots washed, and the plants gradually inured to less heat, finally consigning them to the conservatory. Lift Lilacs from the open ground with good roots, pot them, place them in heat, and syringe them twice a-day. If the purple kind is required to produce white flowers the plants must be forced in darkness. Ghent Azaleas, Weigelas, Jasminums, Kalmias, &c., are also now being forced. Place bulbs in heat as soon as they begin to push, and keep them there until they open their flowers. Spiraeas, Lily of the Valley, &c., should be kept in cold frames and introduced into heat as required.

**Stoves.**—Keep all evergreen plants growing gently. If they are kept dry for a time, and then more freely watered, they are sure to start prematurely into growth; but if kept uniformly moist, and at the same time drier than during their growing season, they go to rest, and start strongly when placed under the influence of increased temperature, light, and moisture. On open, dry days, ventilate a little, but not to such an extent as to cause draughts, or to lower the temperature, and shut up early. Start some of the earliest rested Gloxinias, also a few Caladiums. Start likewise a few early rested Begonias, young plants of Pentas carnea, Justicias, Gesneras, &c. Withhold water from the roots of Xanthosomas, Remusatias, Carenmas, Caladiums, herbaceous Begonias, Achimenes, Gloxinias, &c., so as to induce the foliage to die down, then place the pots on their sides until the roots are quite at rest. After a week or two turn the soil out of the pots, gather the roots together according to their kind, and store them thickly in pots of silver sand, being careful not to mix the different sorts. Roots of Remusatias and Carenmas winter very well without being turned out of their pots. Orchids may be placed on new blocks if necessary, or top-dressed, or repotted; be careful not to give them too much water, though to such as are growing and flowering, some must be applied.

## NURSERIES.

The busy season is at hand; consequently everything is being got ready for its approach. Peat is being got under cover or stacked out-of-doors, as are also loam, turf, leaf-mould, and sand. Pots are being washed, packing cases mended and new ones made, Willows cut and bundled, stakes renovated, and everything likely to be wanted in spring is being provided. The bulb trade is all but over for the season, and all hands are busy in the seed department. Cuttings of soft-wooded Heaths may yet be struck, as may also the young points of Boronias, Polygalas, and other hard-wooded greenhouse plants. Cut over a few Epacrises and place them in a moderate heat, to yield young shoots for cuttings. Separate and pot singly autumn-struck cuttings of Azaleas and Camellias. Place last autumn's struck Camellias, or those now sixteen months old, on a shelf near the glass, for grafting on in February and March. Repot some of the Heaths, in order that too much work may not occur at a time when it cannot be overcome. Introduce Pelargoniums, Verbenas, Lobelias, Tropaeolums, Lantanas, Colenses, Iresines, Alternantheras, Mesembryanthemum cordifolium, and similar plants into a brisk moist temperature, to start them into growth for cuttings. Keep roots of Cannas in pots dry by building the pots one above another in some dry cool place. Gradually dry off roots of Dahlia imperialis. Have a few

good strong roots of Yellow Queen, Queen of Primroses, or other strong growing sort ready to graft *D. imperialis* on in spring. Sow Palm seeds as soon as imported in pans or boxes of loamy soil; the boxes may be kept in any odd corner until the seeds have germinated, when they must be placed in a more prominent position. Rooted cuttings of *Stephanotis*, *Gardenias*, *Bouvardias*, *Aralias*, *Ixoras*, *Dracaenas*, *Dioffenbachias*, *Pavettas*, &c., must be potted singly, plunged in bottom heat, and kept under hand-lights or bell-glasses. Sow some *Anthurium* and *Aglaonema* seeds in some damp, spongy material, in heat. Gather the seeds of Aroids, *Anthurium*, *Aglaonemas*, *Ardiasias*, *Solanums*, &c., as soon as ripe. Sow some *Cyclamens* in an intermediate temperature, and keep the pans containing the seeds near the glass. Protect young flower-spikes of Orchids from cockroaches, by placing a little cotton around each, near its base; also poison these pests with phosphorus paste as you would rats, or trap them in little basins containing treacle and water. Good earthenware traps shaped like inverted basins are obtained at the potteries, so that when these depredators go to feed they drop in and get drowned. Sow Fern spores in rough peat, or in pans or pots, under bell-glasses, &c. Pot off the seedlings as they become fit for that operation, and also give older seedlings a shift.

#### MARKET GARDENS.

The dry, smny days of the past week have had a beneficial influence on market gardens. All hands have been set to work; those who cannot dig, trench, or shake up litter are placed with the women and boys to loosen the soil amongst Cabbages, Coleworts, Lettuces, Parsley, transplanted Onions, and similar crops. Get August-sown Onion-beds thoroughly cleaned; women with half-sieve baskets, to put the weeds in as picked, soon go over a large space on a dry day. When finished, slightly dig or loosen the alleys, and transplant Lettuces or Cabbages therein. Get all empty quarters manured and trenched, throwing the soil into ridges 2 feet apart. Vacant ground under fruit trees manure and dig for Radishes, and be sure to have the trees thinned or pruned before the ground is interfered with. Radish beds sown early in December should be uncovered every morning, replacing the litter at night. Keep a boy for each series of beds to frighten off birds. Warm borders which contained Tomatoes in summer are best adapted for winter-sown Radishes. Under fruit trees the beds receive a little shelter, whilst the little shade caused by the naked branches does no harm. Remove handlights and sashes from Cauliflowers, Lettuces, and Onions during the daytime, but replace them at night. The smallest amount of rain must be excluded from the Lettuces, as they are so apt to damp off if they become wet; therefore rather tilt up the sashes than altogether remove them. Thin and weed the plants, and stir the soil a little amongst them. Scatter some lime over all kinds of crops, more especially over those transplanted permanently, such as Cauliflowers under hand-lights. If ground is required, lift the Jerusalem Artichokes and store them; if land is not wanted, merely cut over the stalks and spread a layer of litter along the top of each drill. Dig the ground between lines of Rhubarb, and place a forkful of litter over each crown. Any Endive plants to spare plant in front of palings or walls. If the ground is required in which the general crop is growing lift the plants, tie a piece of matting around each, and lay them in thickly in a bed for a time. Protect them from severe weather by shaking some rough litter over them. Look over Mushroom beds twice a week if bearing well, if not, once will suffice. Examine Seakale beds producing Kale, and by means of the litter in the alleys and that covering the beds maintain an equable temperature. If necessary start two other beds by filling the alleys with fermenting manure, placing a covering of the same on the surface; over that put hoops and mats, to be covered with litter if wanted. Succession beds leave exposed. Treat Rhubarb in a similar way, but give the roots more room. Take the litter off sashes put over Mint frames, but replace it at night. Make another hotbed, lift another lot of roots, and start them to succeed those already in bearing.

#### PINE-APPLE CULTURE FOR JANUARY.

THE season has arrived when many plants have started, some starting, and others showing fruit. Great care and attention will be required in every stage of Pine-apple culture for the next six weeks, to be successful with the plants when in blossom, and with fruit that is up, to prevent any kind of abortion to a single pip, or the uneven swelling so easily produced at this season. There must be no check or hurry, either by attempting to drive or hurry on those fruits that are in any stage of swelling. Nothing but time, patience, and persevering attention will succeed in kindly starting, blooming, and swelling fruit to perfection while we have short and dark days. Patience must allow from fourteen to twenty-eight days longer for winter fruit, according to variety, to swell than those that will start

into fruit in February and March. If hurriedly forced, they will push up weak, long stalks, productive of small fruit, weak and irregular blossom, causing some pips to swell imperfectly, also causing uneven and abortive fruits, light in weight, and black inside, bearing overgrown crowns. From 65 to 70 should be maintained in the pits, with a kindly humidity during night, according to the light and sun by day, and the day interior atmosphere and humidity must be in proportion to the sun and light. For the withholding of water and humidity from fruit already finished swelling, and the placing of those almost coloured into a light dry situation, follow last month's instructions. For all growing succession plants maintain a kindly bottom and inside atmospheric heat, advancing it as the days lengthen, and light increases. Pot on plants in every stage that require it, never allowing their progress to be checked for want of pot-room at any season of the year.

JAMES BARNES.

#### THE GALE OF DECEMBER.

THIS is said to have been the most severe since 1703; but be that as it may, it is admitted to have been the strongest that has occurred within these last eight years, the pressure being at one time 33½ pounds to the square foot. Around London, glass houses were in some instances stripped. Many have foretold that my patent clip system of glazing without vertical sash-bars would not bear the wind power of a severe gale. I confess that as the sudden thuds of the gale shook the house in which I live, and the roof-tiles chattered, I slept nervously, but, in the case of 6,000 feet of glass fixed here, and upwards of 40,000 in different parts of the country, the only breakage has been one square here, and two at Brompton; thus, I think, very satisfactorily settling the matter of strength. Of course a house fully glazed is much safer than one partly so, but to show the immense resistance of Hartley's rolled plate glass, when properly fixed, I may relate the following fact. For some weeks past my men have been roofing a conservatory at Kidbrooke Lodge, Blackheath, the grounds being parallel with those of Morden College. The house is 51 feet long, 35 feet wide, 18 feet high at the sides, and 30 feet high to the top of the roof, the latter being a centre span with short lean-to sides. One side is fixed to the dwelling house, but the ends of the conservatory and the front are in masonry, so as to correspond with the residence. My centre roof is carried by columns 12 feet apart, connected by means of light, ornamental wrought-iron girders, but, instead of the usual heavy cast-iron columns, I have introduced the light and elegant "Ribbon Posts" of the Manchester Ribbon Telegraph Post Company. These, before they were fixed, I had tested to the necessary strength, but of course I had no idea that they would have been so soon subjected to the wind trial through which they have passed so triumphantly. Owing to defective brickwork, carried out locally, the wall was found, when my men wanted to attach their roof, to be in a falling condition, and had to be taken down. In this predicament the ribbon posts had to do double duty by carrying the iron work of the side roof as well as the centre. Add to this the fact that at the time of the gale the centre roof and the inner side roof were glazed with Hartley's rolled plate glass, make the further addition of wind pressure of 33½ pounds to the foot, and it will be seen that this roof, without ends or sides, and unsupported by any side wall, had to support the enormous pressure of nearly three tons to the square of 100 feet. I have much pleasure in being able to thus bear testimony to the strength of the Ribbon Post, for it is not only cheaper than cast-iron, but, being of light, trellis-like pattern, is for all conservatory and garden purposes immeasurably superior to it. Any one who may walk to the Morden College corner of Blackheath may see the conservatory roof alluded to, and test the accuracy of my statement. Trees close by were torn up by their roots, but from the partly glazed and wholly unprotected roof not a single square of glass was removed. I may add that in different places I have considerable stretches of wall-fruit preservers fixed. The squares in these are each 3 feet long, but in no case has one been broken.

W. P. AYRES.

**Fire at Mr. Messenger's Horticultural Works.**—We regret to learn that the works and machinery of Mr. Messenger, Horticultural Builder, Loughborough, have been destroyed by fire. Distressing as the effects of the fire have been, it is some consolation to learn that the workmen, whose chests of tools have been sacrificed, will not suffer much through loss of time, as temporary premises have already been taken to carry on the business, and the workshops will be immediately rebuilt. The principal loss is in the very large stock of prepared woodwork ready for erection, all being painted ready for sending off. Fortunately the bulk of Mr. Messenger's dry timber was stowed in other parts of the town, and thus saved from the general wreck.

## THE GARDEN.

"This is an art  
Which does mend nature: change it rather: but  
THE ART ITSELF IS NATURE."—*Shakespeare.*

### GROUND WORK.

THE importance of properly forming ground is very rarely sufficiently recognised. The other day we saw a croquet ground in the course of formation. To get the proper level, nearly 2 feet deep of soil had to be taken from the top part of the ground, to be filled in at the bottom. A person who understood the work would have filled in the loose soil in layers, 4 or 6 inches thick, and then rammed and consolidated it as the work proceeded. But as our learned amateur knew better than that, he wheeled the soil into its place to the full thickness, and having levelled it roughly, passed the garden roller over it several times, and having given the surface a smoothing with the rake proceeded to lay the turf. What will be the consequence? Just this. When the rain comes the turf in the soil will decay, and the whole will subside into a series of miniature pitfalls, rendering it useless as a croquet ground and necessitating the renewal of the work. Now, in the formation of a croquet, cricket, or bowling ground, or even the formation of a lawn or flower garden, it is necessary that the ground should be removed to a uniform depth, and if it is not it is indispensable that the soil in every hole should be properly rammed until it is brought to the proper surface level. In this manner the turf may have a smooth and proper foundation, and without that it is a waste of time to lay the turf at all. Soils differ much in the amount of compression which they require. Land, free from vegetable matter, will, after a good soaking rain, go together so closely as to need but little further compression, but fresh soil full of fibre will rot and settle for years if it is not thoroughly consolidated at the commencement of the work. Loamy soils can easily be properly handled when they are dry. If you attempt to ram them when they are wet you will form a plastic mass through which the rain will pass with difficulty, and hence the surface will always be damp and mossy, but if you ram such a soil when it is in a comparatively dry state, you may make it solid, and yet the interstices between the particles of soil will be sufficient to allow the surface water to escape with facility. In relation to new ground work a gentleman remarked the other day: "If that work had been done by the day I should have considered I was being most shamefully robbed, but now I see that the care you insist upon is necessary, and that the work is being executed in the best possible manner."

### VINE FAILURES.

NEARLY all gardeners of any extent of experience must have observed that certain vineries become suddenly famous for their crops of Grapes, and as suddenly lose the reputation thus obtained. That there is some sufficient cause or causes for this sudden wax and wane of fruitfulness, no sane man will deny, any more than he will the importance of a discovery of a remedy for the latter; and in order to arrive at some safe conclusions on the subject, I will proceed to make a diagnosis of a set of "worm-out Vines," and of the border they are planted in—I cannot say growing in, for the active roots have left it years ago. What, then, do I find? small, thin, flaccid foliage, the lateral growths getting annually smaller in wood and larger in pith; the foot-stalks of the bunches long and slender; the bunches composed one of half-matured, the other of shanked berries; the Vines very subject to attacks of red spider, or any other living pest that afflicts the Vine. If the atmosphere is kept moist, they throw out a great many air-roots. Altogether they are in a most unsatisfactory condition. Then what of the border? Dig down a foot deep in it and you find no young, active roots. The soil is more of the consistency of putty than anything else. It was rich when compounded, and is so much the worse now. In the process of its removal you come upon a fine large bare root, running as direct across it to the gravel walk beyond as the cable does across the Atlantic, and you are provoked to find that though there is not a living rootlet in the border that has been prepared with such care, there are abundance branching in all directions

among the broken bricks, stones, ashes, or gravel, as the case may be, that form the walk. My readers will probably remark, Then why not make the whole border of brickbats, stones, or gravel? I reply, better it were so than as matters but too frequently are found; at the same time I hold that a border properly made of good loam, with the addition of a few bones, a little horse-mannro, and, if the soil is heavy, some brick rubbish or burnt clay, or both, is far more likely to give good results than bricks, stones, or ashes. The reasons why the roots branch in all directions in the walk are that undoubted law of nature which provides many roots for a plant on poor soil as compared with those on rich, and the sweeter state—to use a technical term—of the material of which the walk is framed, as compared with the border, kept so by the air in the interstices amongst the stones. Others of the roots, as I have often found, have gone down into the miserably poor sand or gravel of the subsoil. They are anywhere, in fact, but where they were intended to be. Your neighbor plants a vinery, and he means to prevent the evil complained of. He bricks up the arches of his front wall to compel the roots to live at home till they occupy the inside border well, when he means to let them out; but they have their revenge, for they go first to the bricks, then trace them down to feel if they can get out underneath them. They fail, but they are away a yard from the surface, and when let out commence their march across the border at such a depth as deprives them of the genial influences of heat and air. So much for what we learn from an examination of the old Vines and their border. I will now, founding on much experience, suggest what the Vines may have been like when planted. They were probably what are styled in the advertisements of the present day, "fine strong planting canes," and to the comparatively inexperienced they appeared all they were represented, but a critical examination proved that they were as pithy as a rush. They had no well-plumped firm eyes, and when turned out of their pots it was discovered that they were grown in rich soil, half dung in fact, that they had been grown in bottom heat, and that many of the roots formed under such circumstances had decayed when exposed to a degree of cold that would do no injury to a properly grown Vine. They have been raised from eyes in small pots, where they remained till their tap-roots had made several journeys round the inside of the pot, when they were transferred to a 9 or 10-inch pot, to finish their growth and make several more coils round it. Another aspect of their treatment in early youth was that they were grown as near each other in a close moist atmosphere as beans in a field, their foliage never getting properly exposed to light and air. I by no means blame nurserymen for growing them thus, while the Vine-buying public expect to get "fine strong planting canes for 3s. 6d., and fine fruiting ditto at 5s." The thing is simply impossible at the present rate of labour and other appliances, including the space the Vines would require to grow them properly. This is a real case of sinking the ship to save a pennyworth of tar. I may here remark that I observe another delusion springing up at the present day about Vines for planting. I refer to advertisements setting forth that the subscribers can supply young Vines grown *without the aid of artificial heat*—as if this were likely to add to their value, when the reverse is the case. No Vine should be planted that is more than a year old from an eye, and to get such well grown and ripened in the climate of Britain requires more or less fire-heat. Such being the Vines, let us turn them out of their pots and proceed to plant them. The roots that have survived are twisted and entangled in all directions, and by the time leading roots are disengaged from the ball, there are no small laterals left on them; but they are a good length, and when spread out reach a long way across the border. While the stored-up sap in the Vine and roots lasts, progress in growth is made for a short time; and after a halt, young roots start from the points of the old extended roots, and, if the border has all been made up at once, get rapidly on with their journey across it. GARDENER.

**Another Poison.**—There has lately been discovered a poison called *Inea*, which is said to be more subtle than digitaline. The poison is obtained by pressure from the seeds of *Strophanthus hispidus*, an Apocynaceous plant, found in Gaboon; and from experiments made with samples of it, obtained from arrows, upon which the natives place it, as recorded in the *Lancet*, it appears that it acts more powerfully than digitaline or antiarine, and quickly paralyzes the heart. Three millegrammes kill a frog, a sparrow, or a dog, though the resistance of certain animals varies. A snail, for instance, requires five millegrammes; a mouse has withstood three millegrammes of the extract (obtained by macerating the seeds in alcohol), whilst this latter dose kills a dog 955 times heavier than the mouse. The heart comes to a complete standstill after a few irregular efforts.

## NOTES OF THE WEEK.

— MR. PENNY, formerly of St. Dunstan's, Regent's Park, has been appointed superintendent of the gardens of His Royal Highness the Prince of Wales at Sandringham. We also hear that Mr. Carmichael, who has, hitherto, been gardener there, has been appointed to succeed the late Mr. Donald at Hampton Court.

— AS we go to press the few old Thorns that for many years have been the only vegetable adornments of Leicester Square are being cut down, and a very high boarding erected, so that this too famous space will now be concealed by something scarcely less hideous than the surface of the square for the past year.

— WHILE in the west, the interior, and north of France the rain has been incessant, as in England, there is a perfect drought in that part on the coast of the Mediterranean. Thus at Montpellier, at the present time, they are likely to offer public prayers for rain, it being more than two months since they have had any.

— WE have just tasted some Easter Beurré Pears that have come all the way from California. They have travelled well, and may now be seen in some of the shop windows in Covent Garden. As regards their quality, it is decidedly superior to that of either English or French fruit of the same kind, the flavour being very fine and the flesh of a more even and tender texture than that of European-grown Pears.

— A YOUNG tree of the true Glastonbury Thorn, growing in Mr. Dean's seed grounds at Bedford, in an exposed situation, has already pushed shoots an inch in length from the extremities of the old wood, and bunches of flower-buds are visible. In a warm place, and during a mild winter, therefore, it would be no great wonder to see this Thorn in bloom on Old Christmas Day.—A.

— MR. PERRY informs us that various kinds of Narcissi are coming into flower in the open ground at Tottenham, where *Schizostylis coccinea*, and *Tritoma Uvaria* are still in considerable beauty. Snowdrops, too, are in flower in the same locality, as are also Primroses, including many double kinds, and the charming little yellow-eyed crimson *Primula altaica*. To these must also be added *Cyclamen vernum* and *Atkinsi*, *Potentillas*, *Genms*, *Tussilago fragrans*, *Lithospermum prostratum*, *Eranthis hyemalis*, and the pretty deep sky-blue flowered *Anemone blanda*.

— WE have just received the first number of the weekly issue of the *Gardeners' Record*, an Irish horticultural journal, which hitherto has only been published fortnightly. Its size has been increased, while its price has been reduced and a page or two devoted to agricultural matters has been added to it. An undertaking begun with so much spirit deserves hearty support, which we hope it will receive.

— THE tender little Cabbage Lettuces grown around Paris under the cloche, and also on gentle hot-beds, are now abundant in Covent Garden and in other English markets; they have been procurable since the beginning of December, and are now rapidly improving in quality.

— THE scarcity of fruit has led to the importation of Pears in the way of the Colmar type from the neighbourhood of Trieste.

— A POLITICAL Christmas tree was exhibited in Paris lately. It was a good-sized Fir from the Vosges mountains, torn up by the roots, with a quantity of the native soil of Alsace still clinging to it. Around this tree, richly laden with toys and bonbons, were congregated 2,000 children of Alsace and Lorraine exiles. M. Gambetta and several other deputies were present.

— THE owner of one of the most interesting bulb gardens in the neighbourhood of London writes to us concerning it as follows: "If there are sermons in stones and books in the running brooks, what must there be in flowers to a pent-up denizen of this great metropolis! Suppose the Thames Embankment, the borders in Hyde Park, and in Battersea Park were radiant now with something attractive, how tempting would it be to stroll out and inspect them on such a day as last Sunday—a day of sunshine and shower, when at one period we had April and at another December. During the April phase of the day I wandered to my bulb garden to see what sweet faces had unveiled themselves since my last visit. First on the list was *Crocus Imperati*, with its beautiful fawn-coloured black striped outer petals and inner purple petals, flaunting gaily in the sun with as much importance as the fair damsels who now display themselves in parti-coloured dresses; for verily, if this last development of dress was taken from nature, it must have been from *Crocus Imperati*, of which I send you a few flowers. My next attendant was *Crocus Sieberi*, a lovely purple. Having examined these, I turned to see what else there was to welcome me; and among other things there was a stray flower of the beautiful bright

yellow *Sternbergia lutea*. Further on the pretty winter Aconites, with their rich green foliage, were in full bloom. I next turned to my Cyclamen bed; there, notwithstanding the wetness of the season, *C. hederifolium gracum* was covering the ground with rich and massive foliage; not a yellow leaf or the slightest symptom of ill health was visible. Close by was *C. repandum*, producing a profusion of rich red flowers. Further on Hepaticas were unfolding their lovely blossoms, and *Narcissus maximus* was just raising its head from amidst the foliage, evidently requiring a week or two more of mild weather ere it will unfold its ample golden blossoms."

— EPIDENDRUM *erubescens* is now in flower at Ferniehurst. *Masdevallia tovarensis* is also in bloom at the same place, the plant bearing about a dozen of its snow-white flowers.—F. W. B.

— "I HAVE this day (January 3rd)," says Mr. Richard Nisbet, gardener at Aswarby Park, "gathered twelve fine half-blown Roses from a plant of *Devoniensis*, growing against a south wall. With us this old and favourite variety is always the first to open its buds and the last to go out of flower; it is, therefore, more esteemed than any other Rose grown in this part of Lincolnshire."

— THE Gurney family have made a most munificent offer to the inhabitants of West Ham and Stratford. It appears that those who are moving in the purchase of West Ham Park for a public recreation ground having put themselves in communication with the owners, have received an offer, in which the whole of the estate is offered to the parish for £25,000, and of this amount the Gurney family agree to contribute £10,000, allowing a large portion of the balance to remain on mortgage.

— MR. SAMUEL MORLEY, M.P., has forwarded a second donation of £50 to the Forest Fund, to assist the work of preservation of Epping Forest as an open space for the people of London. Prosecutions have also been instituted against people who have felled trees in, or otherwise damaged, the forest, which is hereafter to be kept intact.

— IN reference to the dispute between Mr. Ayrton and Dr. Hooker, we understand that a memorial to Mr. Gladstone has been prepared, which has already received the signature of almost every leading botanist in England unconnected with either Kew or the British Museum, setting forth the enormous gain which has accrued to science by the scientific work done at the gardens and herbarium at Kew under the management of the two Hookers.

— MR. BULL, of Chelsea, intends to offer £300 in silver cups for new plants during the next three years, as follows, viz., £100 each year; the value of £50 at the principal show to be held at Kensington in June (this season on the 4th, 5th, and 6th of that month), and the value of £50 at the society's provincial show, which takes place this year at Bath, on June the 24th to the 28th. The £50 will in each case be divided thus:—For private growers, first prize, silver cup value £12; second ditto, £8; third ditto, £5; for nurserymen, first prize, silver cup value £12; second ditto, £8; third ditto, £5. The competition to take place with twelve new plants of Mr. Bull's introduction, and sent out since the commencement of 1870 (this date being altered in the subsequent years to 1871 and 1872 respectively) as announced in his annual catalogues, which are to be the standard of reference as to the eligibility of particular plants.

— THE *Wilmington Commercial* prints some figures, claimed to be "substantially exact," regarding the Peach product of the Delaware Peninsula during the present year. The columns foot up to the grand total of 3,491,050 baskets, these representing only the actual shipments by rail and water, the 73,282 baskets used by canners, and the 10,000 baskets consumed in Wilmington. To these are to be added three important items, namely, the Peaches eaten on the farms, those distilled into brandy, and those sold for consumption in the several towns on the peninsula outside of Wilmington, all of which, it is calculated, will bring the total up to 3,600,000 baskets. The success of the Peach in this peninsula, girt by the Atlantic, Delaware, and Chesapeake Bay seems to point out that a marine climate is favourable to the Peach. We have noticed like evidence in England and Ireland.

— THE beautiful *Echmea Reginae*, which we noticed a few weeks back as being so fine in the Upper Holloway Nurseries, may still be seen there in superb condition. The continuity of beauty in the flower-spikes of this new Bromeliad greatly enhances its value; for although six weeks have elapsed since it expanded its flowers, it promises to continue in beauty for as long a period yet to come. The coloured leaves attached to the flower-spike constitute its greatest beauty, their colour being a brilliant magenta tinged with violet. The flowers themselves, which are produced in great conical heads, are tipped with violet blue. The foliage is robust and ornamental, and the plant is apparently a free grower.

## THE INDOOR GARDEN.

### DASYLIRION GLAUCUM.

This is usually met with, in nurseries, under the name of *Bonapartea glauca*. It is, however, not a *Bonapartea*, but apparently a *Dasylium*. It has a solid stem, like that of a *Draena*, thick and very short, the leaves, which are thick and glaucous, spreading out gracefully at the base in all directions, so as to form a round tuft. The leaves, whose edges are beset with short teeth, are hard and dry, especially at the extremities, and from their midst issues a stout flower-stem, which grows to a considerable height. At its base are little leaves, which gradually diminish, so that the higher ones are almost reduced to the size of scales, and soon dry up, as also happens to *Yuccas*. The flower-stem for at least two-thirds

*Dasylium glaucum.*

of its length is covered with clusters of flowers, which, though not very showy, are extremely interesting. Of the general appearance of the plant when in bloom, the accompanying woodcut will furnish a good idea.

### LINUM TRIGYNUM.

A LITTLE more than twelve months ago, in dark November, when the rain was falling in torrents, and the fog hung over the hills at midday almost as thick as at midnight, business called me into Derbyshire; and, as I make it a rule never to visit that county without calling at the "Palace," I made my way to Chatsworth, feeling convinced that, however much the storm might pelt without, I should, once under cover of the large conservatory and other glass houses, find that I had a taste of perpetual summer. I passed through the Orchid houses, glanced at the *Chrysanthemums*, admired the Palms and other foliage plants, and also the *Camellias*, and, arrived at the portal of the huge conservatory, the large folding doors were thrown open, and I stood amazed. On each side of the central carriage drive which divides this house stood magnificent

bushes of glowing gold, so much larger and finer than I had ever seen the plant before that I could not for the moment call to mind what it was. It was *Linum trigynum*. Now, if the reader will imagine trusses of from ten to thirty flowers, each as large as a half-crown piece, quite as flat and circular, and of brighter orange than the brightest *Calceolaria*, he will have some conception of what dense bushes, 4 to 6 feet high, and as much in diameter, must appear on such a day. These plants were growing in the open border of the house, and were bushes such as must give one an idea of what the plant must be in its native habitat. But it is not everyone who can grow this *Linum* in a conservatory border, as to bloom it thoroughly requires something more than the heat of a conservatory, and that cannot always be given. The mistake in its cultivation, especially in the nurseries, has been greenhouse treatment. The plant is a native of the East Indies and requires a warm temperature. The right treatment to follow is to take cuttings of either the young or ripened wood in February, and to strike them in gentle bottom heat. They strike with great freedom, so that from a single plant a large stock may soon be obtained. When rooted, pot them off singly, using a compost of turfy loam and leaf-mould, to which sand and charcoal broken small, to make it porous, may be added. Keep the plants in a moist atmosphere until they are established in the fresh pots, and then gradually inure them to more air. Once established, they will grow with great rapidity; but it is not worth while to stop them until the pots are well filled with roots; then dry them for a few days, and cut them boldly back to within 3 or 4 inches of the pot. This will cause them to break a number of shoots from the base, and from these sufficient may be selected to form the foundation of a plant. When the young shoots are about an inch long, repot the plants into pots two sizes larger than those they have been in, using the same compost, and adding a sprinkling of bone-dust to it. After this shift, if kept in a temperature of from 60° to 70°, freely syringed twice or thrice a day, and assisted, after the pots are full of roots, with weak liquid manure, they will grow with great rapidity, so as to form handsome specimens from 18 inches to 2 feet in diameter and the same in height. To this end they will require to be stopped a time or two during the season, but the last stopping should not be later than the end of July, or the young wood will not get sufficiently ripe to bloom. The greenhouse will be the best place during the autumn, and care must be taken to bring the plants gradually into a state of rest. If desired, they may receive a second shift, but this is not necessary unless very large plants are required. By the end of September some of them may be placed in a higher temperature, and they will begin to bloom in November, and continue to do so until the spring. The greatest drawback to this plant is its liability to the attacks of red spider. This pest grows fast upon it with singular rapidity, and therefore a sharp watch must be kept. The best plan to keep the spider in check is to lay the plants upon their sides, if they are in pots, at least once a week, and to syringe them thoroughly on the under-sides of the leaves. This will dislodge the insects, and also their eggs. Should the plants by any mischance become infested, then syringe them immediately and dust with sulphur. In the second season, when they have done blooming, they may be dried off a little and then pruned close back. After they break, thin out the superfluous shoots, shake the soil from the roots without injuring them, and repot into fresh soil. The treatment as to temperature, potting, and watering will be the same as during the first season. In this manner handsome plants of this *Linum* may be grown with little trouble, and the display of bloom will be very striking.

A.

### SPECIFIC VARIATION AMONG ORCHIDS.

WE may search through the entire vegetable kingdom and find but few classes of plants that vary more than Orchids do, so far as depth and richness of colouring and the relative size and shape of the flowers themselves are concerned. They also vary greatly in regard to constitutional vigour, as may be proved by growing a batch of newly imported plants of the same species under precisely the same conditions, when it will invariably be found that some grow much more vigorously than others, although there were no external signs of superiority to be detected amongst them, even by the most experienced grower, when they were first potted. As a striking illustration of their variability, I may cite the lovely winter-flowering *Lycaste Skinneri*, which varies in colour from the purest white to a very deep rosy variety, having a deep crimson lip; and this variability is equally apparent in other species belonging to different genera, which run from the typical form into the most distinct and beautiful

of varieties imaginable. Cattleyas are notorious for their protean variability, while the chaste *Odontoglossum (crispum) Alexandræ*—that queen of *Odontoglossa*—is extremely variable in the size and colouring of its blossoms. *Phalænopsis grandiflora* exists in many different forms in our collections, several of which are well marked and distinct, not only in the breadth of their sepals, the depth and diffusion of the yellow colour on the lips, but also in the length and breadth of their leaves, as well as in constitutional vigour. The same remarks apply to several other species, as *P. Luddemanniana*, *P. amabilis*, and *P. Schilleriana*; the latter has the most robust constitution of any species in this truly superb genus, and it is the only species that will subject itself to cool treatment. I would here remark that the mere mention of the breadth of a flower gives no substantial proof of its being a first-class variety, since many long-petaled flimsy flowers measure a good deal across, but are comparatively worthless, since they lack breadth and substance in their sepals and petals.

In one of the finest collections of *Phalænopsids* in this country there are some twenty or thirty imported plants, which vary greatly in breadth of petal and substance. Hence it becomes apparent that when we purchase Orchids, we should be careful to select as good varieties of them as possible. There are some Orchids, too, which vary greatly, not only as has just been related, but also in the length and thickness of their pseudo-bulbs, and in their flowering propensities. For an example of this, take *Lælia majalis*—the *Flor de Maio* of the Mexican Spaniards—of which there are two distinct varieties differing in the length of their pseudo-bulbs. The short-bulbed variety blooms with tolerable regularity, while the other may be grown on for years without its ever producing a single flower. Mr. James Anderson, gardener to F. Dawson, Esq., of Meadowbank, has succeeded in flowering this species regularly during these last few years. It will thus be seen that "good varieties" are those which bloom freely, and that produce large, richly coloured flowers of good substance. What, it may be asked, causes this striking divergence from the normal types in different species? We can only account for diversity in colour, size, form, and constitution by the fact that in their native habitats, where several species bloom in close proximity simultaneously, they are exposed to the fertilising agency of insects, and being reproduced from seed it follows that some proportion, if not all the seedlings, vary as has just been stated. Everyone who has raised seedlings of any class of plants will understand that they are apt to differ from the parent plant; more especially is this the case when these varieties are again cross-fertilised, producing other plants even more diverse than themselves. I willingly allow that local circumstances and conditions affect plants, and cause variety in individuals to a certain extent, when they exist under different surrounding influences, but the great bulk of our best varieties owe their beauty to cross-breeding, as effected by insect agency. We are well aware that nearly all the seedling Orchids raised in this country, with the exception of *Disa grandiflora* and *Cypripedium Schlimmii*, have proved on flowering to be more or less distinct from their parents, and this is a pretty conclusive proof that cross-fertilisation in their native habitats is the origination of all the beautiful varieties introduced from the tropics. This extreme variability in Orchidaceous plants adds an additional charm to their cultivation, for with what unfeigned anxiety does the amateur or professional cultivator watch an imported plant showing its flower-spike for the first time! How carefully he compares its pseudo-bulbs or foliage with those of its relatives, and if its external habit of growth does not betray him, if it really is a new species, or an extraordinary variety, with what genuine pleasure does he watch the delicate stranger unfold its floral treasures. Seeing, therefore, that Orchids vary so much in a wild state, and even under cultivation, need it be wondered at that portraits of such plants vary? The difference that exists between representations of the same plant in different books has often been a matter of complaint; but the disparity in question is not by any means greater than may be found to exist in the different varieties of the plants themselves from which the drawings were originally made.

F. W. BURBIDGE.

**Acineta Humboldti.**—Last summer I saw a pair of magnificent plants of this species, flowering in the gardens at Crow Nest, near Halifax, the seat of Sir Titus Salt, Bart. They were growing in wire baskets suspended from the roof, and bore twenty-six splendid spikes, thirteen on each specimen. On one spike alone I counted thirteen fine blossoms. Mr. Nicol, who is gardener there, grows a great variety of really good Orchids, though not favoured with the most approved structures for the purpose. *Acineta densa* and *A. Barkeri* are two of the best species of this genus, and bear golden yellow flowers, the former being spotted with crimson. *A. Humboldti* unfortunately does not last well when in flower, and in this respect is surpassed by its congeners. In addition to the above, Mr. Nicol has been very successful with *Dendrobium densiforme*; some of his plants of it have bulbs 2 feet long, and in 1870 one fine specimen of this *Dendrobe* bore fifty-two spikes, which collectively had considerably over one thousand flowers, all fully expanded at the same time! In this collection *Chysis bractescens*, a beautiful but scarce Orchid, has also one large plump pseudo-bulb, nearly 2 feet long, and several smaller ones. This plant produces three or four spikes annually, and has borne twenty-six flowers fully expanded at the same time.—F. W. BURBIDGE.

## GARDEN DESTROYERS.

### THE LIME-LOOPER OR MOTTLED UMBER MOTH.

*GEOMETRA (HYBERNIA) DEFOLIARIA.*

THIS is one of the Geometer moths or Loopers, in which the male is provided with wings, and the female with none. The larva, the male, and the female, are all represented of the size of nature in the accompanying woodcut. The colour of the larva is ferruginous red above, with a yellow band along the sides, and a ferruginous spot, having a white centre, around each tracheal or breathing opening of the perfect insect. The male is very variable in colour and design; its normal pattern is that figured. The pale parts of the upper wings are yellowish or rusty yellow, the darker parts are ferruginous edged with black. The under wings are pale grey with a yellowish margin, and a small blackish spot in the middle. It sometimes, however, has no pattern on the wings at all, being entirely of a reddish freckled brown. The female is more or less yellowish, with no black spots on the back of each segment. The chrysalis is reddish brown.

This, if it were an Apple or a Pear, would be called a winter fruit, the perfect insect not appearing until the end of October and beginning of November. As soon as the female comes out she climbs up the stem of the nearest tree, where the male seeks her, and she lays her eggs at the base of the buds. These remain exposed to the weather all winter, and are developed by the return of warmth in spring, and the young larvae are hatched simultaneously with the bursting of the buds. The coincidence of the appearance of the leaves with that of the larvae is, of course, due to the same degree of warmth being necessary for the development of both; but it is not the less remarkable as an instance of the perfection of the adaptation of relations between plants and the animals that feed on them. As soon as hatched, they spread over the leaves, each on its own account; not associating in company, as many other larvae do in their young stage. They are very voracious, so much so that they often entirely strip the trees of their leaves; whence their specific name "defoliaria."

In the fine mornings of May or June the caterpillars of this moth may be often seen hanging from their twig or leaf by a tiny thread a foot or two in length, and swinging for hours in the gentle breezes of that genial season. Mr. Newman says: "This suspension seems to be sometimes a voluntary and recreational performance, for in passing through the woods I have seen thousands upon thousands of these beautiful caterpillars thus dangling in mid-air, and not unfrequently swinging themselves into my mouth and eyes." It is, however, also a means of protection, for when disturbed they let themselves suddenly drop from their perch, of course falling no farther than the length of their thread, which being very elastic lets them down easily.

By the middle of June they are full fed, and, descending to the ground, bury themselves in the earth very near the surface, and there undergo their metamorphoses. As already men-

tioned they remain in the chrysalis until the end of October. They are no ways particular as to the kind of trees on which they feed. The Lime tree is an especial favourite, also all kinds of fruit trees and Thorns; the Oak and other deciduous forest trees are also subject to their attacks.

This is one of the few insects for whose ravages the entomologist can propose a remedy drawn from the special structure and habits of the insect itself. The metamorphoses taking place in the ground, and the female being apterous, and requiring to lay her eggs beside the buds high up in the trees, are a concurrence of special circumstances which suggest an easy means of prevention. As she begins her course on the ground and has to ascend the trees before she can do any harm, and having no wings by which to fly up to the branches, must creep or walk up like any other walking or creeping thing, it is plain that if means be taken to prevent her getting up, the buds above are safe. The first mechanical means which were taken for this purpose, was enclosing the stem of each tree in a close fitting wooden boot, which was smeared with tar. It does not appear, however, that such a wooden boot is necessary. It is sufficient to smear the stem itself for a broad space near the bottom with coal tar or any gluey substance at the proper time, *i.e.*, in the end of October and in November. In attempting to ascend the female gets entangled in this and perishes, without ever having the opportunity of laying her eggs, and as they usually amount to

The Lime-looper.

300 or 400 in number, it is obvious that the gain is considerable for every female so destroyed. It has been objected to smearing the stem of the tree itself with tar that this may injure the timber by the tar soaking through the bark and interfering with the ascent of the natural sap. We believe this fear to be imaginary; but to remove all doubts on the subject, some less penetrating glue may be substituted, or the part of the stem which is to be covered might be previously protected by some hard varnish, or what is called distemper. A mixture of tar and cart grease has been found to answer without injuring the trees, unless applied in the spring months when the sap is rising. Beating down the caterpillars into a sheet spread below the trees has also been had recourse to; but that is not nearly so efficacious a plan as the preceding, although it has the advantage of being more immediate, for the preventive cure of course only applies to the following season.

A. M.

**Caterpillars on Cabbages.**—One of my friends, a landed proprietor in the Ardennes, informs me that, one day, having observed in the garden of a peasant that the Cabbages were covered with froods of the common Bracken (*Pteris aquilina*), he inquired the reason, and was told by the owner that it was a certain and easy way to get rid of caterpillars. My friend made a trial of the remedy himself, and he assures me that in one hour after the Bracken-froods were laid on not a caterpillar was to be seen. Elder-leaves are said to be equally efficacious.—E. M., in *Belgique Horticole*.

VEGETATION IN WESTERN AUSTRALIA.

KING GEORGE'S Sound, as most of your readers will be aware, is the coaling station of the Peninsular and Oriental mail steamers, the chief town of the district being Albany. The place, like so many Australian towns, consists of a main street with here and there an effort on the part of cross streets. These efforts, however, do not appear to have been long sustained—appear, in fact, to have been checked by the prospect of people being led recklessly to dwell in the bush. The streets are, therefore, cut off short, but the eye is able to detect the projected line from the appearance at intervals of a stray cottage, where some spirit more courageous than the rest has struck out and established a home for itself. Arriving recently at the Sound, about midnight, on a homeward trip, I obtained permission to go ashore in the mail boat. The time was early morning (two a.m.). A long and weary pull, with a Lascar crew, against a rapidly declining tide, and in the teeth of a squall, brought us within sight of the still sleeping township, and a vigorous spurt by the oarsmen laid us alongside the steps of the pier. After depositing the mails in the post-office—a substantial structure, which appears to do duty as custom-house and generally useful depôt for the settlement's departmental affairs, I managed to get a shake-down till daylight. Starting then I ascended Mount Melville, which rises to the left of the town. At its foot passes the turnpike road to Perth, a town lying inland some 256 miles. The low-lying grounds at the foot of this mountain were clothed with plants in most gorgeous blossom, many of them being new varieties of plants familiar to me in the Victorian bush. In less than an hour I gathered more specimens than my arms could encircle; and filled my pockets to overflowing with cones and seeds of new and charming plants, suitable for garden decoration. Leaving these at the hotel I proceeded to explore a promising tract of country lying to the right of the town, from which abruptly rises Mount Clarence to the height of about 700 feet. Here and there the granite crops out on the sides of this mountain, in places many roods of the surface presenting a bare, unbroken face of stone, from which solid blocks as large as churches might be quarried. At the foot of this mountain, and covering the lower grounds to the contour-line of the coast, a vast number of flowering shrubs is to be found, and I very much regret that the short stay of the steamer prevented me from doing even scant justice to the floral gems which bedecked valley and mountain. At this, the late winter season of the year, numerous springs trickle slowly from the sides of the mountain; their course being marked by narrow lines of a pure white silver sand, the lighter and peaty portions of the soil and other soluble matters being washed to the lower levels. This sand, and even the soil, is destined some day to attract the attention of nurserymen in the other Australian Colonies, who still import Reigate sand for purposes of propagation, and who are often put to great inconvenience through the difficulty of procuring suitable soil for potting purposes. I can only notice here a few of the beautiful things so abundant on this mountain and in the rich valley at its foot, but these will serve to show the floral wealth of the district.

A shrubby variety of *Solanum*, with large cream-coloured flowers and broad handsome foliage, is very highly perfumed, a drawback to its culture, however, being that its petals are poisonous, several accidents to children in the district being recorded. Two varieties of *Chorozema*, with orange and carmine flowers, grow very generally here; one of climbing habit, and bearing flowers twice the size of *C. cordatum*. Two pink *Boronias* are found in the higher grounds, and hereabouts *Boronia megastigma* has its home, the air for many hundreds of yards being laden with its ravishing perfume of lemon and rose. Two varieties of *Hovea*—*elliptica* and *ilicifolia*—are covered with their rich cobalt racemes of blossom, the flowers resembling in shape those of the *Kennedya*s, though the colour is an intense blue instead of purple, and each bloom is much larger than that of the *Kennedya*. These two *Hoveas* are exceedingly valuable, their dwarf habit, unusual colour, and their season of blooming rendering them great acquisitions, not only for English greenhouses but also for the borders of the Australian flower gardens. A fine *Dillwynia*, much brighter in colour and larger than *D. cine-*

rascens of the Victorian bush, is here truly beautiful, its rich and abundant orange-yellow blossoms being very conspicuous. The district is also rich in Banksias, fully twelve kinds being procurable within a mile of the town. *Banksia coccinea* is perhaps the most showy as regards blossom, the whole bush being scarlet from the prevalence of this variety. Seedling plants of not more than a few months' growth are in bloom, while trees of all stages beyond this are covered with scores of flower heads. Unlike many of the Banksias, this showy variety blooms early when young, and the tree has not to attain timber proportions before it can be seen in perfection. The plant is not found in the gardens of Melbourne and Sydney, where it would be perfectly at home and would prove unusually attractive in shrubberies. *Banksia Brownii*, *B. littoralis*, and *B. grandis*, the finest of the genus, are all met with here, as are also many varieties as yet unnamed. There are many kinds of *Acacia* here new to me, but these are not very noteworthy; the *Acacia Drummondii* grows further inland, and is perhaps the most striking member of this extensive family. Two very compact-growing *Andersonias*—one with blue and white, the other with purple and pink blossoms—would be a great acquisition to the flower gardens of other parts of temperate Australia and to the conservatories of Europe. Among other interesting plants were to be seen several kinds of *Kennedyia*, *Pimelea decussata*, *P. nana*, *P. macrocephala*, and *P. Hendersonii*; *Boronia elatior* and other species, a *Gompholobium*, a fine large purple and white flowered *Lobelia*, *Gastrolobiums*, a rich golden flowered shrubby *Grevillea*, *Swainsona*, two kinds, fully fifty *Epacris*s, and other plants, several with very showy Papilionaceous flowers.

In the immediate vicinity of King George's Sound there is scarcely a tree of any size; even the *Eucalypts* are, by reason of their full exposure to southerly winds, reduced to mere shrubby growth, the largest tree near the coast being the weeping *Melaleuca*, which fringes the shore near Albany. Growing along the streets is that pest of the Melbourne pastures the "Cape weed" (*Cryptostemma calendulaceum*), and on the cultivated patches the common Sorrel is very prevalent and troublesome. I was fortunate, just before leaving, in meeting with an old companion of Drummond, a man who also accompanied Muller on his short botanical trips in the district some four years ago. This elderly gentleman is a diligent collector of seeds in Western Australia, a close and tolerably systematic observer, and I was able to get seeds from him of most of the plants I had collected for my "*Hortus Sicus*." The richness of the district in plants adapted for garden decoration greatly surprised me, and I was still more surprised to find plants of which so little is known by cultivators in the other colonies. Doubtless most of them have been observed by botanists, but, strange to say, these have done but little towards diffusing a knowledge of valuable plants among the general community. If, instead of contenting themselves with the mere addition of a plant to their herbariums, botanical collectors would call the attention of nurserymen to the value of a new plant from a decorative point of view, they would secure such being sooner known by gardeners.

As matters are managed now, in Australia at least, half a century may elapse before the good qualities of the indigenous plants, and their value in ornamental gardening, become generally known by the public. Fully fifty plants of rare qualities, not one of which is to be met with in the gardens of Melbourne or Sydney, are to be found in the greatest abundance at Albany. It is just possible that a better knowledge of their value may prevail in Europe, and that there expensive appliances may be used to bring to perfection plants which in all the Australian colonies might be grown without the least trouble. It certainly is not creditable to the gardeners of Victoria, New South Wales, and Queensland that they should be almost totally unacquainted with them.

W. C. C.

**Seaside Plants.**—Two valuable plants that will flourish even under the influence of the sea breeze and in the teeth of the wind are *Veronica Andersoni* and *decussata*. These grow and flower where a Nettle would hardly live. I have seen plants of them at Southport, where there is very little but salt breezes and sand.—J. WILLIAMS.

## THE FLOWER GARDEN.

### VARIETY IN SMALL GARDENS.

A MATEUR cultivators, who are not bound to the delusions of the bedding system, find exhaustless amusement in collecting representatives of various families of plants adapted to the means at their command for keeping and cultivating them. Where the bedding system reigns supreme, this is impossible, for greenhouses, frames, and nursery beds are all filled to overflowing with the monotonous round of subjects that are to be planted in May, that are to bloom in July, that are to be ragged in September, and that are to be honed in October, leaving the places they occupied empty and cold till May returns. Collecting allies horticultural recreations with botanical science, affords scope for the exercise of thought, and occasionally quickens inquiry and research; it instils into the mind a larger knowledge, and into the heart a warmer love of plants than is possible where the garden is kept as a place for a mere display of colour during three or four months of the year. It is next to impossible to avoid collecting when an interest has been created for certain forms of vegetation. The lover of Ferns is always in want of certain species and varieties; the cultivator of succulents, of bulbs, of hardy herbaceous plants, of choice trees and shrubs, finds that his possessions are so many keys to the vegetable kingdom, and at every advance of knowledge accomplished by their aid, he learns how many more interesting and beautiful plants there are in the world which he has not yet obtained, and which he would rejoice to possess. Collecting is, in fact, an exciting pursuit, and we sooner forgive a man for wasting his substance in riotous gardening, when this passion has seized him, than if he were under a *Geranium* or *Verbena* spell, revolving amid only half a dozen species of plants, and deriving no higher pleasure from his garden than repeating upon its surface the designs he is already tired of in carpets, chintzes, and wall-papers. For the public promenade, as for the great garden, where there is room for everything, and ample means to boot, good bedding is one of the necessities of the decorative part of horticulture; but in the small garden, which is like an extension of the drawing room, or a sort of outdoor parlour, something more is wanted than dabs of yellow and red, which—

Like the borealis race,  
Flit ere you can point their place.

We want entertainment the whole year round, beauty for the eye, and with it fragrance, agreeable associations, variety, and something to engage and interest the mental faculty. In place of the scrubby evergreens that are tolerated, because the bedding, like the Dragon of Wantley, swallows up everything but itself, we ought to see in private gardens a considerable variety of the most beautiful shrubs and trees, deciduous and evergreen; the first so various in form and leafage, and many of them so magnificent when in flower; the second warm and rich in the depth of winter, making the place look like home, so that a glance from the windows neither chills nor repels, as must be the case when a person of any taste looks out upon a dreary parterre that is known to be of use only in the height of summer, when mere colour is least wanted, and when, in many cases, the family are away, and see nothing of it. And for summer and autumn, and even for winter, the hardy plants comprise myriads of fine subjects, some showy enough even for a vulgar taste, but many more beautiful in the true sense of the word, with grace of form and delicate harmonies of tints, and characters so individual that one deserves to have a history, and to have that history told to all admirers. And when winter comes again, the variegated leaved and berry-bearing shrubs that are within the reach of English cultivators would suffice to effect an apparent change of climate. It is enough for us to be frozen to-day and roasted to-morrow in this wayward, changeable, ungenial, unfriendly clime; we need not make our gardens lugubrious to increase the horror. Yet this we do, and only at rare intervals do we meet with examples of what English gardens might be in warmth, cheerfulness, richness, and variety even in the very depth of winter. F.

### CHAMÆBATIA FOLIOLOSA.

THIS unique little shrub, so remarkable for the Fern-like beauty of its leaves, belongs to the Rose order, and in a wild state occurs naturally in the hill country of California, where it quite covers the ground, and is named Tarweed by the settlers. This name is given in consequence of the powerful and somewhat disagreeable odour given off by the plant when touched or walked upon, and which is very apparent in the air where the plant is common. It is seldom seen above

a foot high, forming, however, a dense shrubby turf, spreading everywhere under the great trees. This, however, does not prove it to be a shade-loving plant, as the tops of the high Pines are so compact that the sun frequently plays freely on the dwarfer vegetation. In further explanation of this, it may be mentioned that very frequently on the Sierras the pines are dotted about in an open manner quite different from what is the rule in the Pine woods of Europe and the eastern side of America. The Tarweed is sometimes, though not often, seen in English stoves and greenhouses. My object in directing attention to it now is to point out the probability of its succeeding out of doors in the rock-garden or in favoured positions on well-drained banks. I have seen it growing abundantly in places where there were sharp frost and snow early in November, and where it must have endured

Chamaebatia foliolosa.

much cold in winter. In trying it out of doors, as sunny a position as possible should be given to it, and it should be planted in well-drained sandy loam. R.

PRIMROSES.

SOME twelve or fourteen years ago, when residing in a distant county upon the table land of England, I had a beautiful collection of varieties of the common Primrose, and when I speak of varieties it will be seen I mean something more than did the person described by one of our popular poets, who to denote his want of feeling said :—

“A Primrose by the river’s brim  
A yellow Primrose was to him,  
And it was nothing more.”

But mine were “something more,” for though but a simple Primrose the scale of colour ran from pure white to bright crimson, with all the varied shades of purple, rose colour, lilac, mauve, and some of the neutral tints. However, they were all beautiful. Leaving the locality at the time when the Primroses had died down I had no means of securing them, and since then the mansion has been burned down, and the gardens have fallen into decay. Writing, however, a short time back to an old friend in the neighbourhood, I mentioned incidentally these Primroses, and, giving him “a clue to their secret hiding place” in one of the woods, he has rewarded me by sending a collection of the flowers. It is surprising out of what simple materials really gay and beautiful bouquets may

be formed. These flowers now standing before me in a glass dish would grace the boudoir of an empress. At present the plants are a mere *omnium gatherum*, a mixed mass of colours, but when put under proper training, and another season they are massed either in straight lines or consecutive circles of well-contrasted colours, they will create quite a new feature in the flower garden, and become the admired of all admirers. By what wild freak of nature the “Primrose pale” was lured from the path of colour-constancy I cannot imagine, but it is quite certain that she has been coquetting with some ruddy complexioned gentleman, and whether that may have been a bit of stray pollen from the double red, crimson, or lilac Primrose I cannot tell, or whether with the aid of the bees she has borrowed a blush or two from the Chinese Primula, Auricula, or Polyanthus, matters not; we have got the colour and now we must intensify and vary it as much as possible. The varieties now before me, picked up at random, are sufficiently defined :—crimson, deep rose, rose, lilac, mauve, dove colour, white, and yellow. Many intermediate colours might be named by those who are inclined to hair-splitting in the manufacture of varieties, but I am content with a few well defined colours, and those I have enumerated might be very effectively grouped, especially if liberally intermixed with the white or yellow varieties. Primroses cannot be classed amongst the ephemera of spring, for though, under favourable circumstances, early in the development of their flowers, they continue for a long time to give a succession of blossoms. Plants of the common kind which with me were blooming in November are blooming still, and no doubt the coloured varieties will do the same. These varieties alone would make a spring garden quite gay, but when we come to look to the varieties of Polyanthus, Oxlip, Auricula, especially the lovely Alpine ones, and the innumerable species and varieties from temperate as well as from the coldest parts of the world—from the inhospitable wilds of Siberia to Egypt and the Himalaya mountains, we find a variety of colours and elegance of form peculiarly suited to the purposes of the decorative gardener. Most of them are of simple culture, and by division of the root and by seed they may be increased almost indefinitely. What a wide field this family opens to the hybridist. With comparatively limited means the Cyclamen, under the persevering intelligence of Mr. Atkins and the Messrs. Henderson and Son, has yielded a rich harvest of beautiful forms and colours, and no doubt the Primula would repay similar attention. I can conceive no more agreeable employment for an amateur, either lady or gentleman, than that of raising varieties of these beautiful plants. A collection of the kinds, a small frame and a camel’s hair pencil is all that is required. Watch the flowers daily and when in a fit state, that is full grown, impregnate them by transferring with the hair pencil the pollen of one species or variety to the stigma of another; watch narrowly for the seed, and when it is ripe sow it immediately, and every year you may have hundreds of young plants to bloom; and with this certainty that all will be beautiful if not distinct and new.

W. P.

NOTES AND QUESTIONS ON THE FLOWER GARDEN.

**Monthly Roses.**—A few days ago I saw ten or twelve lovely peach-coloured buds on a plant of the old monthly Rose, and a much larger number of buds not so far advanced. The plant in question was growing in a sunny corner, and almost made one forget that we are so near mid-winter. This now somewhat neglected old plant will well repay any one who may give it a sheltered nook and a few minutes’ cultural attention once or twice during the season.—F. W. B.

**Sporting of Bouvardias.**—Bouvardias are among the most valuable and pretty of our winter-blooming plants, as their small, delicate flowers seem never to be out of place in any style of basket, wreath, or bouquet. Scarlet varieties and species were formerly the most common; but within the past few years several new white varieties have been introduced, the two most valuable sorts having originated in America, and being known as Bouvardia Davidsonii and B. Vreelandii. Neither of these were raised from seed, but are what are called “sports” of the B. Hogarth, a well-known scarlet variety or species.

**Winter Flowers.**—Cyclamen coum opened its blooms with me on New Year’s Day, as did also the Christmas Rose. The Cyclamen has bloomed four years with me, twice opening on New Year’s Day, once on the 8th of the month, and once on the 12th. Some assert that Cyclamen when at rest require to be kept dry, but as this plant grows above the roots of a Clematis Jackmanii, which receives large doses of liquid manure when the Cyclamen is at rest, the dry theory must be wrong, as also must the system of planting the corns upon the surface. I must also add Eranthis hyemalis to my list of New Year’s Day flowers.—G.

## THE FRUIT GARDEN.

### THE HOME OF THE APPLE TREE.

THE unchanging character of the Crab, the reputed parent of the fruit which we call the Apple, and the constancy with which it produces its excessively sour and unpalatable fruit in this country, perhaps justifies the following inquiry put forward by Mr. Pearson, as to the origin of our cultivated varieties of *Pyrus Malus*, and gives some show of reason for the doubt which he expresses as to the general accuracy of the received opinion that the Crab is the immediate parent of the Apple.

"Where did our eating Apples come from?" says Mr. Pearson. "I am not Darwinite enough to believe our Ribston Pippin ever came from the Crab of our hedges, any more than I believe that our editors had monkeys for their ancestors. George Chaworth Musters mentions in 'Travels in Patagonia,' large woods of Apple trees which the Indians visited every year to gather the fruit. These are spoken of as far distant from any settlements of the Europeans. Then, again, Adams, in his 'Wanderings of a Naturalist in India,' writes of the Apples, Apricots, Walnuts, &c., of Cashmere, as if he had found them at home. In spite of the antiquity of cultivated Apples, one often sees writers take it for granted that the hedge Crab improved is the source of all our varieties of this useful fruit. Why do they not talk of the time when our cats were tigers? What is the history, as far as known, of our cultivated Apples?"

Alph. de Candolle, in "Geographie Botanique raisonnée," says that *Pyrus Malus*, the source apparently of all the varieties of our Apples—sour and sweet, grows in temperate Europe and in the region of the Caucasus. The Romans and Greeks cultivated several varieties under the name of *Malum*. The word *Pomum* was applied in Latin to all fruits, round or fleshy. The name *Pomme d'Api* comes probably from the variety *Appiana* introduced by Appian, according to Pliny.

The names of the Apple differ less from one another in the ancient languages of Europe than those of the Pear. This makes us suspect a primitive country, less extensive than that occupied by the Pear, varieties less numerous, and a culture transmitted from people to people by imitation, rather than the finding of wild Apples in different countries. The root of almost all the names is *ab, ap, al, ar, af*. The Tartars, Hungarians, and Tarks call the Apple *alma*; the Bretons call it *aval, avalen*; the Gauls, *afalen*; the Germans, *apfel*; the Russians, *jablou*; the Poles, *jablon*; the Latins, *malum*; the inhabitants of Biscay, *sagara*.

The Apple is cultivated in the north of China, in the north of India, and more commonly in the Vale of Cashmere, and the neighbouring country. The Sanscrit name of the Apple is *Seba*, which is not very far from European names, amongst others the Basque. The Arab name *Tufa*, and above all, the Chinese name *Pim Po*, are very different. Thunberg does not indicate the Apple as being in Japan, and this makes me presume it is not ancient in China. From researches thus pursued through the records of the various civilised races of Europe and Asia it seems that an edible fruit identical with our Apple was in existence at remotely historical periods. Fruits, such as the Apple and Pear, Plum and Cherry, ameliorated and improved by the cultural skill and care of races of whose civilisation we know nothing, but that they had achieved a certain amount of success in the cultivation of fruits, and that some of these fruits developed into the form and quality that even now belongs to them, were obtained by the Greeks and Romans, from people who were to them ancient and mysterious, and were cultivated, improved, and finally distributed throughout the continent of Europe by the great colonisers and conquerors who flourished 2,000 years ago. The Romans were doubtless the first to distribute the hardy fruit trees familiar to them throughout their western dependencies. The strong botanical affinity existing between the wild and cultivated form of *Pyrus Malus* may justify the assumption of consanguinity generally entertained; but the obdurate and persistent acerbity of the wild Crab of Britain not unnaturally provokes the question of ancestry, and many find it hard to admit the close relationship

of the sweet rosy Apple with the small green sour Crab. The explanation, however, may be found in the fact of the variable constitution and production of a fruit tree exposed to different climatic influences. We know in our cultural experiments with any fruit how much the development of its best qualities depends on conditions of climate, and a Crab on the sunny slopes of the Caucasus or other favoured situations may have yielded more readily to the cultural cares of man than the same tree would have done in England. It seems not improbable that a form of *Pyrus Malus*, modified by the influence of a climate favouring the development of the saccharine element in the fruit, was the parent of the great family of Apples now spread throughout the temperate regions of the earth.

*Belvoir.*

WILLIAM INGRAM.

### CULTURE OF THE APPLE AND THE PEAR.

WHEN grown as standards on the natural stock, both the Apple and Pear delight in a deep, strong loam. Three feet of such a soil, thoroughly well drained, is not too much, and at least 2 feet should be secured before planting, if permanent and satisfactory results are expected; therefore, where the soil is naturally shallow and the subsoil bad, the ground should be broken up and trenched to that depth, either removing the subsoil altogether to the necessary depth, and making up with fresh loam or good soil, or incorporating it well with the top soil in trenching, if it is not actually of a deleterious character. Manure may be applied after planting in the form of mulchings, with great advantage; but it is not advisable to trench it into the ground unless the soil is poor and light, in which case cow-dung is the best and most lasting manure that can be used. On the other hand, when the soil is stiff and tenacious, it should be meliorated with plenty of leaf soil or decayed vegetable refuse of any kind, and sand; but good loamy soil—not necessarily turfy—is, as a rule, the best restorative that can be applied. In wet situations draining is of the highest importance, but in dry localities it is sometimes not needful at all; circumstances must be the guide in such cases. Standards are generally planted from 20 to 35 or 40 feet apart each way, according as they are likely to make a luxuriant growth or otherwise, but 30 feet will be found a suitable distance for permanent trees; and it is not a bad plan to plant between with supernumeraries, which allows a greater variety to be planted, and those which are found to suit the locality best can be retained, and the others removed when the trees get crowded after a few years. In orchards of small extent, Apples on the English Paradise stock should be chosen, and the trees may be planted half the above distance apart. Trees with clean, straight stems, and such as show a disposition to grow freely, should be selected; and, though it is better to plant as early in autumn as possible, they may be planted any time between the fall of the leaf and the breaking of the buds in spring, when the weather is open and moist. With the exception of thinning out the shoots when too crowded, and shortening back such as are getting too much ahead of the others, so as to secure a round and well-shaped head, the less standards are pruned the better. The oftener the knife is used the oftener it will be required, while less fruit will be the result, and root-pruning will be a periodical necessity.

#### PYRAMIDS.

As it is in every way better for those who contemplate planting these to buy established trees, rather than attempt to originate them from the beginning, I will say nothing about training from the maiden tree. Nice trees, already trained into rudimentary shape, can be had from any respectable nurseryman cheaper and better than they can be got up by the amateur himself. When the Apple and Pear are grown as pyramids on the Crab or Pear stock, they require a considerable amount of attention in the way of summer pinching and root-pruning to restrain their vigour and to secure a fruitful habit. The most fruitful trees of this kind I ever saw were trained as pendulous pyramids—perhaps the best form of training; but it should not be attempted unless it can be carried out systematically and well, for trees once trained in this way, and afterwards neglected, are unsightly objects. Where the pendulous form is adopted, the following directions must be attended to:—Assuming that we have a fairly pyramidal-shaped young tree—that is, with a straight central stem, furnished regularly with shoots from within one foot of the ground to the top—to begin with, it should be encircled at about 6 or 8 inches from the ground with a hoop of iron wire, fastened with staples to the tops of short oak posts driven into the ground for that purpose, at equal distances apart round the tree. The lower shoots of the tree should then be tied down regularly by their points to the wire; the second tier of shoots

should be tied in the same way to the first; the third to the second; and so on to the top of the tree. The advantages of this form of training are that it checks the vigour of the tree, and induces the formation of fruit buds along the pendulous shoots, instead of a luxuriant growth of wood, such as upright-trained trees are disposed to make. A fruitful disposition must also be encouraged by not tying in too many shoots, allowing such as are retained to extend in length till the tree has attained the desired circumference, and by pinching assiduously during the summer, to two or three leaves, all laterals that push from the pendulous shoots; in fact, each shoot, if properly cared for, should be like a little cordon growing out from the stem of the tree. If pinching and thinning have been regularly attended to during the summer, little pruning will be required in winter; but the trees should be gone over, and such spurs as have been left too long should be shortened back, and the branches regulated and tied down. Such trees also as seem to be growing too luxuriantly should be root-pruned. About the end of October is the best time for this, and the operation is performed by cutting a trench round the tree about 3 or 4 feet from the stem, according to the age and vigour of the tree, and cutting off all roots that extend beyond that distance, and such as are going down into the subsoil. Indeed, the soil should be removed sufficiently to allow the spade to be pushed right under the ball of the tree from all sides. My own practice is to lift about one-third of all our pyramids every autumn; in this way they are all lifted over in three years. Mulching summer and winter should also be practised regularly. These remarks, it will be seen, refer to trees grafted on the natural stock, and so far as relates to pruning, pinching, and root-pruning, they apply also to upright-trained or natural pyramids. In these the object is also to secure and retain a straight central stem, to have it well furnished with branches from the base, and by systematic pinching and pruning to keep the tree as nearly in the form of a cone as possible. With upright pyramids, however, it is not the practice to allow the leading shoots to extend at the same rate as when they are trained in the pendulous form, but to pinch them the first time during the summer to 8 or 9 inches, the next time to 3 or 4 inches, less the third time, and so on. The side shoots or laterals may be pinched the first time to 3 or 4 inches, and proportionally shorter afterwards.

PYRAMIDS ON THE QUINCE AND PARADISE STOCKS.

The object of grafting the Apple upon the Paradise Stock and the Pear upon the Quince is to secure a dwarf habit, early maturity, and quick returns. Both stocks being shallow rooters, they are also adapted for planting on thin soils, where, if the Pear stock was used, the roots would be sure to penetrate the subsoil, and failure, partial or altogether, would be the result. The Pear is disposed also to make a too vigorous growth in wet and late situations, particularly in deep, retentive soils; hence the value of the Quince or Paradise stocks under such circumstances. Otherwise, in moderately deep and healthy soils, the Pear is the most natural and best stock for the Pear in every respect, if attention in the way of root-pruning, pinching, &c., is given. The treatment of pyramids on the dwarf stock differs from what I have already recommended for those on the natural stock in the matter of root treatment only; for, while the roots of the Pear and the Crab need to be kept within bounds by constant cutting and lifting, those of the Quince and Paradise require to be as constantly encouraged to grow by surface dressings and mulching. The ground should not on any account be dug about the roots of the trees, but annually top-dressed with rich soil, taking care always that the graft is not buried in so doing.

ESPALIERS.

This is a very excellent way of training the Apple and Pear, and is perhaps the best plan that can be adopted when fruit trees are grown round the kitchen garden quarters. Espaliers bear better than standards, occupy less space, and interfere but little with the cropping of the ground with vegetables. Referring your readers to your advertising pages for information regarding the erection and construction of espalier fences, only premising that the wires are stretched about 8 inches apart, I will at once speak of the mode of training, which is perfectly simple. For espalier training it is best to begin with maiden trees, that is, young trees with only one shoot to them. These should be planted against the wires 20 feet apart, and be cut down to about 2 inches below the bottom wire. In spring three or four shoots will spring from below the cut; the highest should be trained straight up, and two of the remaining strongest and most conveniently placed should be trained horizontally along the bottom wire, on each side of the stem, and the other shoots, if any, may be cut clean away. The central shoot, which will be inclined to grow the strongest, should be stopped at the height of 18 inches or so, in order to throw the sap into the two horizontal shoots, which cannot be encouraged to grow too much. At the

winter pruning they should be left entire if they ripened to their extremities, and the central shoot must be cut down, this time to the second wire, which will leave the tree at the end of the first year with two well grown side shoots only, and a central shoot about 8 inches high. This will break the second year again below the cut, and furnish limbs on each side, which must be trained right and left, the same way as before, to the second wires, and the leader taken up and stopped again; and this process must be repeated until the top wire is reached, which, supposing the fence to be 5 feet high, will take about seven years. But by that time the trees will have extended horizontally to at least double their height, and borne several crops of fruit. The only other attention the trees will require is pinching back the lateral shoots that grow from the horizontal limbs to two or three joints, in order to induce the formation of fruit buds, and to keep the same within proper bounds by shortening the spurs judiciously at the winter pruning, taking care always to cut back to a bud, and to secure generally an even and well furnished limb. The different varieties of the Apple and Pear vary so much in different localities—sometimes one sort succeeding as a standard and espalier at one place, and perhaps requiring a wall at another not far distant; here doing best on the Quince and Paradise, and there on the Pear and Crab—that I do not think it advisable to append a list of kinds for general cultivation, but would advise those who contemplate planting to ascertain at some good garden in their own neighbourhood what sorts are found to do best. A little pains taken in this way at the outset will repay the trouble.

J. S.

AMERICAN BLACKBERRIES IN ENGLAND.

At last these remarkable fruits have had a little attention from one of our best gardeners. "For the last two years," writes Mr. Tillery, in the *Florist and Pomologist*, "I have grown great crops of Lawton American Blackberry, and find it to make a capital preserve when mixed with a few Apples to take off the sweetness. Wet seasons like the present seem to suit it best, for the bushes are loaded with fruit of a far larger and firmer consistence in flesh, and of a better flavour than the common English Blackberry. I believe there are many varieties of the American Blackberries, but the Lawton is the only one I have yet cultivated. I grow the plants of it in rows, like Raspberries, selecting two or three of the strongest shoots made in the summer, and after cutting away the fruiting canes when they have done bearing in the autumn, the young shoots are tied up to stakes placed in a slanting position, like Raspberry stakes. The stakes, however, must be longer than for Raspberries, for this Blackberry is a very strong, rampant grower, like many of the English sorts, and the more room it has the larger will be the growth. The soil it does well on here is very strong, with a clay subsoil, but I should think any soil would suit the plants, if they were well watered in dry summers during the flowering time. There being a great paucity of fruit this year for the blackbirds and thrushes, I expected they would have commenced their raids upon this Blackberry as soon as it was ripe, but they seem to let it alone, and confine their attention to the rows of the autumn-fruited Raspberries growing in the same quarter of the garden. The first year I fruited this Blackberry I saved some of the fruit for seed; and having raised some young plants, I have distributed and planted them in some of the hedge-rows and plantations about, so that they will very likely multiply and replenish the Blackberry-pickers' baskets with their fruit. The Lawton Blackberry is very distinct in its foliage from ours, its leaves being more lacinated, and of a deeper green colour, and keep nearly so all through the winter."

KEEPING FRUIT.

A FEW principles are important in keeping fruit, particularly Apples. The first is coolness of temperature. If too warm, they (the Apples) will mature—so that temperature is the important thing. Keep as cool as possible for long keeping. A little frost, gradually let out, does not seem to hurt. A low, uniform temperature, say at 40° or a little below, just avoiding the frost, is all that is wanted in the line of temperature, so far as Apples are concerned, and other fruit comes under the same general head. It is no difficulty to keep this point in the winter, only be sure and have your cellar or fruit-room warm enough to withstand the heaviest cold. If in the warm days there is a tendency to too much warmth open the windows or doors, do not neglect them. The next great consideration—and it is almost equally great with the first—is, the hygrometric condition. If too moist, you may be sure your fruit will rot—will mould. If too dry, it will shrink—that is, lose its moisture—and this is almost as bad as rotting. Much can be done by regulation here, even if the

apartment is inclined to one or the other extreme. Where there is much moisture, open bins will keep your fruit either from rotting or shrinking. So will open barrels where there is less moisture; they require a drier atmosphere, as they are more confined. Closed tight in a damp room, they are sure to spoil; we have known them to be a sunken mass of rot and mould. If the air is quite dry, the barrel is the thing, either shut tight or merely covered over. We have known Spitzenbergs to come out in April, headed close, almost in the same condition as they went in. They were more matured, and were highly coloured. These were headed up in the autumn and put into the cellar, a dry one, and left there till April untouched. Growing rank and watery (in a wet season) fruit will not keep so well, and the winters are sometimes more moist. Where there is a condition neither too wet nor too dry—that is, not known for its extreme—this is what is wanted, and most cellars are of this kind. It is therefore in general safe to trust Apples to barrels, covered up, whether absolutely tight or with a little air circulating. We prefer the latter as a general thing. We usually let our fruit sweat in outbuildings before we store it for winter. This is at least a safe plan, and therefore we practise it. There would be more uniformity of temperature and moisture were it immediately taken to the cellar, but the sweating which would follow would be long and profuse. Never touch fruit after it is put in its winter quarters. If it is "bound to rot," as seems to be the case with some people's fruit, why it will rot—and it will rot the faster, and much faster, if you try to save it by sorting, but particularly by wiping also. This removes the coat (an oily covering), which is a protection, and a decided one—one nature seems to have provided for that purpose. In the spring sound fruit treated in this way is sure to last but a little while. When once rot has set in, the fruit should be used at once, what is good of it, but handle no faster than you use it.—*Cultivator.*

**The "Apple Cure."**—It appears, from the *New York Tribune* that the best food for animals is Apples. Two cows in an advanced stage of illness have, it is stated, been entirely cured by Apples. A horse, given over by veterinary surgeons, and turned out in a field to die, got access to an Apple tree, ate what he wanted, and immediately showed signs of improved health. His owner, acting on the hint, fed the beast daily on a peck of Apples, and in a week "you couldn't have bought that horse for 100 dollars." Three cows were seen tied up in a barn "mourning for something." They were given half a bushel of Apples, which they eagerly consumed, and, ceasing their lamentations, took peaceably to their hay. Some interesting experiments to test the value of Apples for milch cows have also been made, and been entirely successful. The *Courant*, an American paper, says that "a large cow, something along in years," feeding exclusively on summer pasture, and producing four wine quarts daily, was, on the 1st of August, put on a diet of four quarts of Apples night and morning. The quantity was increased until, at the end of a week, she was eating a bushel of the hardest, sourest windfall Apples each day. Such was the effect of the Apples as to bring her produce of milk from four quarts to rather more than six quarts per diem. Another cow, by means of half a bushel of Apples night and morning, was induced to give a daily yield of twelve to fourteen quarts of milk. Similar experiments with other cows produced like happy results, and although in this country we have not Apples enough to make dumplings for ourselves, yet this plan of feeding cattle with Apples, and curing them of disease with that diet, is well worth the attention of rich owners of stock, to whom a heavy greengrocer's bill is a trifle; and young veterinary surgeons, who are at a loss for novelties, might make fortunes by starting the "Apple cure."

#### NOTES AND QUESTIONS ON THE FRUIT GARDEN.

**Standard Currants.**—In the fine old kitchen garden at Wollaton Hall, Notts, there are some fine specimens of standard Currants. The stocks are some 3 or 4 feet high, and I have seen them heavily laden with fruit of fine quality. They are very ornamental in appearance, and do not take up the space required by dwarf bushes of equal productiveness. When grown in this manner the borders below them can be planted with Lettuce, Endive, or other small saladings. This method of growing bush fruit is peculiarly adapted to villa gardens, where space has to be made the most of.—*F. W. B.*

**Pears and Plums for a North Wall.**—Will you be so good as to give me the name of two or three Pears that would succeed on a north wall.—*Tyro, Oxford.* [As regards Pears succeeding on a north wall, a great deal depends on the season. In warm summers I have grown *Beurré d'Ananas* for an early variety, *Louise Bonne* for mid season, and *Winter Nelis* for a late sort, with success, and their flavour has been good. *Beurré Diel* has succeeded with me and borne good crops even in bad seasons, which, if not fit for dessert, did very well for stewing. I should, however, advise "Tyro" to plant a tree or two of *Coe's Golden-drop Plum* on his north wall, for I find it higher flavoured when grown on that aspect than on any other.—*WILLIAM TILLERY, W. Beck.*]

## THE ARBORETUM.

### FOREST SCENERY IN BRITISH COLUMBIA.

Most people know that British Columbia is the country of the Douglas Fir, where that giant of the forest reaches its highest stage of development, rushing up to the amazing height of 250 or 300 feet. With us it sends out vast arms from the trunk, stretching far out on every side; there the branches are so short and closely packed in by surrounding trees that nothing but a close stifled congregation of stems is seen, with the foliage high up in the heavens, excluding the light and casting a deep gloom over the sunless vegetable mould in which the trees grow. In fact the common saying "one cannot see wood for trees" is literally true of such a scene so hemmed in is one by them on every side. But there is another aspect of these forests which is equally frequent and equally characteristic. One of the qualities of the Douglas Fir is that its timber forms excellent firewood even when green, and in dead trees the bark and wood are often so full of resin as to burn like a torch. Owing to this combustibility extensive forests of this tree get burned every year, taking fire from various causes. No doubt they often take fire from mere friction of the dead branches caused by the wind. Still oftener the carelessness of the Indians or white men originate them by leaving their camp fires unextinguished, not to speak of occasions on which for the most trifling causes the Indians originate them purposely and recklessly; lightning too adds to the number, and the volcanoes in some parts of the country (Mount Saint Helens and Mount Rainier), when in action devastate whole tracts in their vicinity by the burning ashes which they eject. When the Pacific Railroad exploratory party made its ascent of the Cascade range they passed for days through dead forests, which they supposed might have been burnt by ignition from this cause several years before; but large tracts were on fire at the same time, filling the air with smoke, so that they could not see the surrounding country for several days.

Similar scenes occur, from one cause or other, in all the great forests of Oregon, Washington County, and British Columbia. One who has seen them thus describes one of these fires:—"It is one of the grandest sights by night to watch the progress of the fearful element through the close-grown trees; the hissing of the flames enveloping the green limbs, the crashing of falling logs, and the clouds of belching smoke that darken the star-lit sky, the lurid glare and fitful light, in which the outlines of the hills and woods are seen starting from obscurity into view to sink again into thicker darkness. These, with all the minor concomitants of such a scene, make an impression on the mind which can never be effaced." The forest, long after the fires have been extinguished, wears a burnt aspect; but by-and-by nature reasserts her power. The dead trees fall, and they are succeeded by a growth of young trees, which rapidly rise to replace the old.

It might be thought that, however great the fertility of nature, and how unbounded soever her resources in that exceptionally favoured region, she could never keep pace with such constantly recurring destruction—where the growth of centuries is consumed in a few days or weeks—and it is undoubted, now, when the white man is one of the factors, that the end of these magnificent forests must come, and that these fires will bear their share in hastening on the event—but it is yet distant. The vast extent of these forests will yet bear a great deal of burning without its making any perceptible effect upon them. There is this important difference between the fires which take place in the forests in British Columbia and Oregon and those which occur in the prairies, and which run on for hundreds of miles in a straight line, that they are located in districts which are much intersected by mountains and streams; and though terrible in appearance, they are always circumscribed in extent, as the mountain spurs and jutting rocks, with the windings of the streams, form impassable checks to the most furious fire. The scene shown in the accompanying cut occurs towards the higher portion of a mountain, where the trees suffer more from fierce winds and cold than they do on the foot-hills or low grounds.

A. M.

FOREST SCENE IN BRITISH COLUMBIA.

## CONIFERS FOR GENERAL PLANTING.

Is there any valid reason why such a goodly number of the Conifers introduced of late years should be regarded as subjects only for the patch of dressed ground, and the immediate vicinity of the house, and be altogether ignored in the calculations of the general planter? We trow not. On the contrary, we are of opinion that many of them now sheltered and coddled, and fed with dainty pabulum, would find themselves much more at home if, instead of as domestic pets, they were treated as *feræ natura*, and allowed to take their place with the ordinary forest trees and their kindred Larch and Spruce, Scotch and Silver Firs, on moorland and mountain, hill and brae-side, glen and valley. In fact, it is only when they cease to be toys with the suburban amateur, who plants the giant Wellingtonia or the equally gigantic Sequoia, &c., in the expanse of turf some 10 or 12 feet square before his hall door, and when they are no longer looked upon by our country residents as merely ornamental evergreens, expensive to buy, troublesome to care, only to be sparsely dotted here and there in dainty spots about their dwellings, and form a percentage of all general plantings, that we shall get a true notion of their likes and dislikes, their marvellous development and economic value. Such of our readers as take an interest in planting, or know anything of tree lore, need not be told that but few of our ordinary forest trees are racy of the soil, or that the majority are aliens, and that, therefore, it may fairly be expected that at no distant day many of the recently introduced Conifers will, too, form no inconsiderable percentage of our woods and plantations. The rapidity of growth and timber-producing powers of many of the species recommended strongly to the notice of any one about to plant, either with a view to effect, shelter, or profit. The impression above alluded to, as well as that of fancied scarcity and high prices, act as deterrents and prevent many from even thinking of them who would set seriously about planting them if these impressions and fancies were once removed.—*Farmers' Gazette*.

## FORESTS AND RAIN.

A LATE number of *Nature* contained some clear and sensible observations on this subject, on which so much doubtful matter has been written. To what extent the climate of any portion of the surface of the earth can be changed by human labour is still an open question. Certain districts of the globe we are accustomed to look upon as condemned by Nature to perpetual sterility. The arid deserts of Africa and Central Asia, the frozen realms of Siberia, appear as if predestined to a gloomy lifeless solitude. To reclaim them to human control and human habitation may be one of the problems of the future. That climates have changed materially within recent times, we know as a historic fact. Macanlay has made us familiar with the damp fogs and perpetual rain-clouds with which our island was invested during the period preceding the arrival of the Danes and the Saxons. Much of the amelioration of climate which has since taken place is doubtless due to the increased cultivation of the land, and the extent to which the fen districts have been drained; but the main agent has probably been the destruction of the forests which then clothed a large portion of the island. The mode in which forests act in increasing the amount of moisture in the atmosphere is much misunderstood. Even in an article which recently appeared in the pages of so well-informed a journal as the *Pall Mall Gazette*, it is affirmed that this effect is due to the attraction exercised by trees on the rain-clouds. The principle by which trees act in effecting this is, however, at least mainly, by acting as pumps in drawing up the superfluous moisture from the soil. The most trustworthy experiments show that, under normal circumstances, plants have no power of absorbing through their leaves water, either in the fluid or gaseous state; their supplies are obtained entirely through their roots; and the superfluous moisture is evaporated from the leaves. The amount of aqueous vapour thus delivered into the atmosphere by vegetation is enormous, and has been the subject of careful investigations by French and German botanists. Von Pettenkofer recently detailed some experiments on the amount of evaporation from an Oak tree, made during the whole period of its summer growth. He found the amount to increase from May to July, and then decrease till October. The number of leaves on the tree he estimates at 751,592, and the total amount of evaporation in the year at 539.16 centimetres of water. The average depth of rainfall for the same period on the area covered by the Oak tree would be only 65 centimetres; the amount of evaporation is thus 8½ times more than that of the rainfall. The excess must be drawn up by the roots from a great depth; and thus trees prevent the gradual drying of a climate, by restoring to the air the moisture which would otherwise be carried to the sea by streams and rivers. The immediate result, therefore, of the diminution of forests in a thickly-wooded country will be to increase the proportion of the annual rainfall that is carried to the sea by the

natural drainage of the country, and proportionately to decrease the amount returned insensibly to the atmosphere, which then condenses into rain and cloud. Within certain limits it is obvious that this must be an unmixed good; but as the country becomes more and more thickly populated, and the land more valuable for habitation or culture, the danger rather lies in the other extreme, that the country will become so denuded of forests as to render the climate too dry for the profitable pursuit of agriculture. This has, in fact, taken place of late years to so great an extent as to demand the most serious attention.

## PLANTING TREES.

THE inducements to create property by tree-planting are so many and so powerful, that, to the greater part of those who possess the means, little, I hope, need be said to urge them to the employing of those means. Occasions enough will offer for showing how quickly the profits come. But, still there are some persons, who possess such means, who are well assured of the ultimate gain, but who are, nevertheless, discouraged by the thought that they shall not live to see the actual pecuniary product of their undertaking, and who, according to the idea of that dismal moralist, Dr. Johnson, begin to think of dying when they are exhorted to plant a tree. Let all such attend to the lesson given them in La Fontaine's beautiful Fable of the "Old Man and the Three Young Men," the wise, the generous, the noble sentiments of which ought to be implanted in every human breast.

Un octogénaire plantoit.  
 Passe encor de *butir*; mais *planter* à cet âge.  
 Disoient trois jeuneaux, enfans du voisinage  
 Assurément il radotoit.  
 Car, au nom des dieux, je vous prie.  
 Quel fruit de ce labeur pouvez-vous recueillir?  
 Autant qu'un patriarche il vous faudroit vieillir.  
 A quoi bon charger votre vie  
 Des soins d'un avenir qui n'est pas fait pour vous?  
 Ne songez désormais qu'à vos erreurs passées;  
 Quittez le long espoir et les vastes pensées;  
 Tout cela ne convient qu'à nous.  
 Il ne convient pas à vous-mêmes,  
 Repartit le vieillard. Tout établissement  
 Vient tard et dure peu. La main des Parques blêmes  
 De vos jours et des miens se joue également.  
 Nos termes sont pareils par leur courte durée.  
 Qui de nous des elartés de la voûte azurée  
 Doit jouir le dernier? Est-il aucun moment  
 Qui vous puisse assurer d'un second seulement?  
 Mes arriere-neveux me devront cet ombrage:  
 Hé bien! défendez-vous au sage  
 De se donner des soins pour le plaisir d'autrui?  
 Cela même est un fruit que je goûte aujourd'hui:  
 J'en puis jouir demain, et quelques jours encore;  
 Je puis enfin compter l'aurore  
 Plus d'une fois sur vos tombeaux.  
 Le vieillard eut raison: l'un des trois jeuneaux  
 Se noya dès le port, allant à l'Amérique;  
 L'autre, afin de monter aux grandes dignités,  
 Dans les emplois de Mars servant la république,  
 Par un coup imprévu vit ses jours emportés;  
 Le troisième tomba d'un arbre  
 Que lui-même il voulut enter:  
 Et pleurés du vieillard, il grava sur leur marbre  
 Ce que je viens de raconter.

To translate this is like an attempt to make a thing to resemble the rainbow; and, therefore, I beg those who may happen not to understand French, to be pleased to receive, from my pen, the following statements of the mere prosaic meaning of these words of this absolutely inimitable writer, who, in marks of simplicity the most pleasing that ever followed the movements of a pen, has, on numerous subjects, left, to ages unborn, philosophy the most profound and sentiments the most just and exalted.

A man of fourscore was planting trees. "To *build* might pass; but, to *plant* at such an age!" exclaimed three young men of the neighbourhood. "Surely," said they, "you are doating; for, in God's name, what *reward* can you receive for this, unless you were to live as long as one of the Patriarchs? What *good* can there be in loading your life with cares about a time which you are destined never to see? Pray devote the rest of your life to thoughts on your past errors; give up distant and grand expectations: these become only us young men!"—"They become not even you," answered the old man. "All we do comes late, and is quickly gone. The pale hand of fate sports equally with your days and with mine. The shortness of our lives puts us all on a level. Who can say which of us shall last behold the light of heaven? Can any moment of your lives seem you even a second moment? My great grand-children will owe shady groves to me. And, do you blame me for providing delight for others? Why, the thought of this is, of itself, a *reward* which I *already* enjoy? I may enjoy it to-morrow, and for some days after that; nay, I

may more than once even see the sun rise on your graves." The old man was right; one of the three, ambitious to see the new world, was drowned in the port; another, pursuing fame in the service of Mars, was suddenly stopped by an unexpected shot; the third fell from a tree, on which he himself was putting a graft; and the old man, lamenting their sad end, engraved on their tomb the story here related.—W. Cobbett.

**The Rose Acacia.**—Mr. Gordon could not have introduced to our notice (see p. 531, vol. ii.) a more beautiful plant in the form of a shrub than the Rose Acacia. Mongredien speaks of it as a "small tree," but I have never seen it anything like what could be called a tree. In the grafted form (in which I have only seen it), it never seems to "take" well on the stock, and I have seen many plants of it blown off at the graft. A short time ago I had to deplore the loss of a fine bush of it by the wind blowing it off the stock in that way. I have always taken it for granted that this shrub would not thrive on its own roots, and if any one has it growing on its own roots it would be interesting to know how it thrives in that way. This Acacia has a pretty effect on a wall, but it is in the bush form in which its grandeur is seen to most advantage, and I know of nothing that so well repays high culture as this plant.—CHAS. McDONALD, *Phoenix Park, Dublin.*

**Cinchona Cultivation in India.**—There are now 2,636,580 Cinchona plants in the Government plantations on the Neigherry Hills, without counting those of private planters. The largest trees are 30 feet high, and 3 feet in girth round the trunk. The area covered by the plantations amounts to upwards of 950 acres. During last year 7,295 lbs. of excellent bark were sold in the London market, realising prices from 2s. 3s. to 2s. 10s. the pound; and 35,072 lbs. were supplied to the local manufactory, making a total value of £1,600. While the original outlay for introducing this important cultivation in India will soon be repaid to the state with interest, hundreds of natives of India are annually cured by the quinine febrifuge manufactured from bark grown on the Neigherry Hills. The grand object of this beneficent measure has thus been attained, by the provision of an abundant supply of the febrifuge at so cheap a rate as to be within the means of the population at large.—*Ocean Highways.*

**The New Drug, the Eucalyptus globulus.**—Fever of a malarious character continues to prevail in the Mauritius, the extent of its prevalence as well as its severity varying much with the season—that is to say, increasing in the hot, and diminishing during the cold weather. We understand that the employment of quinine has been in a large measure discontinued in favour of the Eucalyptus globulus, which is considered by many who have watched its administration to have proved of real service, and a good substitute for the former very expensive alkaloid. The Mauritius offers, unhappily, a large field for testing the properties of this drug, and we shall await the results of further experience in that island with interest. At present there is only one tree in existence in the Royal Botanical Gardens, but the soil and climate of the Mauritius are very favourable to the growth of the Eucalyptus, and a large number of seedlings are thriving. The leaves are sold at sixpence an ounce, and an infusion of these is the popular method of administering the drug.—*Lancet.* [This tree grows rapidly over a vast area in temperate climes, as in southern Europe and California.]

## NOTES AND QUESTIONS ON TREES AND SHRUBS.

**Need of Timber Trees.**—People forget that while the supply of timber is limited the demand increases and accelerates the day of scarcity. At no very distant period, material for implements, ships, and building will be comparatively unavailable, and children may have very tangible reason for appreciating their father's wise forethought in planting trees.

**Evergreen Robinias.**—At the Lyons Horticultural Exhibition there were shown two Robinias, one by the firm of MM. Duroussat, and the other by that of M. Morel. They are both said to be evergreen, and if this be true, will prove valuable acquisitions for purposes of ornamentation.

**Conifers as Hedge Plants.**—I have read with much interest your account of Abies Canadensis as an evergreen hedge plant, and should be very glad if any of your readers would give their opinion of Conifers generally used for this purpose. I am trying Thuja Lobbi, Cupressus macrocarpa, common Yew, and American Arbor-vite, but it is too soon to report on their respective merits. The two last are, of course, too well known; but some correspondent may, perhaps, be able to say which of all the Conifers would in five years make the best hedge as regards graceful habit, colour, and denseness.—J. H. W. T.

**Lawns and Trees.**—Where shrubs and trees are so freely introduced as to balance in extent the breadth of turf, the lawn at once loses all character, and simply degenerates into mere bits of grass, dividing clumps of shrubs or isolating fine trees. The amplitude of turf should so predominate as to command and absorb attention independent of all other embellishment; and the finest of shrubs, and choicest and rarest of trees, should never intrude themselves, but appear in a secondary light whenever we come to those reaches and expanses of turf which are the glory of English gardens. Let these expanses of turf be held inviolate from shrubs or trees. Listen not to those who would talk about a fine tree in the middle or an Arancaria or weeping Ash "just to break the breadth of turf."—W. J.

## THE HOUSEHOLD.

### CELERY.

In the cold and dreary winter season in this country the choice of vegetables is somewhat limited, and would seem to call more than ever for the skill of the cook to make the best of it; yet such is the crudeness, so to speak, of British cookery, that it will not condescend to cook even the finest winter vegetable produced in these islands. Celery is generally served raw as an adjunct to cheese; and when they attempt to cook it, English cooks, for want of a bit of thread, send up a dish second only in unseemliness to the orthodox British greens. I do not wish for a moment to disparage the eating of raw Celery, which has considerable merits of its own; but I may be allowed to remark *en passant* that the practice of eating raw Celery is no better than that of eating raw green Artichokes or Tomatoes, and that I feel entitled to the sympathy of those who know how to eat for the sneers and the gibes I evoke when I point out the excellence of a salad of raw Tomatoes, or of a raw green Artichoke, young and tender, with that simplest of all sauces—oil, vinegar, pepper, and salt—good as it is simple. Raw Celery, cut up in convenient pieces, makes a very good salad, and can also be used with great advantage along with Olives, Beetroot, hard-boiled eggs, anchovies, preserved tunny fish, and sundry other things of the kind, to compose compound salads. Some of these have been, with questionable taste, dubbed with very grand names, as, for example, that of a celebrated adventurer of the last century, given by some professors to a salad of hard-boiled eggs and Celery, dressed with a mayonnaise and just a *soufflon* of Shallot; or the name of an equally celebrated actress, given to the same salad when Truffles and German sausage are added to it. In using Celery for these salads, or simply *à l'Anglaise* with the cheese, a considerable quantity of waste occurs; and it is the utilisation of this waste (the outside stalks, not the green leaves) of which I shall first treat.

The flavour of Celery, if judiciously employed, is a great improvement to many kinds of sauces and clear soups, down to the original stock pot itself, the *fons et origo* of all cooking operations. Now, the outer stalk of a head of Celery, if it is only duly washed, will impart the flavour just as well as the inner ones, or the heart of the said head; and if a sufficient supply of these outer leaves be at hand, Celery soup, clear, or thick, white or brown, can be made with them, while the hearts may be served with cheese *à l'Anglaise*, or made into a salad, or constitute an *entremet de légumes* in the manner that I shall describe further on. The common form of making clear Celery soup consists simply in boiling in some *consommé* a good allowance of Celery trimmings a sufficient length of time to give the *consommé* a strong flavour of Celery. It is then duly clarified with white of egg or raw meat, and served with a small quantity of the inner leaf of Celery, cut in small pieces of uniform size, and boiled in water with some salt and a little sugar. To make thick Celery soup I would take a quantity of the outer stalks of Celery, cut in small pieces, and boil them in salted water till quite done; then I would cut up an Onion and a Carrot in small dice, and fry them to a brown colour in butter, and, adding to them the Celery, I would stir the whole on the fire for a few minutes, moistening the mixture with stock; and, having duly seasoned it with pepper and salt, I would pass the whole through a hair sieve; then I would dilute the result with stock, and lastly, stir in off the fire a couple of yolks of egg, beaten up with a small quantity of cold stock and strained, serving the soup with small dice of bread fried in butter. To make thick white soup, the Celery should be boiled till tender in salted water, with a blade of mace, an Onion, and whole pepper; when quite done (the water being drained off), it should be passed through a hair sieve, and the pulp thus obtained diluted with white stock free from fat, the soup being finished by stirring into it, off the fire, the yolks of two eggs, strained and beaten up with a gill of cream. The following are two other formulas for making thick white Celery soup:—1. Blanch the Celery in water, then set it to boil, cut up in small pieces with some milk and a handful of Rice, previously boiled in water. When both Rice and Celery are boiled down to a mash, flavour with pepper, salt, and nutmeg; then pass the whole through a hair sieve, dilute to the proper consistency with white stock free from fat, and finish by either of these three methods. (a) Add a pat of fresh butter. (b) Stir in the yolks of two eggs, beaten up with a little milk or cream, and strained. (c) Stir in the yolks of two eggs, beaten up with a little cold stock, and strained. 2. Boil the Celery in stock. Melt a piece of butter in a saucepan, add to it half its weight of flour; mix the two well together; add the Celery and stock, with pepper, salt, and spices to taste; stir the whole well, and let it boil, then pass it through a hair sieve; add either stock or milk if necessary, and finish as explained above. Small dice of bread fried in butter are usually served with these soups.

Celery sauce is made exactly on the same principle as the above

soups, but it should be more highly flavoured and of thicker consistency, which latter result is easily attained by using a greater quantity of flour, that form being the best when a sauce, and not a soup, is to be made. That a well-made Celery sauce is one of the best adjuncts to braised and boiled poultry, and most white meats, hardly needs to be mentioned. A Celery sauce made still thicker merges into what is termed a *purée* proper, or in English might be called mashed Celery; and this also is a very good adjunct to cutlets or fillets of white meat, or may be served alone with fried sippets of bread round it, and eke a garnish of hard-boiled or of poached eggs. To so prepare Celery, less moisture as well as less flour should be used; and as for the flavouring, that remains the same, to be regulated only by the taste and skill of the cook—qualities which no directions of mine could possibly give that individual if she have them not. The common form for making a *purée* of Celery to be served as a vegetable would be as follows:—Boil the Celery in water with a bundle of sweet herbs, an Onion, whole pepper, a blade of mace, and salt to taste. When thoroughly done, drain all the water off, and pass the Celery through a hair-sieve. Melt a large piece of butter in a saucepan, add a little flour, stir well; then add the Celery pulp, stir the whole till quite hot, and serve. A little grated nutmeg may be added; and I may mention that a pinch of powdered sugar is not amiss in any of the foregoing preparations, all of which can be carried out with the outer stalks of the Celery. There is no reason, of course, but that of economy, why the inner part of the Celery should not be used; but if due attention is given to the proper washing of the stalks, and to the proportions of the flavouring, and, in fact, to the whole manipulation, no perceptible improvement will be gained by using the inner part.

Coming now to the cooking of this, I should first observe that the main reason why stewed Celery *à l'Anglaise* is so uninviting is, that each particular head is not properly trimmed and tied up as it should be. All the heads of Celery should be cut to the same length, and the roots trimmed all alike; then each head should be tied with a piece of thread (to be removed at the time of serving). Let no one cry out that this is unnecessary advice. I hope there are cooks in this country who know their business; it is not for them I write. I write for those who do not, and they are unhappily the majority. The simplest form of cooking Celery, when duly prepared as above, is to boil it in salted water with an Onion, a blade of mace, and some whole pepper; when done it should be carefully strained, freed from the threads, arranged neatly on a dish (not on a piece of toast—to my mind an abominable practice), and served with a plain sauce blanche, *i. e.*, melted butter into which have been stirred the yolk of an egg and the juice of a Lemon. Instead of this sauce may be used, sundry others, *e. g.*, Tomato, *Béchamel*, *Soubise*, *variogotte*, *poivrade*, *piquante*, &c. The next mode is this. The Celery is first parboiled, then laid in a saucepan on a bed of slices of bacon, with sliced Carrots and Onions, a bundle of sweet herbs, white pepper and salt to taste, a few cloves, and a blade of mace; enough stock is added to just cover the Celery, which is set to stew very gently till done; it is then dished up with a well-made Spanish sauce, or with some of the liquor it has stewed in, duly reduced, freed from fat, and thickened with butter and flour in the manner so often before explained. Another form of dressing Celery is to cut it in inch lengths, boil it in plain water till half-done, then to set it in a saucepan with any sauce you may fancy—white or brown—to simmer till done. Like the *purées*, this dish should be finished by the addition of yolks of eggs and Lemon juice, if the same be a white one, or it may be finished by the addition of a little cream, with or without the yolk of egg. Celery makes very good savoury fritters; but for this purpose it should be either boiled or stewed in the first instance, and, being cut into convenient pieces and well dried, dipped in batter and fried. Sweet fritters can also be made with Celery, which, for this purpose, should be parboiled first, then cut up and placed for some hours in a *marinade* of brandy and sugar, after which dip the pieces in batter and fry.

I have hardly left myself space to enumerate many varieties of which the preparations I have described are susceptible, but I will conclude with a recipe for dressing Celery with bread, which may commend itself to the lovers of the piece of toast that I so much deprecate. The proceeding is simple enough. Having parboiled the Celery, cut each head in half lengthwise, and stew it as directed above. When done, have some thin pieces of bread, cut in the shape of cutlets, and fried in butter to a light brown colour on both sides; dispose each piece of Celery on its *croûton*, arrange these in a crown on the dish, and serve with a well-made *sauce Espagnole*. The Celery served whole with a similar sauce, within a crown of these *croûtons*, each bearing a piece of beef marrow duly parboiled, makes a dish, if not quite fit for a king, yet sufficiently good for

*The G. C., in the Queen.*

## THE GARDENS OF ENGLAND.

### MILNER FIELD.

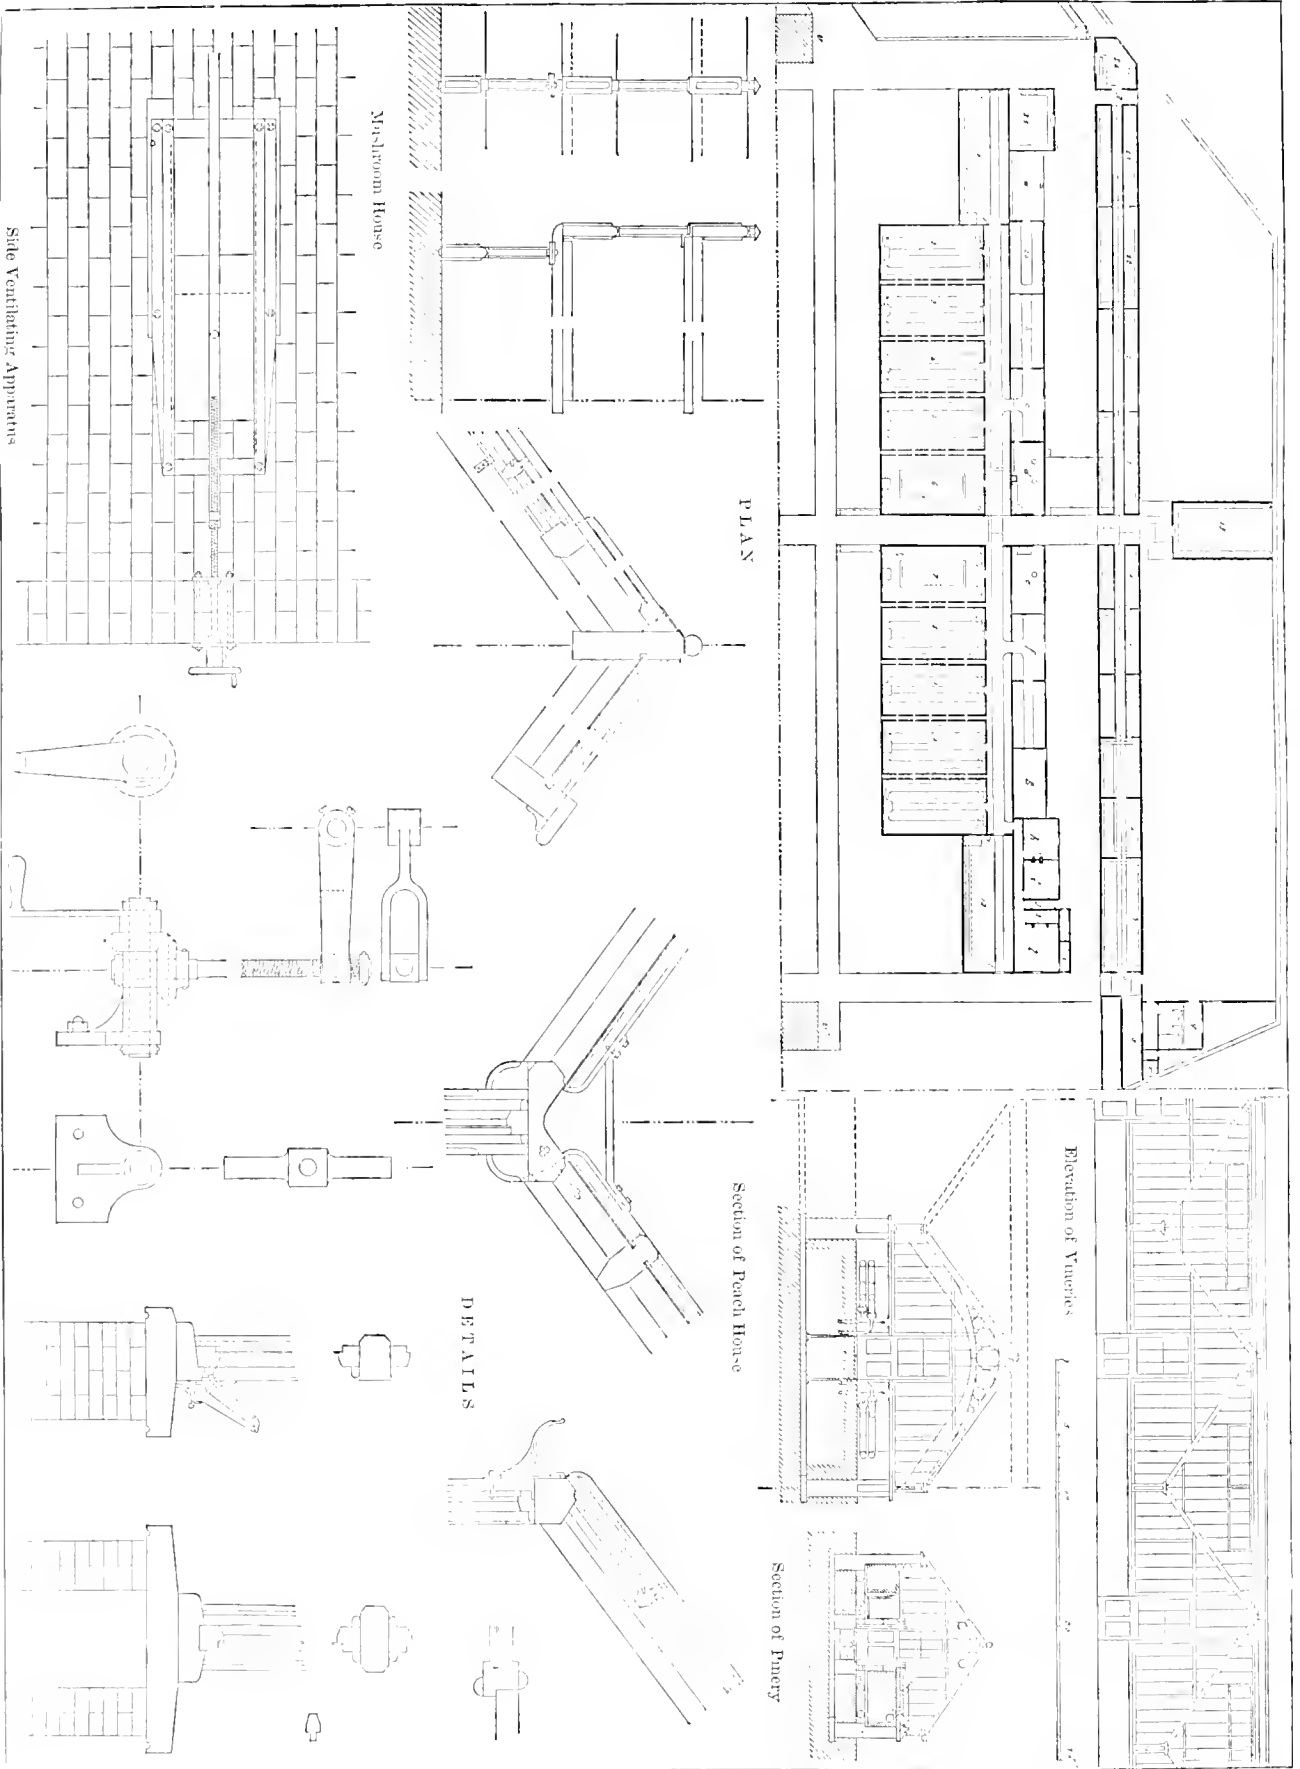

MILNER FIELD, Yorkshire, the seat of Mr. Titus Salt, is situated near the little town of Saltaire; and Saltaire, by the way, even from a horticultural point of view, deserves some notice at our hands, for, compared with the filthy manufacturing towns, familiar to us all, it is a fair garden. This wonderful creation of Sir Titus Salt's is well known to many, but we may nevertheless record that Sir T. Salt's determination to remove from the crowded town of Bradford, and to establish his vast works in an open, airy spot, has led him to form a town which could hardly fail to please even Mr. Ruskin himself, so free is it from the usual disagreeable marks of our manufacturing "civilisation" and "prosperity." Here it is shown clearly enough that manufacturing on a great scale may be carried on without necessarily disfiguring the face of the land, or being accompanied by conditions destructive to human life or health. The town, although a small one, is in possession of a pleasant little park, the gift of Sir Titus Salt, in which the shrubs and flowers seem to thrive as well as if 50 miles from a factory, as indeed they do everywhere in the town. The admirable club-house, presented to the workmen by Sir Titus Salt, and which cost him £25,000, and the other objects of interest in the place, we must pass by, and come at once to the subject of our present notice, which is seen pleasantly situated on the hills about two miles from the town.

Milner Field is a new garden—indeed it is yet in process of being laid out by Mr. Marnock, but enough progress has been made in the forcing department to permit of us speaking of it, assisted by the accompanying plans and details.

The principal houses are ranged side by side, lying due north and south; they are 34 feet long and 18 feet wide, inside measure, and are ten in number, and with lean-to houses at either end. All these houses open into a covered corridor, so that every house can be entered without exposing it to cold winds. The walks in the corridors are laid with 3-inch thick Yorkshire flags, and the paths of the houses are laid with cast-iron plates,  $\frac{3}{4}$  of an inch thick, and three feet wide, diamond pattern, supported on angle iron rails and cast-iron pillars every six feet; this arrangement leaves the border free for the roots of the vines, &c., to run under the paths. Out of each corridor opens a potting-shed, thus enabling plants to be carried into it without exposing them to the cold. The corridors are fitted up with tabling between the doors of the houses, for plants, and a high shelf runs the whole length, for Strawberries, &c.; the back walls are wired and ornamented with flowering creepers; one corridor with stove and the other with cool climbers. The houses Nos. 6 and 7 are fitted up with pits in the centre, and slate tables round, supported on angle iron rails and cast-iron pillars; the tables are covered with small cannel coal, which furnishes drainage for the pots, and has the advantage of not becoming green, as do spar and stone.

As to ventilation, the whole is worked from the two corridors by handles fixed on each side of the doors entering the houses, working by means of a pair of bevel wheels a perpendicular shaft with a double thread, which works into a nut attached to the levers for raising the top lights. These threads have all been cut in the lath, are  $\frac{1}{2}$  inch (double) pitch, and work very quickly and easily. The side ventilation is worked by means of a similar screw placed under the tabling, which opens and shuts sheet-iron doors into a ventilating flue in the brick wall between the houses, running to the outside; this arrangement is found to give ample ventilation. Nos. 2, 6, 7, and 11 have side light ventilation; the south lights in all the houses open if required; there is a rain-water cistern in every house, and a hot-water cistern (wood) in the boiler house, with a pipe through the wall and a tap in the corridor. This is of large size and supplies all the warm water for watering purposes. It is heated by a coil of hot-water copper pipes, so there is no fear of rust or other damage to the water.

As regards the heating, the whole of the houses are warmed by means of three of Weeks's patent duplex upright tubular boilers; one being only for use in an emergency. They are so connected that either one, two, or all three can be worked together, or any one will work the whole; and any one of them

PLAN AND DETAILS OF THE NEW HOTHOUSES AT MILNER FIELD.

can be used separately, either for the front or back range, as may be desired. The boilers are about 7 feet high, and are doing their work admirably. The main pipes are 6-inch ones, and run the length of each corridor, branching out into each house under the doorways. Each house has valves on both flow and return pipes, as have also the main pipes. The

valves used throughout are 2-inch, 4-inch, and 6-inch Pect's patent valves, and although costly in the first instance, they are certainly most complete.

The Pine and stove pits are made with malt-kiln tiles, about a foot square, supported on T iron bearers, an arrangement which necessitates a very small amount of bottom heat, and

works most satisfactorily. As these tiles seemed to us admirably suited for the purpose, we have had engravings made of them, showing a section and a view of each face. The warm air flows through the small holes, so that it is finely divided in the mass of soil to be heated. The Pines grown are principally Smooth-leaved Cayenne, Queens, and Charlotte Rothschild; and the fruiting house is now full of fruit promising to be of very large size, many being eight and nine pips deep.

The Vines planted are as follows:—No. 8, all Black Hamburghs; 10, all Muscats; 1 and 12, late Vines; 9, various.

The following references apply to that part of the plan which lies behind the corridor, viz.:—

a. Cart shed.	e. Tool and ditto.	i. Bed-room.	n. Larder.
b. Pot store.	f. Potting shed.	l. Living room.	r. Ashes.
c. Potting shed.	g. Vegetables shed.	k. Lavatory.	s. Cold frames.
d. Boiler house.	h. Bed-room.	m. Coal house.	q. Stable.

Mr. Salt has been his own architect and builder as far as these houses are concerned. The Mushroom house is fitted up entirely with stone and iron, and the work has been executed throughout in the very best manner. Everything is most substantial and complete, and seems thoroughly adapted for the purpose intended. The adoption of a plan by which all the largest houses open on to a roomy corridor much facilitates the labours of the gardeners, and permits the houses to be visited in an agreeable manner in any weather. This, or some similar plan, deserves general adoption. We hope to allude to some more interesting features of the gardens here at another time.

A TRANSATLANTIC contemporary describes a simple method of covering fresh flowers with alum crystallization. It is as follows:—Make baskets of pliable copper wire, and wrap them with gauze. Into these tie to the bottom Violets, Ferns, Geranium leaves, Chrysanthemums—in fact, any flowers except full-blown Roses, and sink them in a solution of alum of one pound to the gallon of water, after the solution has cooled, as their colours will then be preserved in their original beauty, and the crystallized alum will hold faster than when from a hot solution. When you have a light covering distinct crystals that cover completely the articles, remove carefully, and allow them to drain for twelve hours.

### EXPERIMENTS WITH COLOURED GLASS.

SOME interesting and instructive experiments have recently been made on this subject by M. Bert, and detailed in the *Belgique Horticole*, as follows;—I placed in large garden-frames filled with different coloured glasses twenty-five species of plants belonging to as many different families, including sun-plants (as Mallein, Milfoil, &c.), those growing in the shade (as the Violet, &c.), Grasses (Leeks, Cacti), green Cryptogams (Moss, Club-Moss, Maiden-hair), highly coloured red-foliage plants (Perilla), and Firs. The plants of each species were all of uniform size, and reared from the same seed. One of the garden frames was fitted up with ordinary glass, a second with white unpolished ditto, a third with well-blackened glass, a fourth with red, a fifth with yellow, a sixth with green, and a seventh with blue glass. Under the spectroscope, with a feeble jet of gas, the red glass was sensibly monochromatic; the yellow allowed of the passage of the entire spectrum, with a greater relative brilliancy in the yellow portion; with the green glass, the portions of the spectrum other than the green were extremely weak, particularly the blue and violet; the blue glass stopped all the rays except the blue and violet, the red being almost imperceptible. The frames were so placed as never to receive the sun's light direct, in which position they were—the yellow excepted—very nearly monochromatic. The operation of planting having been performed in advance, the frames were set on on June 20th. On June 24th I sowed in each of them several species of quick sprouting seeds, which appeared to spring up almost instantaneously. On July 15, the sun plants were dead in the black and green frames, very sickly in the other coloured frames, particularly in that with the red glass; all the other plants in the coloured frames were in bad condition. The mortality continued to increase. On August 2nd all the plants were dead in the darkened frame except the Cactus, the Lemna, the Firs, the Club-Moss, and Maiden-Hair, which were all very sickly. In the green frame all the plants were dead except the Geranium, the Leeks, the Celery, and the plants of the species still alone in the dark frame, but all of them doing very badly. The mortality was less in the red frame, and still less in the blue and yellow frames. The Perilla was dead in the black and green frames, and had lost all its red colour in the other coloured frames. An examination of the roots of the plants in pots showed that these organs were very slender in those in the black and green frames, less so in the red, fairly developed in those grown in blue and yellow frames, and very abundant in those in the frames fitted with white glass. On August 20th the situation had gained the mastery. In the black and green frames there remained alive the Acotyledons alone, and in a very sickly condition; in the red frames these plants were also sickly, less so in the blue and the yellow frames; as to the other plants, it seemed that the red had proved more detrimental than either the blue or the yellow. A close examination showed that the plants placed in the red light were much more elongated than those in the yellow, and in the blue more especially, but their stems were stronger. The grasses were more blanched in the yellow than in the blue; under the blue light the plants retained for some time their natural green tint, of a deeper shade than in those under the yellow frames, and a certain appearance of health withal. The seedling plants disappeared very quickly in the black and the green frames, and next in the red; in the blue frames they did better than in the yellow. I may add that in the frames with the uncoloured glasses all the plants continued to live and grow a trifle less vigorously under the unpolished than under the ordinary glass. Taking into account that the yellow glass was only two-thirds of the thickness of the blue, and that it allowed of the passage of rays of other colours than yellow, while the blue was monochromatic, we are led to the conclusion that—

1. Green is as fatal to vegetable life as the total absence of light. This is the conclusion I arrived at in the course of my experiments on sensitive films (see *Comptes Rendus*, vol. lxx., p. 388, 1870). The fact had been anticipated and explained before by M. Cailletet (*Comptes Rendus*, vol. lxx., p. 322, 1867). It is hardly correct to say that green light has no effect upon plants. I have found that the most strongly-heliotropic plants incline away from the green towards the red rays in their efforts to escape obscurity. 2. Red is a very injurious light, though less so than green. It produces a remarkable elongation of the plants. 3. Yellow is far less dangerous than the preceding colours, but more so than blue. If the plants lasted as long in the yellow as in the blue frames, it was due to the peculiarity above referred to. 4. Lastly, all colours, taken alone, are detrimental to plant-life; their union in the proportions constituting ordinary or white light is requisite to healthy vegetation, and it therefore behoves horticulturists to renounce the idea of employing coloured glasses or other coloured materials for glass houses and garden frames.

Now, if we examine light which has passed through a leaf with the spectroscope, we shall find that it is rich in red and green rays,

showing that these rays have not been absorbed by the plant. It is not surprising, therefore, that plants are unable to live when the only light we give them is that they cannot turn to account in the ordinary course of nature. To employ a forcible simile, it is like attempting to nourish an animal on the residua of its own digestive processes. But the chlorophyl in the leaves of different species does not allow of the passage of precisely the same coloured rays. Hence it is, doubtless, that, under the shade of a large Oak young Oak trees can only be reared with great difficulty, whilst Mosses and Ferns flourish; and under the shadiest bushes, Violets, certain kinds of *Neottia*, and other like plants, grow freely. In a word, I believe the associations of green plants living in each other's shade are chiefly determined by the coloured rays utilized by their leaves. This point will form the subject of a series of experiments, which I hope to be able to undertake in my immediate neighbourhood.

#### GERMAN HOTBEDS.

On these are placed frames covered with prepared cotton cloth instead of glazed sashes. Take white cotton cloth, of a close texture, stretch it, and nail it on frames any size you wish; mix two ounces of lime-water, four ounces of linseed oil, one ounce white of eggs separately, two ounces of yolk of eggs; mix the lime and oil with a very gentle heat, beat the eggs separately, and mix with the former. Spread this mixture, with a paint-brush, over the cloth, allowing each coat to dry before applying another, until the cloth becomes water-proof. The following are some of the advantages which these lights possess over glazed sashes:—

1. The cost is hardly one-fourth of that of glass.
2. Repairs can be easily and cheaply made.
3. They are light and afford shade.
4. The heat arising from below is equable and temperate, and the vapour arising from the manure and soil is condensed by the cool air passing over the surface, and hangs in drops upon the inside, therefore the plants do not require so frequent watering. If the frames or stretchers are made large, they should be intersected with cross-bars about a foot square, to support the cloth. These cloth-covered lights are just the things for bringing forward flower seeds in season for transplanting; and for forcing early Melons, Tomatoes, &c., prepared cloth is especially adapted, as it can be tacked to boxes of any size required, and cut to fit them. Little, rough, square boxes of the proper size and height, covered with the prepared cloth, can be placed over the hills in which Tomato, Melon, or other seeds are sown, and the plants allowed to stand, without transplanting, until all danger of frost is over, when the boxes may be taken off and packed away carefully for another season.—*Our Home Journal*.

[Some ten or twenty years ago transparent calico frames were much used in this country. They were made by stretching the calico on frames of any size, and giving them several coats of linseed oil, applied boiling hot. They were remarkably useful for a variety of purposes, such as sheltering bedding plants in the spring, wintering Lettuces, Endive, and Walcheren Broccoli; protecting shrubs for forcing, &c. They were also used for growing early Radishes and Potatoes, and Cucumbers and Melons, when the summer got further advanced. As glass became cheaper, however, they gradually fell into disuse. The cloth seldom lasted more than two or three seasons. A general opinion seemed to prevail that the oil helped to rot it, and a thin coating of glue or inferior isinglass was occasionally applied to form a sort of glazed surface over the oilcloth. Lime added would merely give greater whiteness, the eggs, of course, would form a glaze; but surely they would be better without the yolks, and it would be difficult to make the lime water and the oil amalgamate. Still translucent or semi-transparent cloth is useful for many purposes, and possibly that prepared on the German method may be as good or better than any other; but the advantages stated can hardly have been proved by experience. 1. The cost, instead of being set down as only one-fourth, should have been written one-fourth first cost; and even that is hardly true now, for it needs good calico, from fourpence to sixpence a yard, for making translucent cloth with any stay in it. Besides glass does not wear out, and calico does. 2. It is said that repairs are easily and cheaply made, which is, however, not the fact. Every patch lets the wet in, and the only efficient repair is a fresh cover. 3. To this I have nothing to say; but in regard to the fourth list of advantages, the last sentence is correct, viz., that these frames are capital for raising seeds. In fact, there are many purposes for which they are useful. During hot weather, however, the plants require as much care in regard to ventilation and watering as under glass; and the great danger of the so-called transparent cloths is the drawing of the plants under them. No textile fabric can be made as translucent as glass, and every degree of opacity left is a loss of strength and sturdiness to all such plants as Melons and Tomatoes.—D. T. FISH.]

## THE KITCHEN GARDEN.

### THE EGG PLANT.

I LEARN from a contemporary that fruit of this plant has been offered for sale in English markets, but from the description given of it, the variety must either have been a poor one or its cultivation could not have been well understood. I see no reason why this fruit should not make a useful item in mixed pickles, although I have not seen it used in that way; the size and shape mentioned, viz., 6 inches long by  $1\frac{1}{2}$  inch in diameter, would be a convenient size to cut up for that purpose, and would be of no use for cooking. This fruit, like its near relative, the Tomato, may be improved by selecting the best for seed, a fact of which I have taken advantage by saving the best each year, until I have obtained a very fine "strain."

I consider the fruit of this plant to be one of the most delicate additions to our very extensive list of summer vegetables; when nicely cooked it tastes more like Apple fritters than anything else with which I can compare it. Owing to the plant itself being much more tender than the Tomato, it is useless to plant it in the open ground in England; but it would succeed on hot-beds under frames, or, better still, planted in pits heated with hot water, so as to furnish a bottom heat of about 80°. It is a compact grower, and if cramped in pots or planted in close corners it would be smothered with red spider, and of course prove a failure. In America we sow the seed about the 1st of April, in a hot-house, prick off the young plants as soon as they are up, and pot them into small pots before the roots become much entangled, shifting once or twice, the last time into 6 or 7 inch pots. We keep them in a night temperature of 65 until the middle of May, and then harden them off by degrees until about the 7th of June, when they are planted outside. The ground being by that time well heated by the sun, they make rapid growth, and would astonish those who had only seen the starved specimens grown in pots as curiosities in English greenhouses. A dozen plants yield abundance of fruit for the supply of a large family. The only attention required after planting is to keep down weeds, and if the weather is very dry to give one or two good soakings of water. The hotter the weather the faster the plants grow. Here the soil is frequently over 100°, yet we think it necessary to plant our Egg plants in a sheltered spot exposed to full sunshine. The plants when young are very tender, so that if fumigation is necessary, they should be removed from the house, and if checked in any way red spider will attack them and soon spoil them.

J. TAPLIN.

*South Amboy, New Jersey.*

**Improved Dandelion.**—In the beginning of May, 1870, we sowed some seed of this Dandelion in a well prepared bed, in which the roots could easily develop themselves without meeting with any obstacle. The young plants soon appeared above ground, and in autumn we were able to cut from them great quantities of long and large leaves, which made an excellent salad. Others were cooked the same as Chicory (Endive), and were found to be very good. During the siege, ordinary Dandelions were sold retail in Paris at from three to four francs per pound. The improved variety is, however, so unlike the common kind, that each head of it might easily be mistaken for a large Batavian Endive, were it not for the colour, which is not the same. In winter we blanch wild Chicory in cellars, and in the bed in which it grows is also put the improved Dandelion, which produces leaves in equal abundance, and thus during the entire winter we are provided with blanched leaves of both plants, which are both wholesome and palatable.—M. BOSSIN. [This improved Dandelion was, we believe, sent out by MM. Vilmorin, of Paris.]

**Asparagus Flowers.**—Mr. Thomas Meehan, of Philadelphia, remarks, respecting the common Asparagus, that in consequence of observing last year so many plants that had evidently flowered producing no seeds, he had this year examined them in a flowering condition and found them perfectly dioecious. Imperfect stamens existed in the female flowers, but they were never polleniferous. An occasional gynoecium in the male flower would make a weak attempt to produce a pistil, but no polleniferous flower ever produces a fruit. There was a great difference in the form of the male and female flowers. The former were double the length of the latter, and nearly cylindrical, while the female flower was rather campanulate. Mr. Meehan added that this had a more than usual practical importance. Many attempts had been made to improve the Asparagus, as garden vegetables and the farm Cereals had been improved; but it had often been questioned whether these improved forms would reproduce themselves from seed as other garden varieties did. The

tendency of thought the few past years had been in the direction of the belief that permanent varieties could be raised, and several improved kinds had been sent out by seedsmen, and were popular to a considerable extent. He said he had himself inclined to this opinion; but this discovery of complete diacism in *Asparagus*, whereby two distinct individual forms were required to produce seed, rendered a true reproduction of one original parent impossible, as the progeny must necessarily partake of both forms.

## THE GARDEN IN THE HOUSE.

### *DIEFFENBACHIA BARAQUINIANA.*

This is the best species of an easily grown, handsome genus of stove plants. It is of moderate stature, and associates well with larger fine-leaved plants, or it may be intermixed with flowering plants in the stove; it is, however, a plant that does not stand well if kept long out of a warm, somewhat humid atmosphere. Consequently if it is taken out of the

*Dieffenbachia Baraquiniana.*

house or pit in which it is grown, it ought to be returned to its usual abode at the expiration of a few days. It is a free grower, and is not over nice as to the material in which it is grown. Either peat or loam, or a mixture of both, will suit it, to which add a liberal admixture of clean sand, with a little thoroughly rotten dung. Use plenty of drainage. The plant will stand a liberal shift, say from a 6-inch pot to a 10 or 12-inch one. It will grow well in the temperature of an ordinary stove, and it must never, even when comparatively at rest in winter, be subjected to a low temperature. At that season it will require 55° or 60° at night. It is a gross feeder, and will grow all the better if supplied occasionally with manure water; it is, however, best as a rule not to apply liquid manure to quick growing, succulent, variegated plants, as most of them do not come so finely coloured if grown too vigorously. This *Dieffenbachia* is not much troubled with the attacks of insects, but should they appear they are easily kept in check by an occasional application of the syringe. It strikes freely from cuttings made of short pieces of the stem, inserted in sand, and kept a little close until they have struck root. It likes a little

shade during the growing season, as its leaves are too soft to withstand the sun's rays when at all powerful. The beauty of its leaves makes it a desirable plant for room decoration, but it must not be kept too long indoors at a time, or it will fall into ill-health.

T. BAINES.

### CUT FLOWERS.

ASSUMING it as a principle that in a properly appointed greenhouse or garden no more flowers for the internal decoration of a dwelling house should be cut than can be well spared, it is, I think, important to know how to employ them in the most efficient manner, and so as to produce the best result with the least waste of material. Take as many flowers as you can hold in the palm of your hand and give them to one of the bouquet makers in Covent Garden Market, and she will in a few minutes produce you an exquisite bouquet; give the same flowers to persons of little or no taste and they would be thrown away as useless. And how will the bouquet-maker proceed? Well, there must be a foundation, and having selected her flowers, Violets, single bits of Geraniums, Heaths, Epacrises, and other things, she will fix them neatly upon small twigs of sufficient length, and having done that, so as to have two or three pieces of each colour, she will proceed to make a foundation. Now foundations are formed in various ways and of widely different materials. In the winter season, box or a few sprays of any other small leaved tree are taken and tied together so as to form a foundation of sufficient size, and then taking a Rose or Camellia for a centre she will proceed to arrange the other flowers around it in a light and elegant manner, and this the foundation, by keeping the flowers well apart, enables her to do. She will then edge with Mignonette or Sweet Briar, or perhaps with Lily of the Valley, and drawing in a small frond here and there of the Maidenhair or some other Fern, you will have a bouquet in which colour does not predominate over the greenery which ought to surround it.

In like manner give the same floral artist a vase of any size to fill with flowers. She will most likely throw in as a foundation a handful of Sweet Briar, and then taking Fern fronds or any other remarkable foliage, she will arrange it thinly but artistically. If she has any trailing plants they will hang carelessly from the vase, and the same with Fuchsias or any other pendent flowers; and then the colour will be lightly, but sufficiently used. Nature everywhere provides a sufficiency of green for her colours to be placed upon, and if we would do so in our artificial arrangements they would be much more effective. Why is it that the spring months are so much more enjoyable than summer and autumn? Not because of the change from winter, but in consequence of the coolness of the various tints of green; whereas, in autumn, we get the glowing colour of our corn fields and the matured leafage of the trees. Artistically considered, autumn is the most beautiful part of the year; but for coolness and quiet beauty commend me to a fine May morning. These general hints will be sufficient to show the difference between an artistic appreciation of the beautiful, and the want of it in the arrangement of flowers. Some years back I had some very elegant coloured glass vases, and in them flowers were not used at all—a drooping spray or two of Passion-flower, or some other elegant climbing plant, depended from the sides; and two or three branches of the Vine, with the foliage and tendrils complete, was all that was used; and these in the early part of the season were something really worth looking at. Bundles of flowers without foliage are very unsatisfactory; but elegant foliage with a few flowers, gracefully arranged in a vase or bouquet, forms an ornament not to be surpassed by all the art of the lapidary and goldsmith put together. P. A.

**A Parlour Window Garden.**—In our parlour window I have at present a delightful garden, consisting of a nice green-leaved Myrtle in the centre, on each side of which is placed a plant of India-rubber tree, and between these and the sides of the window two pretty plants of *Veronica imperialis*, bearing respectively eight and twelve expanded spikes of beautiful purple flowers. In front, next the glass, I have two elegant little plants of *Acacia lophantha*, and on either side a potful of Roman Hyacinths; then two nicely variegated-leaved silver tricolor *Pelargoniums*, and two pots, each containing four *Due Van Thol Tulips*, for both of which I paid a

shilling, similarly placed. In each corner is a potful of Ferns; I say a potful, for *Pteris serrulata* and *Adiantum cucuatum* are associated together. The whole is set in a framework of *Jasminum nudiflorum*, trained up both sides of the interior of the window, two branches being introduced from a plant grown outside through apertures made purposely for them. They are now laden with bloom in even greater profusion than the shoots outside, and they came into flower a fortnight earlier. The surface soil of the Myrtle, India-rubber tree, Veronica, and Acacia pots is covered with Club Moss (*Selaginella Kraussiana*) intermingled with some seedling Ferns. I flatter myself that I possess the finest winter garden I have yet seen, and one which passers-by enjoy quite as much as ourselves.—MARY S. WALLACE.

## WORK FOR THE WEEK.

### PRIVATE GARDENS.

**Flower Garden.**—The chief attractions belonging to outdoor gardens at present are winter Aconites, Jasmines, and Christmas Roses, together with a few miscellaneous flowers that have been tempted to expand, owing to the mildness of the season. Both evergreens and grass have also an unusually fresh look for this season of the year. Unless, however, cleanliness and tidiness are maintained, the most charming arrangement cannot be in itself satisfactory; therefore, in order to have a garden enjoyable, the roller, broom, and rake must be frequently at work. Use the hoe amongst growing plants, for a loose and open surface is congenial to their health. Prune deciduous shrubs, but the pruning of evergreens should be deferred until spring. All kinds of trees may still be transplanted, especially such as are deciduous. Proceed with any alterations that may have been previously determined upon. Any ground yet returned should be dug over as soon as practicable; if for Dahlias, Foxgloves, Hollyhocks, or other strong-growing grass-feeding plants, add plenty of manure; but if for Pelargoniums or other plants that are required to produce abundance of flowers and to keep dwarf in growth, a dressing of leaf-mould will be more beneficial. Lay up the ground quite roughly, in order that the frost, wind, and sun may ameliorate and sweeten it; well pulverised soil is greatly superior to that newly dug. Break up the surface of gravel walks, but not so deeply as to disturb the rubble in the bottom; and, if necessary, apply a coating of fresh gravel. Roll grass verges so that they may not appear too high above the gravel when cut.

**Conservatories.**—Use only fire-heat enough to expel damp and frost, and no more; and when for the former have some air on the house at the same time. Maintain a temperature of 40° at night, with the usual daily rise. Water all evergreen plants moderately, and keep deciduous ones nearly dry. Plants in borders require watering very seldom at this season, there being but little demand upon the roots at this time of year; but pot plants, especially such as are near hot-water pipes, require unremitting attention as regards water, for although apparently moist on the top the soil in the bottom of the pots may be dry. Such a condition would be extremely detrimental, as the greatest amount of roots is amongst and over the drainage. Rather than keep the conservatory too warm, in order to forward the plants therein, supply any deficiency there may be in the way of flowers by means of Camellias, Azaleas, Jasminums, Weigelas, Kalmias, Prunuses, Acacias, Dielytras, Lily of the Valley, Dutch and Roman Hyacinths, Tulips, Narcissi, Crocuses, and other plants from the forcing pit. Decaying leaves are unusually plentiful on greenhouse plants this season, therefore they must be regularly removed. A rather dry and healthy atmosphere is the only remedy for such an evil, and to effect this supply artificial heat and plenty of air; indeed, no good opportunity should be missed to ventilate freely, fire-heat being used at the same time, but avoid draughts. Keep Heath, Epacris, Chorozemas, Boronias, Tremandras, &c., in the coolest and freest ventilated portion; and forced shrubs and other flowers, Orchids, &c., in the warmest parts. Chrysanthemums done flowering cut over, and keep a pot of each kind in a frame, if sufficient cuttings have not already been obtained. Plant the others in the open border, or, if not wanted out-of-doors, throw them away. Shift herbaceous Calceolarias and Cincarias as they require it, and keep them cool and well watered; never permit a damped or decayed portion of a leaf to remain. Fumigate to destroy aphids, and keep in mind the old maxim, "prevention is better than cure." Keep Mignonette near the glass, and stake and tie it as may be necessary. Have a good succession of it in pits.

**Stoves.**—Maintain a temperature of 55° at night, and permit it to rise to 65° or 70° during the day with sun-heat. Plants of *Poinsettia pulcherrima*, whose beauty is past, should be removed to a dry corner and kept dry, but still in the stove. Plants of *Hexacentris* done

flowering, cut well back and induce them to go to rest. Give some weak manure water to *Eranthemum pulchellum*. Lay plants of *Lagerstromia indica* on their sides in a cool house. Plants of *Stephanotis*, *Allamandas*, *Passifloras*, *Clerodendrons*, *Cissases*, *Echites*, and other climbers, if required to bloom early, should be pruned, and syringed daily to encourage growth. The general stock of these, however, should yet remain at rest. Start a few roots of *Achimenes*, *Gloxinias*, *Caladiums*, and herbaceous *Gesneras* for early flowering; keep the majority, however, for later work and see that no damp comes in contact with them. Guard *Nymphaea* roots from the attacks of rats and mice; cats are the best and safest preventive against damage done by these vermin; and in order to encourage their presence a mouse or two should be given them in the place which they are desired to frequent; if that is done they will not fail to come again to look for more. Weasels are good friends to gardeners, and ferrets are useful for rat catching; with traps and poison and the other agents of destruction most of us are familiar.

**Indoor Fruit and Forcing Department.**—For fruiting Pines maintain a bottom heat of 80°, and a top temperature of 70° at night, and five or ten degrees less for succession plants. Pot suckers whenever obtainable, and keep the roots of all, except those swelling fruit, pretty dry. Begin forcing Figs with a night temperature of 50°, and thoroughly moisten the soil, for, if too dry, the young fruit is sure to drop. Peaches and Nectarines set their fruit much better if fire-heat and ventilation are given night and day during the time in which they are in flower, than they otherwise would do. Syringe the trees after the fruit has fairly set, and before the bloom has expanded, but not whilst they are in flower. Begin the forcing of Cherries with a night temperature of 45°, and give fresh air freely. Strip off the loose bark from late Vine rods, and apply a coating of some insect-destroying paint. Keep the unstarted houses as cool and airy as possible, and prune any Vines not already operated on. Syringe daily until the flowers begin to open, but not after that, for plenty of atmospheric moisture may be maintained by damping the floors and walls. Introduce into heat some Strawberry plants; 45° is sufficient at first, but if a bottom heat of fifteen degrees higher than that can be given, it would be an improvement. Continue to introduce successional roots of Rhubarb, Seakale, Asparagus, Mint, Dandelions, and Endive into the Mushroom house or hot-beds, where a temperature of 60° is maintained.

### NURSERIES.

Continue to pot off singly good rooted autumn-struck Azalea cuttings, but if neither time nor space can be spared for shifting them at present, leave them for a time in their cutting pots set on a side shelf of a close pit or intermediate house. Decapitate all long naked-stemmed Dracenas; use the tops as cuttings, and place the pots containing the stumps on the floor along the passage in close proximity to the pipes, so that the heat therefrom may more hastily promote the production of fresh shoots. The shoots can be taken off as they attain the length of an inch or two and used as cuttings. This method economises room in the heated plunging material, which should be saved for more delicate subjects. Any Statice becoming too long-stalked should have an incision made on each branch just at the base of the foliated crowns, after which some moss should be tied around it. The moss should always be kept damp, and if a little silver sand is mixed with it so much the better, as it helps to encourage root production. Keep old and young Statice moderately moist and in a minimum temperature of 45°. Decapitate tall plants of *Echeverias* and insert the crowns, no matter how large, in pots filled with good loam and a little silver sand, so that their base may rest therein without fear of being easily displaced. They soon emit roots and begin growing. Succulents of most kinds increase readily by means of leaves pulled off the plants, but in the case of those that produce side shoots abundantly, it is best to propagate by means of them, for in that case plants are sooner obtained. Pot off cuttings of *Libonias* and keep them for a short time in a warm pit, and when root action again begins, transfer them to an intermediate house. Divide the rhizomes of the variegated-leaved *Acorus javanicus* and keep the divided portions for a time in gentle heat. From male *Aucubas* in flower gather the pollen and keep it dry between bits of glass for future use. Start into growth in a warm pit tropical *Crimms*. Repot and start some *Hemantuses*; they may be placed upon the floor in a warm house or pit, or on a back shelf. Repot specimen *Dipladenias*, climbing *Clerodendrons*, *Bougainvilleas*, &c., and keep them dry for some time yet.

### KITCHEN GARDENING FOR JANUARY.

Should frost set in, all kinds of vegetables will doubtless now be found securely protected, as previously recommended for December, and the various kinds of protecting materials convenient and comfortable will be found at hand and in readiness for any future

emergency. Forethought, good system, and methodical application are the mainsprings of success in horticultural progress. We may naturally expect, after so much rain, severe frost, snow, hailstorms, and cutting winds for many weeks, when the application of protecting materials, more particularly abundance of dry dust, will be found invaluable. Examine all memorandums made of good and improved kinds of vegetables, and investigate all new seed lists at hand, selecting therefrom the most improved varieties and valuable kinds, which have been proved to be good. Look over the copies of your own seed lists for several years back, and select from them such old and good kinds of seeds as you have proved serviceable and true, never discarding a proved good thing till you are fully satisfied that you have found a decidedly better. Set about making out and sending in at an early season your seed lists, in order to give the seedsmen time to get the goods put up in proper order before the busy season arrives. Previous to this season's arrival of goods place any seeds left over from last year into drawers by themselves. Clean out thoroughly the drawers and cupboards, to be in readiness for the arrival of the new seed, and see that there is no chance for the encroachment of mice or beetles, and that all is dry and healthy, in order to prevent damp and mildew. Look over all the tools, which should always be found methodically arranged, and always put away clean in their places, and see to any repairs that may be required. The tothing of wooden rakes should be performed in wet weather by the garden boy or old man with tools consisting of a strong knife and iron punch made from a large nail with its point cut off or blunted, and a bundle of well-seasoned tough teeth made from sound ground Ash or other tough wood. Worn out tools replace with new ones possessing the last and most useful improvements. Select and wheel from the old hot-beds a good ridge of the cleanest decayed leaves for rotting into soil; also of the best rotten stable manure. Secure cow, horse, and sheep dung for the same purpose, and for converting into liquid manure. Collect and carry every kind of refuse to the manure or compost heap. Apply to it a good dredging of salt, and in turning it, freshly-slaked hot lime. If there be any weeds about, add them to the mixture. Manure and deeply trench up every bit of spare ground; cast it up into steep ridges 2 feet or 2 feet 6 inches apart, as roughly as possible, in order that the sun, wind, and frost can penetrate into the chinks and openings amongst the clods, to pulverise and sweeten them. This is the best means in practice of eradicating obnoxious insects, their eggs, and larvae. Deep trenching and forking and tumbling over the ridges with strong forks or pickaxes, when well frozen, is a famous way for keeping vermin in check; besides it is as valuable hereafter as a good coat of manure to the land. Deep trenching should not be performed on new ground in the first instance, for in the rank subsoil that has never before been exposed to the atmosphere, now cast up on the surface, nothing during the first season of exposure could be expected to thrive. Oh, no! Break up deeply and loosen well the bottom of every trench, to allow the free circulation of air and water to prepare its gradual admixture in advancing the depth of the soil in future trenchings. Thus, by such a process, well carried into practice for some years, any desirable depth of soil may be obtained and fully maintained. Forced roots of Asparagus, Seakale, Rhubarb, and Chicory are now fully in bearing. Continue introducing in due time into moderate heat a succession of roots, and commence to cover Seakale outdoors where it grows with leaves, stable manure, or such fermenting materials as will produce a gentle heat, and are convenient and comestible. Cauliflowers, Cabbages, and Lettuces of good kinds should be sown now in boxes or pans, in a little heat, such as the back of a frame, where Asparagus, new Potatoes, or Carrots are growing, or any place where a little warmth is at command, and prick them off an inch apart as fast as the plants can be handled, into other shallow boxes, pans, or pots. Place them under shelter until they are strong enough, and the weather favourable enough to prick them off, on some corner of a warm, sheltered border, or in a turf pit. Sow a small quantity of Celery on heat, and prick off as above. Never allow a check, but as soon as the plants are large enough plant them out on a gentle hotbed, covered with frames and lights, to grow on and be bleached for early use. Common wooden frames are always best for early Celery, because they can be so easily raised as fast as the Celery progresses, and owing to the Celery readily rooting down into the warm, decaying dung, and the applications at times of good tepid, clear manure-water, I have produced most beautiful blanched, crisp Celery in a very few weeks. Have under shelter dryish, sandy soil, or sea sand, and apply it on fine days for bleaching. The outsides of an early Celery bed should always be protected by mulching, otherwise the outside plants will make but little progress, while the middle plants will grow rankly. There is another evil or two to guard against in the production of fine, strongly-grown early forced Celery—first, if it gets checked, it

will start, or become pipey; second, if water is not methodically applied, it will get the canker, rot, and mildew, and red spider into its foliage. To grow it strong, crisp, and well blanched, it requires a kindly bottom heat and 6 or 8 inches of good, rich, well-pulverised, sweet soil placed on the dung-bed. The plants should then be placed on it by taking the seed boxes to the frames, and lifting them with their tufts of roots and earth adhering thereto, and planting them in rows crossways, from front to back. Keep all side snickers pinched or rubbed out as they appear. Surface stir between the plants, previous to the commencing of earthing up. Admit fresh air freely, water and earth up as required, and raise the frames previously to the foliage reaching the glass, to prevent crippling the foliage. If room enough is not given for the air to circulate freely between the glass and the foliage, the canker, or that most destructive of all pests, the aphid, will appear. By these means a supply of wholesome Celery may be had throughout March, April, and May, and every day in the year besides. In the three months named good Celery seems always scarcest and dearest.

Place in a little heat in succession Tarragon, Lamb Mint, and last year's roots of Sweet Marjoram. Sow Sweet Basil and Sweet Marjoram in a gentle heat, and prick off as soon as up. Sow Carrots and Radishes on a gentle heat in succession. Sow Peas and Beans on warm, well-prepared borders. Plant out in frames, pits, or beds, covered with hoops and mats, Potatoes previously induced to shoot in a gentle heat. Prepare more for succession also, and after the borders work kindly, and there is no fear of sharp frosts, commence planting out of doors. Peas, Beans, Lettuces, and Cauliflower plants, under shelter, or out of doors, on warm borders, or sheltered nooks and corners, may be kept sound and sheltered by the application of dry dust. Prepare, dig, screen, and cart to convenient spots, gravel in a fit condition for casing old walks, and making new ones, which should be performed when groundwork and cropping cannot well be done; and previous to the busy cropping season see that all garden edgings are evenly made up, the water-courses, drains, and gratings are all clear, and in clean working condition. Select new Pea-sticks, point and sort the old ones. Turn into tidy ridges manure and compost.

JAMES BARNES.

## OBITUARY.

### "THE STRAWBERRY KING."

WE regret to have to announce the death of the Rev. J. Knox, of Pittsburgh, Pennsylvania. Mr. Knox initiated a new era in Strawberry culture, overcame the many difficulties that barred his way, and thereby deserved well of all lovers of fruit. Twenty years ago, about which time he engaged in this business, Strawberry culture was conducted in a rude and careless manner; no one thought of the possibility and the profits of raising berries of which nine or ten would fill a pint basket. Following his example, thousands of growers were benefited by his industry, perseverance, and firm belief in thorough culture. Perhaps no one thing made Mr. Knox's name so celebrated as the "Juncanda" Strawberry, also called "Knox's 700." This was not altogether new to horticulturists; but, under Mr. Knox's system of cultivation, it improved so much that, for some time, it was not recognised as the old variety. Through his agency it became widely distributed, and with it the renown of the Strawberry King. The annual Strawberry exhibitions at the Knox Farm will be remembered by thousands of horticulturists and professional men from every State. It is safe to assert that nowhere more exquisite fruit has ever been seen than at these social gatherings. Every one present was not only gladdened by the generosity and liberality of the host, but took home with him a vivid picture of success in fruit culture. Mr. Knox was a true gentleman in the fullest sense of the word, and was one of the leading spirits of the pomological meetings for the last two decades. By his achievements in fruit culture, he has left a permanent inheritance to American pomology, and the thousands who knew him personally, or by his works, will keep him in grateful remembrance.—*New York Tribune.*

WE also regret to have to announce the death of Mr. James Donald, for many years gardener at Hampton Court, a situation to which he was appointed by Lord Llanover, then Sir Benjamin Hall, and which he has filled with so much credit to himself. Mr. Donald was fond of natural history and had a good herbarium, as well as a tolerable collection of geological specimens. His knowledge of British plants was extensive, so much so that when foreman in the plant department at Chiswick, some thirty years ago, he offered 6d. to any of the young men in the garden who would bring him a native flowering plant which he could not name. He had long been ailing, but at last died somewhat suddenly from heart and lung disease.

# THE GARDEN.

## A PROFITABLE PEACH TREE.

On the 3rd inst., I visited the gardens at Mauersa House, Roehampton Park, for the purpose of seeing a Peach tree there, of the productiveness of which I had heard good accounts. I saw it, and did not regret my journey, for I never beheld a more promising crop than it was bringing forward, even thus early in the season. We all know the uncertainty which attends the very early forcing of Peaches; but this tree has as fine a "set" of fruit on it as I ever remember having seen in March or April. Two trees are growing in the same house, which is 38 feet long and 16 feet wide; and both are equally productive, but the one referred to is the largest and consequently the most profitable. It covers a length of 20 feet, and was planted where it now stands eighteen years ago, having then been carefully removed from an outside wall, against which it grew and fruited for several years previously to shifting it indoors. It is a Royal George—a kind alike suitable for forcing and for general indoor and outdoor culture. Mr. Davis, the gardener, informed me that he has forced this tree every season for eleven years, during which period it only failed once to mature an excellent crop, which was in 1870, and that he attributed to over-cropping. For several years the fruit of this Royal George came first amongst Peaches into Covent Garden Market. On one occasion Mr. Davis sold the first dozen fruits to a fruiterer in his neighbourhood, who, not happening to find a customer for them, resold them to one of the principal salesmen in Covent Garden for the sum of £5. A few days afterwards another dozen was sent into the same market for sale, but this time only £3 could be obtained for them, the salesman adding, however, that he had sold the first dozen for £9.

Mr. Davis began forcing this season by shutting up the house on the 1st of November, an operation which might have been done if he had wished in October, so firm and ripe was the wood. The trees are planted inside the house in a border, the greater portion of which was removed and replaced with fresh turf about ten years ago, and whilst the fruit is swelling and the young wood growing it is deluged with sewage. The flow pipes run along between the trees and the glass and return along the centre of the house. Until the fruit has fairly set the night temperature is not allowed to be higher than 55° to 60°. The syringe is used freely from the time the house is shut up until the blossoms expand, when its use is entirely discontinued until the fruit has set. During the time the trees are in bloom air is admitted day and night, and fire-heat is given at the same time. Some gently syringe whilst the trees are in flower, but Mr. Davis does not do so, and success has attended his practice. Gently syringing expanded flowers may perhaps be practised with impunity in the case of trees that come naturally into bloom without forcing, but he has found it to be injurious to Peaches forced very early. When the fruit has set the ventilators are kept close at night, a damp moist atmosphere is maintained, and a good syringing is given every day by means of the engine with tepid water, and twice a day in fine weather. On my visit I found the house as follows, viz., fruit extremely well set, syringing again renewed, and disbudbing of the young wood commenced. Disbudbing and fruit thinning are energetically practised until the stouing period, when air is again left on night and day, and an equable temperature maintained. As soon as the fruits have stoned they may be forced as briskly as is desired and the final thinning performed. When ripe more air and a somewhat cooler temperature are again requisite for producing well flavoured fruit.

As soon as the fruit is gathered, instead of gradually lowering the temperature to correspond with that outside, forcing is continued. This matures and perfects the young wood sooner than it otherwise would be. When properly ripened, the house is gradually reduced in temperature until it is at last

laid open to all weathers, and the result is hard, well matured, properly developed wood, suitable for early forcing. The tree in question has suffered near the base from a disease that is yearly eating away its existence. Mr. Davis thinks it must ultimately succumb to this ailment. In order, however, to sustain life to the uttermost, he annually pares away all the dead portion and fills up the hole with a mixture of cow-dung and loam, held in its place by means of a piece of canvas and rope-yarn.

The following is a tabular statement of the dates of ripening, the amount of produce, and the sum realised for it during the past eleven years.

Date.	Fruit ripe.	Produce.	Sum realised.	Date.	Fruit ripe.	Produce.	Sum realised.
1862.	June 15.	42½ doz.	£12 10 0	1869.	April 29.	51 doz.	£60 0 0
1863.	May 28.	48½	48 10 0	1870.	May 3.	5	6 3 0
1864.	May 1.	42½	67 0 0	1871.	June 3.	74	37 0 0
1865.	April 21.	27½	65 0 0	1872.	May 1.	64	53 11 6
1866.	May 10.	38½	50 0 0				
1867.	May 3.	39½	49 17 0				
1868.	April 21.	37½	50 0 0				
						Total	473½ 4529 11 6

W. FALCONER.

## GARDEN HEDGES OF ROSES.

On visiting the gardens of the Right Hon. Lord Middleton, of Applecross, about the first week in August, I was much astonished to find a hedge of the Gloire de Dijon Rose over 200 feet long, and nearly 5 feet in height, and in the finest possible health, and one sheet of flowers—and such flowers! I was told by Mr. Whitelaw, the intelligent gardener there, that the idea of such a hedge originated with Lady Middleton, and that the idea was no sooner entertained than it was carried out; hence the result. Lady Middleton has also had a hedge of Sénateur Vaisse planted to the same extent as Gloire de Dijon, but more recently; consequently the plants have not the same fine appearance as the others. Those hedges are planted as screens to the kitchen garden, and nothing could be more appropriate; and, as Mr. Whitelaw remarked, there was no end of cutting Roses from them, which is another matter worthy of consideration where quantities of flowers are required. I may mention that before those hedges were planted a neat wire fence was put up, with five strands, and after the plants were put in they were fastened to the wires. As they grew, the shoots were intertwined in and out until they reached the top. By this means they are quite compact, and independent of any other fastening to the wires. The soil and situation here seem very suitable to the growth of the Rose, as the numerous dwarfs and standards were equally in fine health, and blooming in the greatest profusion. Applecross being situated on the west coast of Ross-shire, and nearly close to the sea beach, the influence of the Gulf Stream is sensibly felt; consequently there is but little frost in winter. Tea Roses, Fuchsias, &c., are seldom injured; in fact, Fuchsia Riccartoni is quite a shrub here.

J. DOWNIE, in *The Gardener.*

THE French papers describe the results of the present high temperature as something very unusual. Even in Paris the leaves are beginning to show themselves, and several spring flowers have appeared. Raspberries have ripened in some of the Southern departments, and a field of Asparagus is in full bearing at Larçay, in Indre-et-Loire; while at Orleans those who are fond of the cruel sport may, if they please, spin the early village cockchafer. At Perigord, near Toulouse, Almond trees have been in full blossom out of doors for these last eight days.

If the season of the year has been characterized by an unparalleled rainfall, it has also been remarkable for its extreme mildness. A handful of Violets may be gathered in a few minutes in the hedgerows in the neighbourhood of Haverfordwest, and in sheltered situations fruit trees are almost bursting their buds. We have seen this week, in a niche in the wall of Foley House, in a most exposed situation but partially screened from the wet, a quantity of zonal Geraniums with scarcely a ragged leaf or blighted limb. They seem to be enjoying their summer quarters now as well as they did in August. At Wierton House, Maidstone, the following flowers and shrubs have been in bloom during last month and this, viz., Tea, China, and Perpetual Roses, Veronice, Fuchsias, Chrysanthemums, Picotees, Calcceolarias, Violets, scarlet Geraniums, Antirrhinums, Gladiols, Hollyhocks, Pyrethrums, Lavender, Schizostylis coccinea, Christmas Roses, Arbutus, Jasminum nudiflorum, Leycesteria, Escallonia macrantha, Gentianella, Primulas, Polyanthus, Hepaticas, Snowdrops, Wall-flowers, Phlox verna, Ceanothus azureus, Cydonia japonica, Myosotis dissitiflora, and various Anemones. Camellia blooms have also been cut from the open air, in the neighbourhood of Maidstone. Hazel catkins, in a very forward state, have likewise been received by us from Mrs. Harrison, The Avenue, Beckenham, Kent.

## NOTES OF THE WEEK.

— WE have just seen evidence that the brilliant Gentian-blue *Lithospermum prostratum*, so valuable in our rock gardens and borders, is a very good subject for forcing. It is easily brought into bloom, and being distinct in habit and colour from anything used in early forcing, will prove a great boon for winter and early spring decoration.

— THE largest flowered forms of *Cyclamen persicum* which we have ever seen were shown by Mr. Clark, of Twickenham, at the last meeting of the Royal Horticultural Society, at South Kensington.

— MESSRS. RIVERS showed a good collection of Oranges the other day at South Kensington from trees growing in cool houses. The flavour of the fruit is usually so much finer than is that of the ordinary imported fruit that the Orange is well worth growing in our cool houses for the sake of its fruit alone. It of course merits this also for the sake of its flowers.

— MR. W. SAVILE KENT, of the British Museum, favourably known for his biological and zoological researches, has been appointed curator of the Brighton Marine Aquarium, in succession to the late Mr. Lord.

— NOT only are fine dessert Apples, like the Newtown Pippin, now coming to us from America, but also kinds used in cookery. Mr. G. F. Wilson showed specimens at the last meeting of the Royal Horticultural Society of a dozen varieties or so of American cooking Apples in fine condition; they were purchased in Liverpool. Such supplies have greatly helped to mitigate the dearth of fruit that has existed this year at home.

— EVER since variegated Kales have been used for decorative purposes at Wardie Lodge they have been planted for ornament more or less not only in Scotland, but also in England, and very effective they are where good kinds are employed. A correspondent signing himself "Argus" writes thus respecting his ornamental Kales:—"Never," he says, "have I seen them so lovely as they are this year. The snow whites, rich crimsons, and other hues contrast and light up the quarter in which they are planted with as much beauty, even at this dull season, as is to be met with in our summer gardens. But I must add that there are few of the stocks of variegated Kales that are worth growing, and I hope that the attention of some of our seed growers may be directed to this matter. I have grown Kales for years, and have had supplies from many sources, but have always been disappointed until this year, when their beauty is undisputable."

— THE loveliest sight which we have seen for months in the vegetable kingdom was that presented by a mass of the roseate *Bougainvillea*, sent from Ashridge Park to Kensington on Wednesday last. The branches of gloriously-coloured bracts were as fine as ever we remember to have seen them, and at this dull season the house in which they grow must be well worth a visit. The specimens were grown by Mr. Gray, the flower gardener at Ashridge.

— BARONESS BURDETT COUTTS, having observed that a meeting was to be held at Hackney, under the presidency of the Lord Mayor, for the purpose of securing the conservation of land, not only in the east of London, but throughout the metropolis, for recreation and enjoyment, has spontaneously forwarded to Mr. F. G. Heath, the Hon. Secretary to the Victoria Park Preservation Society, a cheque for £25 towards defraying the expenses of the movement. In order to guard public property everywhere about London from builder's and other encroachments it was resolved at the meeting in question that an association be formed under the name of the "Park Preservation Society," and that a committee be selected to carry out the necessary details. Epping Forest, it was stated, not many years ago contained some 7,000 acres; now there were but 3,500. It was, therefore, considered to be high time to band together in a legitimate manner for the assertion of the people's rights.

— SOME curious statistics respecting the importation of Potatoes are given in an official document just issued. In the month of December, 1870, the value of such importation was only £146; in the same month of the succeeding year the amount was £33,770; and in the month of December last it reached £343,367. In the year ended the 31st of December last the amount was £1,654,240 against £225,732 in the preceding year.

— IN memory of Professor E. Forbes, the learned Manx naturalist, will shortly be published, a "Flora of the Isle of Man," illustrated with engravings of the principal island scenery (waterfalls, &c.) and accompanied with an actual specimen of the Manx Fern (*Adiantum Capillus Veneris*) mounted as a vignette. Besides a list of the flowering plants known up to the present time, with localities and interesting notes of the species, a detailed description of all the indigenous

Ferns and trees will be given, together with an introduction of botanical rambles through the island, the folk lore of wild flowers, and Life of Professor Forbes. An appendix will accompany the volume, describing a new method of nature printing, the art of preparing skeleton leaves, making screens with leaves, &c., especially adapted for ladies, thus providing intellectual amusement and occupation for the winter months, and as far as possible making a thoroughly readable and interesting volume. It is to be hoped that all lovers of British botany, especially friends of Professor Forbes, will cheerfully come forward and aid the author, Mr. James F. Robinson, Frodsham, Cheshire, in bringing out the first edition, the price of which to subscribers is not expected to exceed two shillings and sixpence.

— STRAWBERRIES were sold in the streets of Rome on New Year's Day, and gardeners have picked Peas grown in the open air.

— A VERY strong proof of the mildness of the season may be found in the fact that the Bristol and Exeter Railway now carries daily from Cornwall about 200 tons of Broccoli.

— MR. PEACOCK, we learn, has just received a new *Opuntia* from Texas. It is in the way of *O. Rafinesquiana*, but the spines are very dense, and 1 and 2 inches long, dark brown at top, and pale below. It is said to be perfectly hardy, to grow prostrate, and to be a very pretty species.

— WE understand that, on the occasion of the Emperor's funeral, on Wednesday last, Holly, Yew, and other trees growing in and about the little churchyard at Chislehurst, in which his remains are placed, got sadly mutilated, such was the eagerness of the crowd to carry off some memento of the sad event. Even Snowdrops in bloom on neighbouring graves were not spared.

— PINE APPLES at all presentable at this season used to be rare, but now, thanks to our leading growers, they are becoming quite common. The fruit exhibited at South Kensington on Wednesday last by Mr. Miles, gardener to Lord Carrington, were simply magnificent. At Midsummer such fruit would be a credit to any grower, but in *mid-winter*—and such a winter!—they were beyond all praise.

— A BEAUTIFULLY bloomed plant of *Crassula lactea* has just been shown to us by Mr. Thomson, of Penge, who finds it to be a favourite with people who are fond of winter flowers, and yet have nothing better than a window or cool greenhouse in which to grow them. It is a fleshy leaved plant, which, though not more than 9 inches in height, bears a profusion of branching spikes of pretty white star-like flowers that last long in perfection. Belonging as it does to a family whose head quarters are at the Cape of Good Hope, it is, of course, not absolutely hardy; but it will nevertheless stand a good deal of hard treatment, and as a winter-flowering window plant has few equals at this season of the year.

— GRONINGEN, in the north of Holland, is a province almost entirely devoted to the culture of Potatoes. It appears that the district possesses thirteen mills which are said to be constantly at work converting nearly the whole of the Potatoes grown there into flour, of which 250,000 kilogrammes (about 246 tons) is produced per day. Thus far no one in this country has any right to object, but the journal proceeds to remark that the greater portion of this Potato flour is exported to England to be used in the manufacture of bread. Now we admit that Potato flour is a very good thing, but wheaten flour is a much better thing for food, inasmuch as the latter produces nearly five times the quantity of nitrogenous, or flesh-forming material, and nearly three and a half times the carbonaceous or heat-yielding matter as the former. It seems evident, therefore, that used in the manufacture of pure wheaten bread, Potato flour becomes a flagrant adulteration; and, if all the Dutch journal states be true, the sooner this monstrous fraud is looked into by our authorities the better.—*Food Journal*.

— OUR old friend *Punch* is quite delighted at the sight of his own shadow, cast during the recent sunshine, and we must confess that there is more common sense in his ecstasy than in the wretched twaddle lately bestowed upon gardening matters in "Happy Thoughts," by our facetious contemporary. The following is one of the least silly of the passages to which we allude:—"The new Currant bushes are tied on to the tops of the highest trees, looking very like those Dutch brooms which a landsman often notices with wonder at the mast-heads of fishing smacks. The Celery beds are completely dug up, looking like a troubled sea in dirty weather, with the exception of one small patch in the centre, where we observe a stone jar standing, labelled legibly 'Mixed Pickles.' Garden tools, all brand new, which he has bought on his own account, are, we see, planted out in a row, like young trees, and carefully propped up. An empty milk-pail is by the Strawberry beds."

THE INDOOR GARDEN.

SACCOLABIUMS.

THESE most charming of all Orchids come from the hottest tropical regions of the world, and when well grown form fine specimen plants of the most attractive description. To cultivate them successfully, however, they require a hot and humid atmosphere, together with many other tropical Orchids from the old world, which revel in heat that would soon be fatal to the pseudo-bulbous plants from the higher ranges of the new world. They are mostly natives of the continent of India or the Malayan Archipelago, where they luxuriate, bathed in tropical showers and warmed by the invigorating power of a tropical sun. In cultivation they grow best in fresh fibrous peat, charcoal, and crocks, the whole being surfaced with clean fresh living sphagnum. When making their growth they must be liberally supplied with moisture, and a frequent use of the syringe must be resorted to, which will keep them in a healthy condition and less liable to the attacks of that bane of Orchid growers—yellow thrips—than they otherwise would be. The syringe, when properly used, is a valuable aid to the successful culture of all Orchidaceous plants. A skilful Orchid grower may syringe his plants with advantage summer and winter, while many a less able culti-

Saccolabium guttatum.

vator might inflict a permanent injury by being entrusted with this useful implement. In dull weather, when there is but little light, and when growth is nearly, if not quite, at a standstill, the syringe should be used as a vaporiser, letting the water descend on the plants like fine dew, so as not to run into the crowns or trickle down the channelled leaves into their axils. This is easily done by placing the forefinger carefully over the nozzle or jet when syringing. By this simple precaution the water can be distributed far better than with the finest rose. If kept free from insects—thrips and brown scale—and grown in a warm temperature, which should not fall below 60° in winter, Saccolabiums may be grown well and flowered freely.

The following species, which are considered to be the best belonging to the genus, are in general cultivation:—

**S. AMPULLACEUM.**—This is an Indian species, which is rather dwarf in habit, bearing dark green leaves, which are sub-erect and distichous. The flower-spikes are produced very freely during the summer months, three or four erect spikes being borne on a plant 6 or 8 inches in height. The flowers are of a bright rosy purple colour, and last in beauty a fortnight or three weeks. This plant grows remarkably well in living sphagnum and crocks, in a shallow basket or pan, suspended from the roof, near the light. There are some fine plants of this species in Mr. Dawson's collection at Meadowbank.

**S. BLUMEI.**—This is a distinct and well-known species, from

Java, having rather narrow leaves of a pale green colour, with darker lines below. It sports into one or two finely coloured varieties, and bears pearly flowers, spotted and blotched with rosy lilac or violet. It generally blooms in autumn, and lasts a fortnight or three weeks in perfection, if the flowers are kept from drip or superfluous moisture. *S. Blumei majus*, *S. Blumei Dayi*, and *S. B. Russellianum* are all considered by cultivators as superior varieties.

**S. CURVIFOLIUM.**—This is a very distinct species, found in Nepal and Ceylon, and easily recognized when not in flower by its light green, gracefully arched foliage, which is sometimes spotted with purple or brown. Its blossoms are orange scarlet, varying to pure yellow in different varieties. It is a desirable little plant, and does well in a basket or pot.

**S. GIGANTEUM.**—This species, which comes from Burmah, is one of the finest of the whole group, having very stout broad foliage marked with parallel dark lines, as in *S. violaceum* (*Vanda violacea*). Its flowers are large and of great substance, and arranged very thickly on stout tapering spikes. Some varieties are remarkable for the dense violet colour of the lip. It is very fragrant and lasts from three weeks to a month in beauty. It blooms in the spring and grows well in a cork basket or pan suspended from the roof.

**S. GUTTATUM.**—This species, which has been found in Nepal, Java, Sylhet, and Malabar, is a lovely and very profuse flowering kind when well grown. The habit is something like that of *S. Blumei*, but the leaves are darker and not so definitely marked with dark lines. The flowers are pure white spotted with rosy-purple or lilac, and are borne on gracefully pendant spikes, as shown in the accompanying illustration, which gives a fair idea of the superlative beauty of this plant when well flowered. The blossoms are of a wax-like consistence and most deliciously perfumed. It makes a fine exhibition plant when well established, and was exhibited some years ago with between twenty and thirty spikes on a plant. There are several varieties of this species, which differ from each other and the normal type either in the colour of the flowers or in the width of the foliage. They last from three weeks to a month in beauty.

**S. VIOLACEUM.**—This old Manilla species is well worth culture on account of its flowering during the winter months. It bears numerous short dense spikes of white and violet flowers, and lasts a month in perfection.

There is a white variety of *Saccolabium* called *Holfordianum* by growers, which is well worth having in the most select list. There are about half a dozen more species in cultivation, but all the above are select kinds well worth growing in all good general collections. F. W. B.

DOUBLE-FLOWERED TABERNÆMONTANA CORONARIA.

THIS is a native of the West Indies, and, though an old inhabitant of our gardens, it is now rarely seen in anything like good condition. A quarter of a century ago it formed a leading exhibition plant. Its flowers, though smaller, are not unlike those of a *Gardenia*. They are pure white, are produced in bunches of from two to five, and are sweet and admirable for bouquets. The plant is a very free-growing one—when it gets suitable soil and plenty of heat—but still it is not an easy matter to produce a dwarf, compact, well furnished specimen. It is readily propagated by cuttings of the half-ripe or mature wood, though the first is preferable; and the best plan is not to trim the cuttings to a joint in the usual manner, but to cut them at 2 inches long, so that the growing buds may be brought as near to the surface of the soil as possible. Put them in either singly in thumb pots, and, after plunging in a brisk bottom heat, cover with a bell glass; or put them ten or twelve in a 4-inch pot, and then cover them. A mixture of peat and loam with some sand, surrounding the cuttings with sand, will be the best medium in which to strike them. When properly rooted, which will be in about six weeks, inure them gradually to the air, and then begin to grow them on. The best compost to grow them in will be found to be two pecks of rich fibrous loam from which the fine soil has been removed,

half a peck flaky leaf-soil, peat the same quantity, with a quart each of crushed charcoal and sand all thoroughly incorporated together. If the newly struck plants are vigorous and well rooted, they may be removed at once to well-drained 4-inch pots, sinking them so as to bring the branches close to the soil. Pot firmly, and if afterwards the plants can have the benefit of a bottom heat of 80° to 90°, they will be all the better for it. This will start them into vigorous growth, and the side shoots will make rapid progress. The atmospheric temperature necessary to the best results will be a mean of 70°, rising to 80° or even 90°, with sun heat on bright days, and with plenty of atmospheric moisture. When the pot is full of roots, reduce the supply of water for a week or so, and place the plants close to the glass, so as to ripen them a little, then cut the shoots back to within two joints of the base, and, instead of two, you will soon have four, six, or more shoots. In this way you get what may be called a foundation for your specimen, and then the plants may be allowed to grow on for the remainder of the season. After they have been stopped, and begin to grow again, the plants may be moved to an 8-inch pot, using the same compost, and continuing the treatment as to heat and moisture. If you want the young plants to bloom, that object must be effected by attending to the ripening process early in the autumn. The growth must be brought gradually to a standstill, and then, by free exposure to full sunshine, the wood must be thoroughly matured. This effected, the temperature of an intermediate house, 50° to 60°, will be sufficient through the winter, and the season of blooming may be governed by the time at which you introduce the plants to a brisk growing temperature. If, however, the object is to make a handsome specimen, blooming the second season must not be thought of. Instead of that, cut your plants boldly back in February, and as soon as the young shoots make their appearance take the plants out of the pots, remove such of the old, inert soil as you can without destroying the roots, and then pot them on into pots of suitable size. The same summer treatment as to bottom heat, and a brisk growing temperature may be continued, but at the same time the plants must have all the light possible, so as to induce a short, stubby growth, and hence rampant shoots may be stopped with the object of getting side spurs; but this stopping must not take place later than the end of July, or the growth will not be matured. If these directions are attended to, the end of the second season of growth should show a plant that will furnish handsomely a 12-inch pot; and once formed, the plants will continue to grow steadily for many years. With established plants the only care necessary is to stop rampant growth and encourage the formation of spurs; for, as the plants bloom from these small shoots, one cannot have too many of them. I have omitted to mention that weak manure-water may be given when the pots are full of roots and the plants in free growth, and also at the time when the blossom buds are swelling. The plants are subject to the attacks of insects, which must be subdued in the usual manner. A.

### THE HEMANTHUS.

This is a genus of African bulbous plants belonging to the order Amaryllidaceæ. They are easily managed, and many of them produce large and highly-coloured umbels of bloom; and yet there are now but few people who either know or grow them. Twenty years ago these plants were highly prized, especially in one situation in which I was employed, where we used them extensively, and found them extremely serviceable at two particular seasons—viz., in early spring and end of summer. Those flowering in spring were of course forced, and in this way they were easily managed; whilst the late summer flowers came naturally, and were most useful, for all gardeners and amateurs know that just at the end of summer there is usually a great paucity of bloom in the conservatory, and these then become doubly valuable. I have frequently heard the objection raised that they are ugly because they flower without leaves, and there is something in this objection; yet it should not deter lovers of plants from their cultivation; and, moreover, all the species are not leafless at the blooming time. When I used these plants extensively, my remedy for this want of leaves was a very simple one, but nevertheless so effective that it could be adopted by any and every one. When the bulbs were brought out from their resting-places and induced to send up their scapes, some seedling Ferns

were pricked into the soil tolerably thick, and as these grew up they always produced sufficient leafage to back up the gay-coloured blooms, so that the absence of their own foliage was not missed. A proper selection of Ferns should be made for this purpose, by which I mean good, free-growing, robust-constituted kinds, such as *Doodia caudata*, *Adiantum cucucatum* and *A. hispidulum*, *Asplenium bulbiferum*, *Blechnum occidentale*, *Lastrea decomposita*, *Nephrodium molle*, *Phegopteris trichodes*, *Polystichum coriacum*, *Pteris serrulata*, and its varieties, and similar plants, most of which can be provided by sowing spores, and keeping them in the seedling box for the occasion.

*Hemanthus* are nearly all natives of the Cape of Good Hope, and if allowed to flower at their natural season may be treated as greenhouse or conservatory plants. After growth is completed and the leaves have decayed, the pots should be laid on their sides in some dry and cool place. I am not, however, an advocate for too severe a system of resting. Those kinds which come from tropical Africa must receive the temperature of the stove, and must not be so thoroughly dried off as the Cape kinds. The soil should be good sandy loam, to which may be added a little peat and leaf-mould, and when the scapes begin to push an occasional application of weak liquid manure will be highly beneficial. The genus comprises a vast quantity of species, some of which are not conspicuous for their beauty, and which would only be tolerated in botanical collections, where they should be grown for the instruction of the many. The following kinds, briefly described, all deserve attention from those who love a variety of flowers rather than masses of two or three kinds only. I may add that a plant of *H. coccineus*, or many others, with, say, six or seven umbels of brilliant flowers, surrounded with small and elegant Fern fronds, is no mean object in a vase in the drawing-room; and in such a situation they survive a considerable time, and the plant itself is sure to take no harm.

**H. puniceus.**—Leaves oblong, waved at the margins, and pale green; the flowers are erect, produced in large umbels, and are pale red; the scape and involucre are green, both being streaked and spotted with blood-red. It blooms naturally in April and May, and with a little forcing may be had in flower before the snow has disappeared.

**H. quadrivalvis.**—This is a very beautiful species; leaves usually in pairs, lanceolate and acute, less than a foot in length, and dark green, furnished at the margins and on the whole upper surface with long hairs. The scape is erect, green, and dotted with crimson, and supporting a large four-lobed brilliant scarlet involucre. The flowers are also scarlet, whilst the stamens are bright yellow. It blooms in September and October, and no more beautiful plant could be desired at that season.

**H. rotundifolius.**—A fine plant, producing its leaves in pairs, one of which is, however, invariably larger than the others. They are some 5 inches long and 4 inches broad; dark green on the upper side, and have a rosy pink margin of hairs. The scape and involucre are both of a rich deep crimson colour; the tube of the corolla white, and the remaining portion red, with large golden yellow stamens. It flowers in July and August.

**H. tigrinus.**—This is a noble species, and one which I have found extremely useful for early forcing. The leaves are large, depressed, dark green, and slightly spotted with a marginal fringe of hairs. The scape supports a large-spreading, fiery-red involucre and umbel of red flowers, whilst the stamens are bright yellow. It blossoms naturally in April.

**H. pubescens.**—Although not so ornamental as some species, this is a great favourite of mine for the sake of agreeable contrast. Three or four leaves are produced together, somewhat tongue-shaped, dark green in colour, prettily fringed with white hairs. The scape is green, furnished with numerous soft hairs; involucre yellowish green, streaked with a dark shade of the same colour; flowers erect, white, with the numerous large anthers brownish yellow. It flowers in June and July. Known also by the name of *H. albilos*.

**H. natalensis.**—This beautiful species is of somewhat recent introduction. The leaves are large, of a dark green colour, and have their base clothed with beautifully-coloured sheaths. The scape is erect, and bears a large, even involucre, which is of a rich crimson purple colour; the umbel of flowers is pale green, and the anthers of a bright orange colour. Its charming flowers are displayed in the dreary month of February.

**H. coccineus.**—This grand species is, as far as I know, the finest of all the South African kinds. The leaves are somewhat tongue-shaped, and dull green in colour. The scape is erect, green, spotted and dotted with black and dull crimson; the involucre is very large and spreading, and consists of many bracts, which are deep red, veined with crimson. The large umbel of flowers is dull red, and the large anthers are of a bright yellow colour. These superb flowers are produced in September and October.

**H. multiflorus.**—This is an extremely showy plant, differing

from the previously named kinds in having a small and inconspicuous involucre. The leaves are oblong lanceolate, clasping at the base, smooth, and pale green. The large, many-flowered umbel is spreading, flowers deep blood red, whilst the stamens are purple and yellow, and much exerted. It blooms in July, and is a native of Sierra Leone.

**H. cinnabarinus.**—This, like the last-named species, produces flowers and leaves together—and, indeed, they closely resemble each other. In the present species the leaves are large, sheathing at the base, and the bulb is produced into a long neck. The bracts of the involucre are small and inconspicuous; the umbel of flowers large and spreading, with the stamens much exerted, and wholly of rich

## CROTON HOOKERI.

Among Crotons may be found some of the most beautiful of plants, remarkable alike for their stately habit and for the highly diversified and brilliant variegation of their leaves; some of these are long and narrow, as in the case of *C. Johannis* and *longifolium*; others are irregular in shape, as in *C. irregulare*, *interruptum*, and *multicolor*; others again are beautifully undulated or waved on the edges, like *C. undulatum*; horned, as in the case of *C. cornutum*, the midrib of which terminates in an upright horn-like process, half an inch or so

Croton Hookeri.

cinnabar red colour; the anthers are yellow. It is a native of Western Africa, and blooms in August.

There are many more species than I have here enumerated. Many of them, I am told, are exceedingly beautiful; but, not having seen them, I have confined myself to those kinds which have passed through my hands and can be confidently recommended. The two last-named kinds are stove plants, or at least require a greater heat during the winter months than the others, which are all natives of the Cape of Good Hope or South Africa, and consequently thrive under ordinary greenhouse treatment; but even these are benefited by a little heat when growing late in the season.

G. FIELD.

from the extreme end of the leaf; and others are spiral-leaved, like *C. spiralis*, a beautiful new variety. Another section of this genus has compact, oval foliage, such as *C. pictum*, *variegatum*, and *aucubaefolium*. The colour and marking of the leaves are also as variable as their shape; in *C. multicolor* there is, as its name implies, a combination almost, indeed, a confusion of hues, consisting of green, yellow, red, and crimson; *C. aucubaefolium* is spotted with yellow, like the *Aucuba*; *C. pictum* has a crimson ground colour, richly spotted with yellow and black; *C. undulatum* is deep metallic green spotted

with yellow and vivid crimson, and *C. Veitchii* has a broad band of yellow along the centre.

*C. Hookeri*, the subject of the accompanying illustration, is one of the finest of the genus. It is a compact yet free grower, and a native of the South Sea Islands, whence it was introduced into this country by the late Mr. J. Gould Veitch. Its leaves are broadly ovate-lanceolate and abruptly tapering or rounded at the base. The petioles are an inch or an inch and a quarter long, and the leaf-blade from 7 to 9 inches long by  $2\frac{1}{2}$  to 3 inches broad. The midrib, young stems, and leaf-stalks are of a bright golden colour, a broad band of which traverses the centre of the leaves, irregularly projecting on both sides of the midrib. The upper surface ground colour of the foliage is a beautiful dark shining green, and the underside considerably paler. Like others of the genus, it requires a stove temperature. A compost of three parts good substantial loam and one of peat, with a little sharp silver sand, suits it admirably. During its period of growth it requires a strong heat and abundance of root and atmospheric moisture. In winter a temperature between  $55^{\circ}$  and  $65^{\circ}$ , with the usual daily rise with sun-heat, will suit it perfectly. Water in moderate quantities must also be applied, for, like all other coriaceous evergreen-leaved plants, it will not suffer drought with impunity. A position near the glass is necessary, in order to enhance its brilliant leaf markings. The young wood and foliage are usually pale in colour, but they assume the true tints characteristic of the species after the wood has thoroughly ripened, and before the growth of the young wood of the succeeding spring appears.

When well nursed, plants of this species grow vigorously, and as soon as the desired dimensions are attained, they should be kept pot bound, so as to dwarf their future growth. They require abundance of water when root-bound, and the advantage of having so loamy a soil in preference to a peaty one consists in its being productive of firmer wood, more likely to stand uninjured the adverse circumstances to which plants are subjected when used for window or parlour gardening. Some cultivators grow them for two and sometimes three years without shifting them, but this treatment soon induces an impaired constitution. It is a good plan to have an old plant from which a few cuttings can be taken annually in spring or in August; insert them in small pots of peaty sand, surfaced with pure sand and cover them over with a bell-glass. The pots should be plunged in bottom heat and closely shaded for a time. When well rooted shift them into better soil and sixty-sized pots, and still give a brisk root temperature, and keep them growing as vigorously and healthily as circumstances will permit. In this way a succession of fine young plants, suitable for any purpose, is always at command, which, when they have become too large, can be thrown away. The finer kinds may also be grafted on the strong growing sorts. Side and cleft grafting are most suitable, and they can be performed either in spring or autumn, the pots being plunged and shaded like those containing cuttings.

WM. FALCONER.

#### NOTES AND QUESTIONS ON THE INDOOR GARDEN.

**Rhododendron Princess Royal.**—I find this to be one of the most useful of all pot plants, especially at this time of the year. I have a plant of it that has been in bloom now for more than eight weeks. It is in a large sized pot, and it has borne eight trusses of bloom. All that it requires is the protection of a greenhouse in winter.—T. R. H., *Kenwood*.

**Dendrobium nobile.**—Of this I have a charming plant now in full bloom, and associated as it is with a few Ferns, Lily of the Valley, and Tea-scented Roses, it makes the early vinery in which it is growing nearly as gay as a conservatory. We may have had Dendrobies more handsome; but in point of usefulness none surpasses *D. nobile*, and it is so easily managed that everybody who has a warm greenhouse may grow it.—R. GILBERT, *Barghley*.

**Panicum variegatum.**—I have a nice plant of what is usually called *Panicum variegatum* in our early vinery, finely in flower. It is associated with small plants of *Coleus* and Ferns, which, under a canopy of green Vine leaves, have a pleasing appearance at this season of the year, and make the house a favourite resort for all lovers of fine-foliaged plants.—J. GILBERT.

**Sparmannia africana.**—This is a useful old white-flowered plant, cuttings of which may be inserted at any season, and soon make nice little blooming plants. Even if this plant were less interesting than it is in a decorative or floral point of view, it would still be worth culture as a souvenir of Captain Cook's second voyage round the world. It is also remarkable on account of its being furnished with irritable stamens, which expand slowly if touched, more especially during bright sunshine. This action differs from that of the stamens of *Berberis*, which contract closely round the style, while these expand or recede from it.—F. W. B.

#### TREES.

Father, thy hand  
Hath rear'd these venerable columns, thou  
Didst weave this verdant roof. Thou didst look down  
Upon the naked earth, and forthwith rose  
All these fair ranks of trees. They, in thy sun  
Budded, and shook their green leaves in thy breeze,  
And shot towards Heaven. The century-living crow,  
Whose birth was in their tops, grew old and died  
Among their branches, till, at last, they stood,  
As now they stand, massy, and tall, and dark,  
Fit shrine for humble worshipping to hold  
Communion with his Maker. These dim vaults,  
These winding aisles, of human pomp or pride  
Report not. No fantastic carvings show  
The boast of our vain race to change the form  
Of thy fair works. But thou art here—thou fill'st  
The solitude. Thou art in the soft winds  
That run along the summit of these trees  
In music; thou art in the cooler breath,  
That from the inmost darkness of the place,  
Comes, scarcely felt—the barks trunks, the ground,  
The fresh moist ground, are all instinct with thee.  
Here is continual worship; nature, here,  
In the tranquillity that thou dost love,  
Enjoys thy presence. Noiselessly, around,  
From perch to perch, the solitary bird  
Passes; and you clear spring, that, 'midst its herbs,  
Wells softly forth, and visits the strong roots  
Of half the mighty forest, tells no tale  
Of all the good it does. Thou hast not left  
Thyself without a witness, in these shades,  
Of thy perfections. Grandeur, strength, and grace  
Are here to speak of thee. This mighty Oak—  
By whose immovable stem I stand and seem  
Almost annihilated—not a prince,  
In all that proud old world beyond the deep,  
E'er wore his crown as loftily as he  
Wears the green coronal of leaves with which  
Thy hand has graced him. Nestled at his root  
Is beauty, such as blooms not in the glare  
Of the broad sun. That delicate forest flower,  
With scented breath, and look so like a smile,  
Seems, as it issues from the shapeless mould,  
An emanation of the indwelling Life,  
A visible token of the upholding Love,  
That are the soul of this wide universe.

W. C. BRYANT.

**Bamboo Poisoning.**—A singular peculiarity belonging to the Bamboo has been communicated to us by M. Lafou, whose attention we were directing to the fine prickles with which the stem of the *Bambusa Thunarsii* is covered. "I had," said he, "in my employ a Chinese who, on seeing me cultivate this Bamboo, assured me that his countrymen used these hair-like prickles when they wished to kill an enemy, without the risk of being discovered. They gather these small needle-like protuberances, and place them surreptitiously on handkerchiefs, beds, or in any place in which they are likely to touch the nose of their enemy; they thus introduce them into the nostrils, where they irritate the membrane, causing a severe cold in the head. This becomes more and more serious; then follows inflammation, then an active suppuration, with intense pain, and thus the victim gradually dies a fearfully painful death, without its being possible to save him. This is unfortunately constantly used, and we have been also assured of the truth of it by Dr. Savatier, a naval medical man, who has lived in China, and is now in Japan.—ED. ANDRÉ, *Illustration Horticole*.

**The Discovery of Coffee.**—According to vulgar tradition, the discovery of coffee is due to the mollah Chadelly, whose memory is held in reverence by all true Mussulmans. The pious man, afflicted with sorrow at the thought that he could not keep awake for the performance of his nocturnal devotions, besought Mahomet to indicate some means by which sleep might be chased away. Mahomet, touched with pity, as well he might, seeing that his own honour was concerned, so brought matters about that a herdsman came to acquaint mollah Chadelly of the curious fact that his (the herdsman's) goats could not go to sleep after they had partaken of coffee berries, but kept frisking about all night long. The mollah, taking the hint, at once prepared a good strong dose of coffee. He drank it, and was delighted beyond measure at the result. Not a wink of sleep did he get; delicious sensations crowded on his brain; and his midnight devotions were so fervent that he at once communicated the precious secret to some dervises, who, imitating his example, beleaguered the prophet, now in the seventh heaven of bliss, with unceasing prayer.

## THE INDIAN THORNY OR SPREADING ACACIA.

THE accompanying sketch represents an Acacia that is found in all hot dry districts, from Arabia to the extreme limits of Southern India; and it differs so slightly in its characteristics from the *Acacia nilotica*, found in Egypt, that I am inclined to think the two are identical. Spreading much in the same manner that our Thorns do in England, and attaining a considerably greater size, these Acacias form most picturesque objects on torrid landscapes, and when covered with millions of small golden globular flowerets, and full of Mimosa-like foliage, they are at once striking and effective. To the inhabitants of the parched countries in which this Acacia is found, it is truly a great boon, growing luxuriantly where other trees can scarcely exist. It helps to form a portion of the scant supplies of fuel required by the Arabs and Indians to cook their food, and along with the Date Palm forms almost the only shade and tree verdure to be found in countries in which it grows.

To the natives of districts through which the navigable rivers from the great central water-sheds flow, it has a tenfold value; its durable curved limbs, grown naturally to the shape of the ribs of a barge, serve to form, with little labour, the

A Spreading Acacia.

framework of the rude, heavy boats, by means of which the river commerce of those countries is carried on. From the Delta to the cataracts of the Nile, in the vicinity of every Arab village, this Acacia is cultivated on the waste lands of the mounds on which the villages are built. Like all the Acacia family it produces seeds freely, from which it is propagated, and, when once established, its vitality is such that it will flourish even in dust and blowing sand, the roots striking deeply into the earth in search of moisture. This Acacia also furnishes a gum, which is valued by the natives for the purpose of dentistry, and from the bark is manufactured a bright yellow dye for cloth and leather. PETER WALLACE.

**Plant Sales.**—In spite of the old motto, *Caveat emptor*, we think it would be desirable in all plant sales that the plants, bulbs, seeds, &c., should be correctly named, or if this be not practicable, or if a doubt exists, then that this should be openly expressed, so that the purchaser may not be misled. Wherever it could be done it would also be an advantage to have the consignee publicly stated, as that alone would be a pledge of good faith; but we can quite understand that there are certain cases where this cannot with propriety be done. At any rate we believe it would be to the interest of all parties if some reforms were introduced into sale catalogues and sale rooms.—*Gardeners' Chronicle*.

## RECOLLECTIONS OF JOHN CLAUDIUS LOUDON.

BY NOEL HUMPHREYS.

(Continued from p. 531, Vol. II.)

It will have been seen that Loudon had thrown all his energy and various knowledge into the thorough reformation and replantation of the model farm at Tew; and that to the buildings also he had devoted an equal amount of attention. The cost of these was, however, defrayed by General Stratton, who had given his energetic tenant *carte blanche* as to the extent and character of the structures he might deem requisite. Even the kind of horses for the farm work was most carefully considered; and the Cleveland breed preferred to all others. In short, the principal farm, and all the smaller farms included in the lease, were improved so rapidly that the whole might have been relet at a largely increased rental within two years of Mr. Loudon's taking possession.

The success of the principles and working system thus applied, induced the young farmer to publish an elaborate account of the works he had carried out at Tew, as a successful example of the northern system. He had thrown all his best energies into those improvements, and never lost sight of his great principle that "tillage should beautify the land"

and not disfigure it; in short, that the farmer should be at the same time a landscape gardener; because, labour being the highest of all human vocations, it ought to be invested with beauty.

At the beginning of the handsome work describing the improvements at Tew and other places, there are two capital panoramic views of the place; one looking from the house towards the fields, and the other from the fields looking towards the house. The engravings, which are exceedingly well executed, convey an excellent idea of the planting of the entire property, on which the author looked forward at one time to spending his entire life; but this was only a passing determination, and soon gave place to more restless views. The other places described in his work on the improvements at Tew, which was published in 1811, were, I believe, his original plans for improving Lord Mansfield's estate at Scone, and some other examples of his system, carried into effect in England.

One of the many schemes he set on foot during the brief but active period of his residence at Tew, was the establishment of a kind of agricultural college for the suitable education of farm bailiffs and others engaged in agricultural pursuits. He gave some account of this college in a pamphlet entitled, "The Utility of Agricultural Knowledge to the Sons of Landed Proprietors, &c., with an Account of an Institution

formed for Agricultural Pupils in Oxfordshire, &c." It is in his introduction to this work that he alludes to his determination to have recourse to farming as a permanent source of income, lest by any future attack of disease he should be prevented from the more active duties of his profession as a landscape gardener.

His activity both of mind and body prevailed, however, over the drawbacks of the lameness and the disabled arm, and he continued, despite these difficulties, to follow his old profession; having between 1809 and 1812 laid out several places in England, in Wales, and even in Ireland. In the meantime he had given up the lease of Tew upon very advantageous terms, which were highly creditable both to landlord and tenant; and finding himself master of upwards of £15,000 as the result of his unceasing labours in various fields of honorable enterprise, he determined for awhile to take a period of rest from his usual avocations; but not with a view to inactivity. The waning fortunes of the first Napoleon, among the snows of Russia, towards the close of 1812, opened portions of the continent to English travellers, and in March 1813 Loudon determined at once to avail himself of this opportunity to gratify his long-cherished wish to see the countries of the continent, at all events such portions of them as he might then find it possible to traverse.

With his peculiarly liberal cast of mind, Loudon had long fretted against the narrow sphere of observation and study within which he was confined in the limited extent of the British Isles; especially at a time when national vanity, combined with obstinate insular prejudices, so cramped the range of English thought in general, that anything like a fair judgment of continental arts, sciences, taste, institutions, and manners could not be arrived at in England by men of routine education, holding the narrow stereotyped opinions so generated. It was under the influence of such a phase of national thought that England had joined, heart and hand, in a kind of crusade against the right of the French people to choose their own form of government—a crusade which Loudon regarded as a more benighted and in every way darker and more ignorant proceeding than the sanguinary expeditions to the Holy Land of the middle ages. He looked forward with great glee, as I have heard him say, to this opportunity of casting off the confining coil of insular thought, and finding out for himself sufficient reasons for adopting wider and more cosmopolitan opinions than those he had found prevalent among all classes in England, and indeed in Scotland also, as he freely confessed.

With such feelings and aspirations he started from Harwich on the 16th of March, 1813, in a small sailing packet, the discomforts of which were considerable; but he had no choice, for steamers were at that time not even a vision of the future in their present comfortable form, though a few tentative experiments had been already made by enterprising men, who were deemed little better than poor infatuated lunatics by their hard-headed contemporaries. He arrived at Gottenburg, in Sweden, after a tolerably fair passage, in so far as weather was concerned; and was much struck by the novelty of the scene which presented itself, and which at that time wore so many quaint national peculiarities which modern facilities of intercommunication have since so much toned down, that a traveller must go very far afield to meet with sights and scenes as strikingly novel as those which in 1813 unfolded themselves to Loudon on his landing in Sweden. He was much struck with the advanced state of two great elements of civilization in that country—road making and education; in both of which he considered that little monarchy far in advance of England, especially in the last named—education; inability to write, even in the lowest grades of the social scale, being the exception instead of the rule, as it then was in England, which, as Loudon always regretted, was far behind Scotland in that respect, and indeed still is so, the registrar-general's recent returns of marriages exhibiting *marks* instead of signatures to the amount of nearly one-half on the *ladies'* side, and one-third on that of the *gentlemen*. Many things in Sweden reminded our traveller of Scotland, and he felt convinced that the Norse element was even stronger in the northern portions of the highlands than had ever been suspected. He often expressed regret that he did not remain

longer in Sweden, in order to study the national institutions and the manners of the people more thoroughly; and still more specially the magnificent scenery, from which he had expected to derive many hints for the enlargement of his theories of picturesque landscape gardening; but he became so overpoweringly anxious to visit the scenes of the great European war that was then rapidly culminating in the overthrow of the first Napoleon and his hosts, after the disastrous invasion of Russia, that he could not resist the temptation of pushing forward at once, leaving undone much that he had intended to accomplish during a short stay in Sweden.

Incited by this irresistible desire to witness some of the last aspects of the gigantic war-struggle, he pushed on to Königsberg at once, by way of Memel, and arrived there on the 14th of April. On nearing that place he began, as he relates in his journal, to find everywhere the devastating traces of war, all of them more or less terrible to the eye of one coming from a country which for ages had not known the horrors of invasion. Skeletons of horses, whose flesh had been devoured by wolves, still common in the Baltic provinces, lay bleaching where they had fallen, the victims of famine or battle. The roads were broken up; cultivated fields trodden into wastes; and gardens and country houses which he would have so much delighted to see in their trim and well kept completeness, as models to study, he found but too often reduced to shapeless wrecks. So that as a horticulturist and landscape gardener he found but few things to study professionally; but the passages in his journal relating to the time show how deeply, as a philanthropist, he was interested in the great European crisis.

At Ebling, a small fortified town, he was much struck by the scenes in the narrow streets, which were, he says, completely jammed with the goods and cattle of the people of the surrounding country, who had poured into the town for protection from the foraging parties of a part of the French army which was then passing within a few miles; devouring or spoiling, in self-defence, all that came in their way. Near Marienburg he passed through a bivouac of Russian troops, who had by no means the soldierlike air that he had expected in men who had so successfully repulsed the great French armies, and which had been spoken of as such splendid soldiers by English newspaper writers. Near Danzig he was much interested in a new kind of architecture, by which, as he described it, "houses were made by sinking down, instead of raising up." This process was very skilfully performed by a horde of Cossacks belonging to the Russian camp on the hills near Danzig. It was effected by making excavations in the deep, loose sand, of which those drift-hills are chiefly formed, the approach being by a well managed declivity, and the roof being formed of branches of trees raised above the excavation in the form of a tent.

On approaching Berlin, he found the long avenues bordered with trees, through which the city is reached, thronged with a continuous train of foot and carriage passengers, and waggons piled with luggage, hastening to the city for protection; and as his view of this busy and exciting scene was taking place by moonlight, Loudon, whose eye had long been cultured to a full appreciation of the picturesque, was very much struck with what he saw; and gave a detailed and very graphic account of it in his journal, which he never neglected, but which, from the large admixture of strictly private matters, was not calculated for publication. He remained in Berlin from the 14th of May to the 1st of June; receiving anything but a favourable impression of the Prussian capital. The dirtiness of the streets, the comfortless character of the houses, the fearful stench consequent upon bad drainage, or rather no drainage at all, and the utter absence of any public buildings worthy of notice, excepting perhaps the arsenal,\* made him really anxious to quit a disagreeable place, that had nothing metropolitan about it except its size and its dirt; the splendid side of other metropolitan cities being entirely absent in Berlin. He therefore pushed on to Frankfort on the Oder, where he was well received by a party of German officers who had never seen an Englishman, and with whom this country was then extremely popular, on account of the lavish

\* The museum, town hall, and other buildings of some beauty, are of recent erection.

subsidies of British money, by means of which they had been enabled to carry on their share of the great European crusade against France. From thence he proceeded through Posen to Warsaw, where he saw many things that greatly interested him, especially many ancient buildings in a curious transition style of architecture which is only to be met with in Poland; and which he was enabled to study very carefully, perhaps more so than he really desired, as he was detained for three entire months, on account of a trifling informality in his passport, at the little town of Tykoczyn, from which, however, he was allowed to make excursions into the surrounding country, of course under armed escort.

(To be continued.)

## THE FLOWER GARDEN.

### CORTUSA MATTHIOLI.

This handsome plant is closely allied to the Primulas. It very much resembles *Primula cortusoides*, and has large leaves like those of *P. mollis*. The flowers, which appear in early summer, are of a deep purplish-crimson, and are produced in loose drooping umbels on stems from 9 to 15 inches high. The corolla is funnel-shaped, with pointed divisions. It should be

*Cortusa Matthioli* (after Vilmorin.)

grown in sheltered nooks in the rock garden, or on sheltered borders, in moist loam or peat, mixed with about a fourth part of pounded slate. It may be multiplied either by division in spring or from seed, which should be sown as soon as it is gathered, and placed in a shady position. The seedlings should be wintered under a frame and will flower the ensuing year.

### BULB NOMENCLATURE.

MR. EDITOR.—I have had such a horrible dream! Possibly you may not know, but I speculate in a few bulbs—say half-a-crown's worth—every autumn, and I don't always purchase from the same merchant, but sometimes from one and sometimes from another, as it suits my fancy. The consequence is, that they have all got me in that dreadful book which they call their "Register," and catalogues and sundry other documents pour upon my devoted head every season, "thick as the leaves in Vallambrosa." The "Autumn Guides for 1872" that I have received since the beginning of September are, like their contents, "too numerous to mention." Some of the firms are not content with sending me their catalogues, but, if I do not send them an order in a few days, I receive such a touching epistle as the following:—

"My dear Sir!—Not having received this season your customary order for bulbs—"

Why, four years ago, I sent to this firm for one shilling's worth of Croci (*Crocus* is right, I have South Kensington authority for it), and I never had anything else before or since. Well!

"Not having received your order, we take the liberty of reminding you of the same, lest it may have escaped your attention. Perhaps you are not a buyer of bulbs this season. Perhaps you were not satisfied with the goods supplied on a former occasion. Perhaps you have given up gardening pursuits. Perhaps you will not be at home at the blooming

season. Perhaps family afflictions have caused you to retire from such occupations for a time. Perhaps you are deceased, in which case kindly let us know by return, and we shall take your name off our 'Register!'" In fact, they suggest no end of peradventures.

The other night, after some serious consideration as to the propriety of bolting off during the bulb season to the Norway fisheries, or any other *terra* where catalogues are *incognita*, I went to bed and fell into a troubled sleep—

And as I slept, I dreamed a dream.

And, lo! I stood upon an immense plain—

a sort of Bog of Allen, and instinctively understood that I was in the Spirit Land of the Bulbs; for all around me I could perceive the shadowy forms that represented the various sections, groups, and divisions of those awful catalogues, compounded into genera, species, and sub-species, varieties, sports, and many other distinctions, which, if they wouldn't, ought to puzzle a Dutchman. And before me arose a figure, as it were, of a Priest of the Bulbs, who brandished a fat catalogue. Wiping his spectacles, this presiding genius emitted a huge preliminary "Hem!" and accosted me—

"Sir! There hath been great confusion in the nomenclature of everybody and everything. Clusius, Haworth, Herbert, and Parkinson"—

But here a great rushing noise interrupted him, and he was immediately swept out of sight, as the Spirits of the Hyacinths whirled round me in a rapid waltz. By all that is wonderful, what a motley throng! Here was Baron Rothschild embracing the Sultan's Favourite, Howard doing the amiable to Adeline Patti, Uncle Tom pirouetting with Anna Bolena, Voltaire embracing Dolly Varden, the Duke of Wellington whirling past in the arms of Netherlands Glory, Cavaignac embracing with the Beauty of Waltham, Linnaeus with the Princess Royal, Victor Emmanuel with Mrs. Beecher Stowe, Telemachus with Queen Victoria, Prince Albert with Madame Van der Hoop, Sir Edward Landseer with Cleopatra, and Charles Dickens with Lady Havlock.

Dante in *Inferno* never saw such a combination. Of a verity the Bulb Priest was right. "There hath been great confusion in the nomenclature." So I turned mine eyes aside in my dream, and beheld advancing a sweet procession of those darling spring flowers, the Narcissi, or as they were called in the good old times, when a spade was a *spade*, and not a *Pala longa manibus patibuscque*—the dear Daff-a-down-dillies. But they seemed sad and unhappy, and approached me with tears and lamentations.

"Look at me!" sighed a blooming beauty whom I had known from my childhood. "They call me now Pseudo-Narcissus aureus maximus flore pleno sive roseus Tradescanti, and have doubled my price accordingly."

"Who will know me!" cried another, "as a Corbularia."

"Mercy on me!" said old double Daff, "who'd a' thought I were *Telamonius plenus!*"

"Bother it all!" growled our ancient friend, Butter and Eggs. "They have been and nicknamed me *Incomparabilis albus plenus aurantiacus!*" While, one more unfortunate, a sweet little creature, sighed as if her little heart would break and murmured, "What have I done to be called *Tros poculiformis!*"

"Verily, verily," said I, as I shut my eyes upon the melancholy group—"There hath been *very* great confusion in the nomenclature."

When I looked up again, lo! my old favourites the Tulips were going, going to the highest bidders. A Rhinoceros went for 2½d., and a Keizerskroon for 3d.; the Comte de Mirabeau only fetched 2d., the Prince de Galitzin went for the same money. Queen Victoria was knocked down for 1d., General Garibaldi went at 2½d., Maria de Medicis at ¾d., the Duke of York at 1½d., Molière at 3d. I am sorry to say that the Markgraaf van Baden was sold for 1½d., the Bride of Haarlem in pure white could only command 6d., and Cottage Maids were bought up with facility at half-a-crown a dozen.

"Of a truth," repeated I, turning away with a sigh—"There hath been *particularly* great confusion in the nomenclature."

But I was suddenly aroused by a great uproar, and looking

round, beheld the plain covered with Lilies, who, despite their lovely aspect, were in violent contest. They had been ordered to classify themselves and they wouldn't. So they had quarrelled over it, and at it they went trumpet and perianth.

"You're an Eulirion!" shouted one.

"You're an Isolirion!" bawled another.

"I'm the original Lancifolium!" said a third.

"You're nothing of the sort!" retorted his neighbour.

"You're only an antiquated Speciosum!"

"Make way for Aurantiacum croceum!" was the cry of another.

Upon this, the Turks' Caps commenced an awful row, old Purple declaring that he was the only Martagon, and that the rest were impostors; and the others, joining in the fray, there was presently an indescribable hubbub, in which all order was lost in the Babel of Sounds.

Far above the turmoil I heard again the voice of the Bull Priest shouting, "There hath been great confusion in the nomenclature"—and so I awoke, murmuring to myself, "By the depths of the Zuyder See, there hath, indeed, been great confusion in that direction."

D. G.

Eden Lodge.

### A VEGETABLE MARVEL.

On the eastern spurs of the Rocky Mountains there grows an alpine plant of extraordinary beauty. In habit it resembles our common Wild Thrift, or Sea Pink; but its rosettes of leaves are much larger (1 or 5 inches across). From the base of these, and scarcely an inch above the ground, a profusion of blossoms arise; each flower being three inches or more across, and of the loveliest shaded pink and rose colour imaginable. The whole reminds one of a large Mesembryanthemum, with ten or twelve very broad petals, forming compact, circular flowers. The thick, woody rootstock of this curious perennial descends to some depth among the fissures of rocks, or stony, well-drained soil which it inhabits. Its tenacity of life is something wonderful. After being immersed in boiling water, and afterwards pressed as a specimen for the herbarium for more than eighteen months, a plant has been known to grow and flower. Its root is eaten by some of the Indian tribes, who esteem it very highly. The plant is *Lewisia rediviva*, an ally of the *Portulacas* and *Calendrinias*. We have had it two seasons, but received our main supply last year. It grows and flowers freely, and is perfectly hardy.

York.

JAS. BACKHOUSE.

[A figure of this singularly beautiful plant will be found at p. 701 of the first volume of THE GARDEN.]

### PLANTS IN BLOOM ON NEW YEAR'S DAY.

In addition to the plants enumerated as being in flower at Mr. Ellacombe's on Christmas-day, the following were in bloom here on January 1st, viz.:—*Laurustinus*, *Pyrus japonica*, *Erica carnea* and *Seerlei*, *Tritoma Uvaria*, East Lothian Stocks (three colours), *Helleborus foetidus*, *Violas* (Dickson & Co.'s varieties), Russian Violet, *Colchicum* (double striped lilac and white, the leaves of the single varieties are 1½ inch above the ground), *Crocus odoratus* var. *longiflorus*, five varieties of single *Primroses*, nine sorts of *Polyanthus*, two sorts of *Oxlip*, one *Cowslip*, *Primula nivalis*, *Carnation* (rose self), *Dianthus multiflorus* (white and rose) *Aster ericoides*, *Hepatica* (single blue, white, red, and double red), common pink and scarlet China Roses, *Daisies*. The list would have been considerably longer had we not resolved to have every corner of the garden in first-rate order by the last day of the year—a resolution which the weather enabled us to carry out; and owing to circumstances the gardener, in his extreme activity, cut over the herbaceous borders, an operation I always prefer to do with discretion myself. Snowflakes and a Snowdrop were out in the first week of January. The bare places on the banks were beautifully green with *Cherophyllum*; in fact this plant has never rested this season. In a neighbouring garden I observed *Ecermocarpos scaber* in flower.

F. J. HOPE.

Wardie Lodge, Edinburgh.

**Plants in Flower in Sussex.**—The following are now in bloom in the garden at Hawksfold, which is sheltered to the north and east by high hills, and open to the south and west. It is about 300 feet above the sea level. Of scarlet *Rhododendrons*, several kinds are in full flower, as are also *Snowdrops*, *Crocuses*, *Primroses*, Christmas Roses, *Laurustinus*, Czar Violets, Prince of Wales and Gloire de Dijon Roses, white and purple garden *Anemones*, *Daphne Mezereum*, Wall-flowers, Stocks, Sweet Rockets, yellow *Alyssum*, *Andromeda*, *Erica*

*carnea* and a white *Heath*, *Arbutus*, *Furze*, *Myosotis dissitiflora*, *Escallonia rubra*, and *Iberis sempervirens*. A large Myrtle under the shelter of the house, but not trained, has many flower-buds on it, some partly expanded. A variegated *Camellia* in the same situation has also partly expanded its flower-buds. The following wild flowers are also in flower, viz., white *Periwinkle*, *Daisies*, *Buttercups*, and *Ragwort*.—S.

### NOTES AND QUESTIONS ON THE FLOWER GARDEN.

**The Winter Heliotrope.**—A large patch of *Tussilago* (*Petasites*) *fragrans* is now in full bloom in our garden, and quite perfumes the air as one passes along the walk which is near it. Anything that blooms at this "unseasonable" time of year is surely doubly valuable. I saw it far above the level at which perpetual snow lies on the slopes of "Sulu Tind"—the highest peak of that part of the central range of the Norwegian mountains, which is known as the "Fille Fjeld." We have lots of spring flowers in bloom, and a climate of almost summer-like mildness.—J. BACKHOUSE, York.

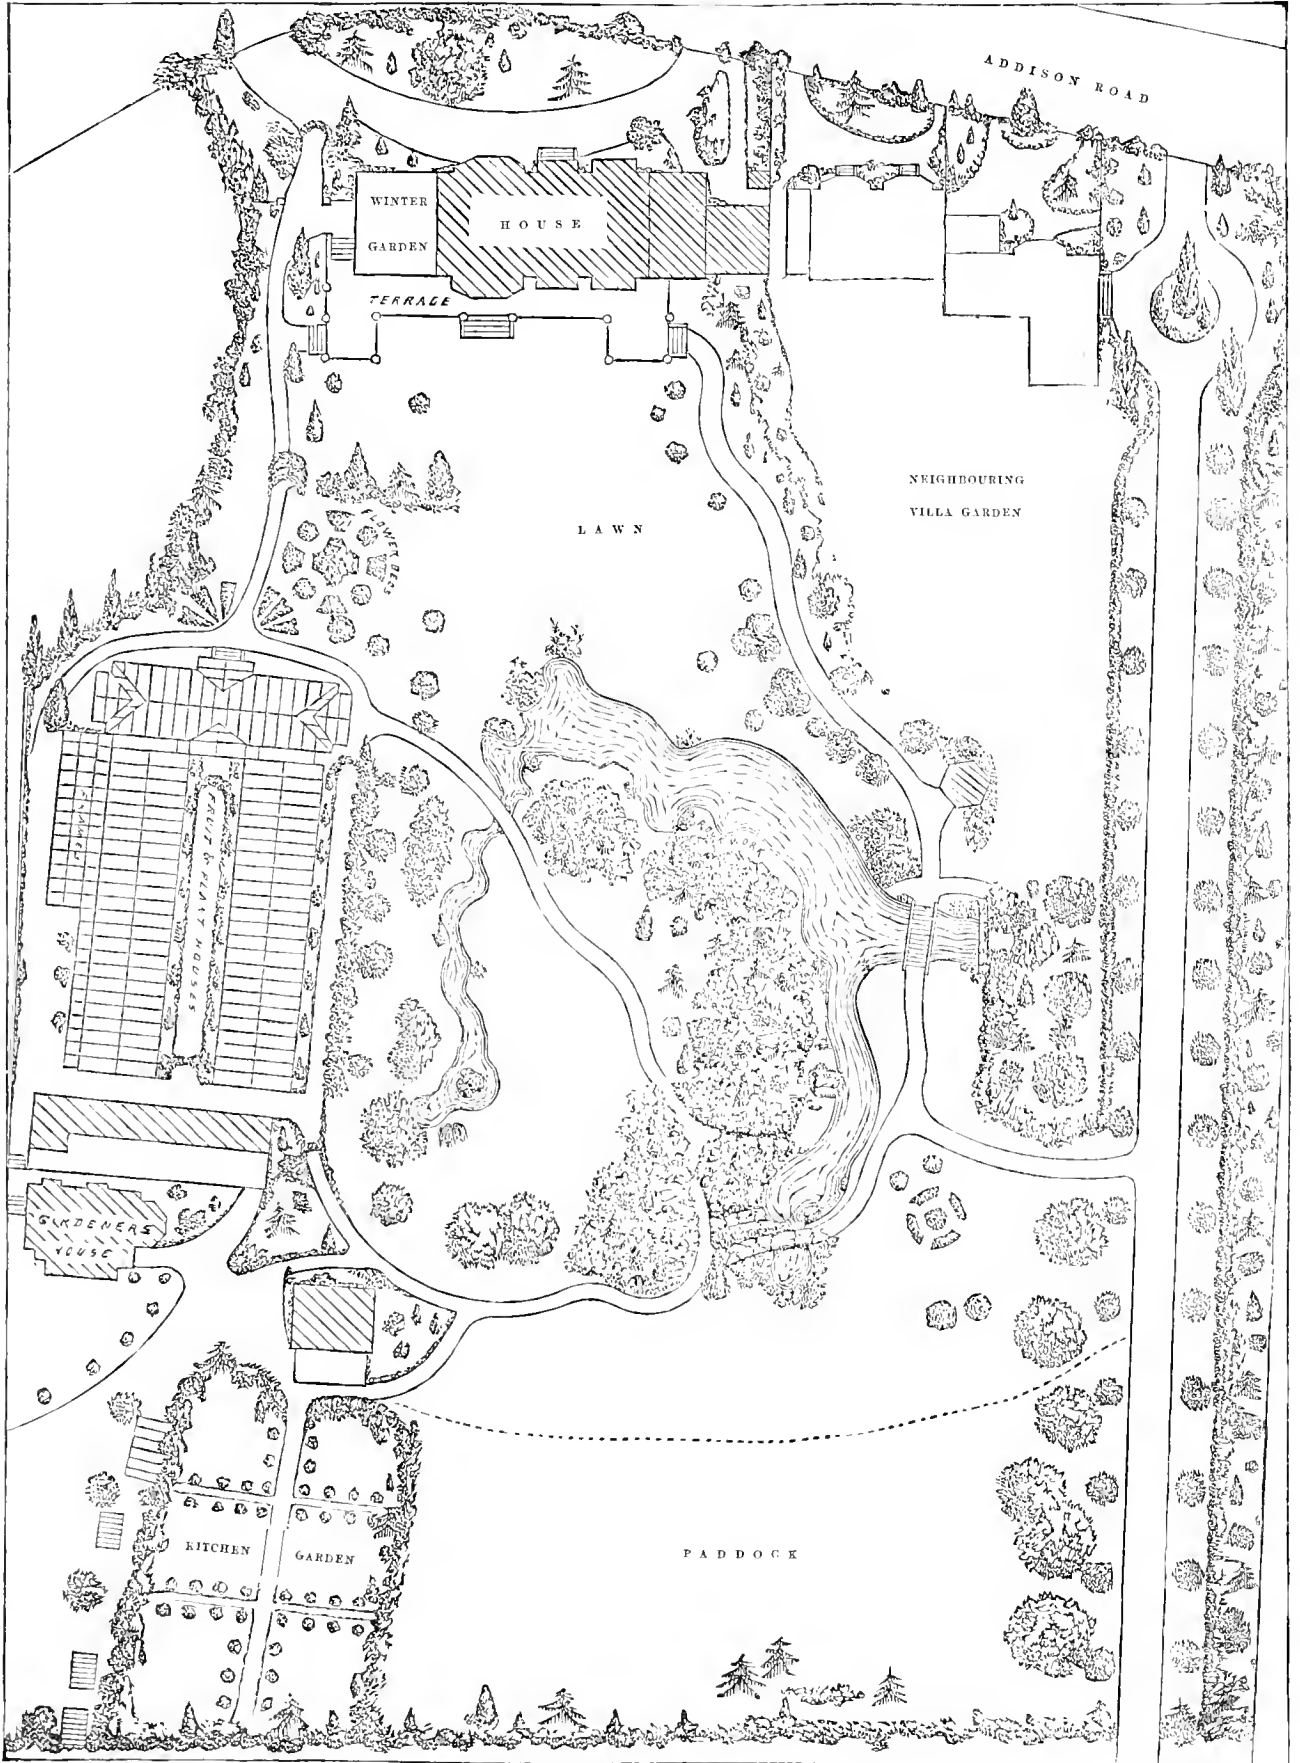

**Jasminum nudiflorum.**—Growing against the wall of one of a row of cottages that face the road leading from Feltham to Bedfont is a large neatly trained plant of this yellow-flowered winter Jasmine. This of course is no novelty, but what I desire to note is the spirit of imitation evoked amongst the other cottagers, all of whom have now a small plant trained on to the front of their habitations. As this Jasmine is easily propagated by means of layers, perhaps the more fortunate cottager kindly put his neighbour on an equality with himself. The large plant has been in flower for six weeks, and when I saw it on the 8th ult. it was as bright as ever.—A. D.

**Myosotis dissitiflora.**—Strong plants of this beautiful spring flower from seed sown the middle of July, and now growing on a south border, are already bursting their flower-buds, and with a continuance of the present mild weather will soon be a mass of celestial blue. This *Myosotis* should be propagated by means of seed, only, as the smallest seedling plants will stand both wet and frost much safer than the largest of old stools, and any reliance upon old plants, or on plants raised from side shoots, is almost certain to end in disappointment. Seed should be sown not later than July, and at all times in boxes or pans, so as to secure the seedlings against drought, on the one hand and slugs on the other. If some of the strongest plants are potted up into large sixties in October and put into a cold frame, they will assist in making both windows and greenhouses gay, from Christmas onward.—A.

## GARDEN DESIGN.

### PLAN OF THE GARDENS AT OAK LODGE, KENSINGTON.

We have often spoken of the beauty of the gardens at Oak Lodge, and of the striking landscape effects obtained there, in what may be termed a town-garden; we gave a page view of one of the most striking scenes in the gardens in Vol. I., p. 125, and now we issue a plan of the place, engraved from measurements taken on the spot. The plan, as will be seen, has many good points, though the effect of the ornamental water is, in reality, very much broader and better than it would seem to be, judging from the plan, which, of course, also fails to show the gentle and natural-looking undulation of the surface of the ground. The way in which the houses are grouped, so as to get a good many on a small space, and thus prevent them from encroaching too much on the space required for ornamental gardening, is excellent. A well-stocked conservatory-like structure is seen from the house, and behind it, in two parallel lines, run well-built ranges of plant and fruit houses. The flank of this group of houses that looks towards the garden is hidden by a high bank of shrubs and low trees. The space between the two lines of houses forms an excellent position in which to place greenhouse plants out of doors during the summer months. The kitchen garden, excellent gardener's house, &c., are also so placed as not to mar in any way the quiet beauty of the "home-landscape." Attached to the house is one of the most beautifully finished and well furnished little winter-gardens in England. The breadth of terrace is nicely proportioned to the position, and better than all there is quite an open little lawn, across which one gets the most charming views of the rock gardens, water, and richly-furnished shrubberies. The walks, it will be seen, are well concealed from the house, and are everywhere unobtrusive. The blank space represents the garden of an adjacent villa, beyond which an avenue leads through the grounds of Oak Lodge from the Addison Road to Holland Park, which is adjacent. The design of the garden is the work of Mr. Robert Marnock, and the place is always in the best condition under the management of Mr. Wilkie. We cannot conclude without acknowledging the happy and tasteful manner in which the really picturesque rockwork here has been executed by Mr. Palham, of Broxbourne; its effect from every point of view is of the happiest kind.

PLAN OF THE GARDENS AT OAK LODGE, KENSINGTON.

## THE GARDEN IN THE HOUSE.

## CULTURE OF PLANTS IN ROOMS.

(Continued from p. 557, Vol. II.)

## PLANTS USED FOR FORCING.

**Prunus Cerasus fl. pl.**—This is a particularly good subject for forcing. It is propagated by budding or grafting on *Prunus Malahab* or *P. Myrobalana*. Grafts made on stocks of the Wild Cherry soon go back. Specimens for forcing should have been previously grown in pots for several years, otherwise the result will not be satisfactory. During the first year they should be pruned so as to form a head; after this, they should not be further pruned. They should be placed in a room sheltered from frost for some weeks, having been previously exposed to frost, and should not be brought into the warm room before January or February, then they will soon come into bloom. They may be forced several years in succession. *Prunus Avium fl. pl.* is of little value for forcing.

**Prunus Padus, L. (Cerasus Padus, D. C.)**—This species is not so good for forcing in a room, as the specimens grow to too great a size before they come into flower; however, shoots cut and kept with the ends in water during the summer will bloom in December or January, and with greater success in proportion to the coldness of the water. Accordingly it will be found the best plan to throw a piece of ice into the vessel every day.

**Ribes sanguineum** and **R. speciosum**.—Of the numerous species of the genus *Ribes*, only these two North American kinds can be recommended for forcing. Of the first, which produces its deep red flowers in clusters, like the Currants, there is also a variety with double, and one with white flowers. *R. speciosum* more resembles the Gooseberry in its habit, but grows taller and has blood-red flowers. For both, the treatment, pruning, and propagation are the same as for *Diervilla rosea*. In forcing, they should not be placed in the warm room, but should be kept in a cool sunny one, with a temperature of from 43 to 45 Fahr., and in fine weather should receive plenty of air. Specimens treated in this way will bloom in the beginning of April, and may be forced annually for some years.

**Robinia hispida**.—This favourite ornamental shrub is distinguished by its large and handsome clusters of flowers. For forcing, specimens grafted on *Robinia Pseudacacia*, which have been potted for at least a year, should be selected, and placed in a cool room in January. They are afterwards removed to the warm room for flowering. In cold climates, where the wood does not ripen sufficiently, they do not answer for forcing.

**Roses**.—The Rose is one of the most favourite flowers in almost every room-garden. The continuously blooming kinds (*Rosa indica* and its varieties, to which may be added the Tea Roses and *Rosa Lawrenceana*) succeed best on their own roots in a cool double window, where they bloom in winter frequently better and more abundantly than in the plant-house. The best of the so-called continuously blooming kinds, or the hybrids raised between *R. centifolia* and the varieties of *R. indica*, should not be forced on their own roots, but specimens budded on the Briar should be employed. They should not be budded on stocks taken directly from the woods, but only on stocks of *R. canina* which have been grown in nurseries or on *Manetti* stocks. The stronger and the better rooted the stocks are the better will be the result. In spring the cultivators should obtain from a nursery dwarf worked specimens, grow them on through the summer in pots, and treat them on the same principles as the other woody plants which are recommended for forcing. They should not be pruned in summer, with the exception of the suckers on the stock, which should be removed, and in spring the pruning should be limited by cutting back the shoots to strong buds. After blooming the plants should be kept dry and treated for the ripening of the wood like other shrubs. After they have endured a little frost they should be removed into their winter quarters. From the beginning of December they should be placed in a room sheltered from frost and watered. All the superfluous shoots should be pruned away, and the rest cut back to two or three buds, according to their strength. When the buds begin to swell, the plants should be removed to the sunniest part of the room or into a double window, where they will have a temperature of from 43° to 48° Fahr. After the buds have started here the strongest specimens should be removed to a sunny window in the heated room, in order to bring them into bloom first. Those who wish to bud their own Roses should get some stocks from a nursery in spring, and pot them. In the end of July or the beginning of August they can bud them with dormant buds. The further treatment resembles that usually employed with all budded Roses, except that when they are placed in a cool room, the stocks should be cut off above the bud, if the bud has taken. They will

bloom abundantly in the first winter. After blooming, the plants should be placed in a well-lighted part of a room, sheltered from frost, and afterwards set in the open air. If necessary, they should be transplanted, and prepared for forcing again the next winter. They should be pruned either in spring, after blooming, or in summer. If possible, they should not be allowed to bloom a second time in summer, but should have their wood well ripened for winter flowering without being exhausted by a second blooming.

**Spiræa prunifolia, fl. pl.** and **S. Reevesiana fl. pl.**—Of all the numerous species of *Spiræa* recommended for forcing, these two kinds, which have double white flowers, are by far the finest. The treatment, propagation, &c., should be the same as those for *Deutzia*.

**Syringa chinensis, S. persica, and S. vulgaris**.—Next to Roses, the Syringas are more frequently forced than any other deciduous shrubs, on account of their handsome, luxuriant, and fragrant bloom. Specimens of *S. chinensis* and *S. persica* intended for forcing should be grafted on low standards. The best stocks are *Ligustrum vulgare* or *Syringa vulgaris*. The plants should be taken up in autumn with good balls, and potted in the same way as has been directed for other shrubs which are to be forced. They should not be pruned before forcing, unless they show too much wood, in which case the weakest shoots should be removed. In the middle of November they should be placed in a cool room, sheltered from frost, and in the first fortnight in December some of them may be removed to the warm room, for the earliest bloom. These will come into flower by Christmas or the beginning of the new year. If well taken care of, the same plants may be forced again after two years, but in order to secure a strong growth they should be closely cut back in the spring after they are forced. *S. vulgaris* is better for forcing in the form of large specimens in plant houses than for rooms. Shoots of it, however, cut in the middle of December and placed in water will bloom well.

**Viburnum Opulus, var. roseum**.—Plants of this intended for forcing in winter should be taken from the nursery in the previous spring and potted. They are as easily forced as Syringas, and may be placed in a cool room at the same time, and also later on in a heated room. When placed in a cool room, the summer's growth should be cut back to a few buds.—*E. Regel.*

## CAMELLIAS IN WINDOWS.

A CORRESPONDENT of the *Farmer* gives the following encouraging account of his experience with Camellias as window plants:—I had capital success with Camellias last winter. These are generally failures in the dwelling-house, as the buds drop just about the time they should open. The window of an upper hall was devoted to Camellias and a few other plants; twice during the winter the earth in the pots froze, and twice they were removed to a warm room to prevent freezing. In February the buds began to show signs of opening, and such plants as were ready to flower were taken to the dining-room, where they rapidly came into full bloom. Those who have no greenhouse can have Camellias, if they will only take a little trouble; and so magnificent a flower is worth a great deal of trouble. Nice, moderate-sized plants can be bought at from 5s. to 15s., and upwards. Keep the plants out of doors in a shaded place all summer, taking care that they do not get too dry and that no insect eats the leaves. I don't know what one it was, but some insect disfigured the leaves of one of my plants. When frosty nights come, remove the plants to the house, to a room without a fire, and keep the window open whenever it is not too cold. Water is needed, and during the winter wash the leaves with a sponge or soft cloth every week or two. A moderate freezing will not hurt the plants, unless the buds are too far advanced; but it is easy to prevent it altogether by removal to a slightly warmer place during very cold nights. As soon as the buds swell enough to show the colour of the petals, the plants may be removed to a sitting-room where their flowers can be enjoyed. Soon after the flowers have fallen, the Camellia makes its wood growth. At this time it may be repotted, giving it fresh soil in the same pot, if a cramped condition of the roots does not show that a larger one is needed. Fresh soil, such as decomposed sods, is as good as any of the mixtures of peat, sand, and other things recommended by the books. Prune into shape if necessary, and the plant will push its new shoots and grow rapidly. During the time it is growing, give it plenty of water and all the light possible. Set the plants in the open air as soon as frosty nights are over. The treatment is simple enough, and the success most gratifying.

**The Forget-me-Not**.—It is not sufficiently known that the summer Forget-me-Not will root in any vessel of water in a dwelling house, and if kept in a good light will go on flowering for a long time in succession.—*W. S.*

THE FRUIT GARDEN.

COMPARATIVE POPULARITY OF DIFFERENT KINDS OF HARDY FRUITS.

SOME time ago Mr. R. Varden, of Pershore, suggested to us the desirability of getting lists showing the proportions of hardy fruit trees raised and sold in various parts of the country. Such lists Mr. Varden rightly considered would be a good index to the kinds found to be most suitable in each district; and thanks to the courtesy of Mr. Richard Smith, we are now enabled to give the comparative numbers of one of the finest collections of hardy fruits ever brought together, of which in all 60,000 young trees are trained every year. The numbers represent the rows in which the trees are planted, and these rows are, for purposes of convenience in cultivation, exactly of the same length throughout the nursery, and each contains the same number of plants.

APPLES.

Table listing various apple varieties such as EARLY KINDS, MEDIUM SEASON, and LATE KINDS, with their respective counts.

CHERRIES.

Table listing various cherry varieties such as EARLY LYONS, MEDIUM SEASON, and LATE KINDS, with their respective counts.

NECTARINES.

Table listing various nectarine varieties such as ALBERT VICTOR, BALZOWAN, BOWLEN, CRICKET, DOWNTON, EARLY NEWINGTON, ELRUGE, HARDWICKE SEEDLING, HUNT'S TAWNY, LARGE ELRUGE, LORD NAPIER, MURRAY, OLD NEWINGTON, PINE APPLE, PITMASTON ORANGE, PRINCE OF WALES, RIVERS' ORANGE, ROMAN, STANWICK ELRUGE, VICTORIA, VIOLETTE HATIVE, and WHITE.

PEACHES.

Table listing various peach varieties such as Abec, Acton Scot, Alexandra Noblesse, Barrington, Bellegarde, Bourdine, Canary, Chancellor, Comet, Crinon Galande, Crawford's Early, Degmar, Dr. Hoeg, Early Alfred, Early Anne, Early Albert, Early Ascot, Early Beatrice, Early Grosse Mignonne, Early Louise, Early River, Early Savoy, Early Silver, Early York, Early Victoria, Golden Purple, Golden Rathprie, Gregory's Late Peach, Grosse Mignonne, Hale's Early, Late Admirable, Lord Palmerston, Lady Palmerston, and Magdala.

APRICOTS.

Table listing various apricot varieties such as Alsace, Beauge, Bresla, Brussels, Camino Grosso, De Milan, Early Moor Park, Gros Rouge, Henskerk, Kaisha, Large Early, Moor Park, Muech-Muech, Oullin's Early Peach, Peach (Gros Pêche), Roman, Royal, Royal Orange, Sluip's (Blenheim), St. Ambroise, and Turkey.

PEARS.

Table listing various pear varieties such as Belle de Bruxelles, Beurree de l'Assomption, Beurree Giffard, Citron des Carmes, Clapp's Favourite, Doyenné d'Été, Jargonelle, Rokeby, Souvenir du Congrès, Williams's Bon Chrétien, Bishop's Thumb, Chautauont, Comte de Lamy, Dana's Hovey, Délices de Jodoigne, Deux Sœurs, Doyenné Bonsoeck, Dr. Tronseau, Duchesse d'Angoulême, Durandean, Émile d'Alcy, Eyewood, Figue d'Hiver, Fontaine de Noël, Forelle, Gansel's Bergamot, Gansel's Bergamot, Gratin, Haeon's Incomparable, Hesse, Jalonsie de Pontenay, King Edward's, La Sœur Gregoire, Louise Bonne de Jersey, Maréchal de la Cour, Marie Louise, Marie Louise d'Uccle, Messire Jean, Napoleon Bonaparte, Nouveau Poitevin, Paradis d'Automne, Passe Colmar, Pitmaston Duchess d'Angoulême, Beurree Hardy, Beurree Bose, Beurree Clairgean, Beurree Diel, Beurree Berckmans, Beurree d'Aremberg, Beurree Brown, Beurree Dabaume, Beurree Sterckmans, Beurree Millet, Beurree Léon Le Clerc, Gisborne's, Golden Gage, Golhath, Green Gage, Guthrie's Aunt Anne, Guthrie's Late Green, Hubing's Superb, Ickworth Impératrice, Imperial Ottoman, Imperiale de Milan, Joffre's, King's Golden Drop, July Green Gage, Kirke's, Late Orleans, Lafayette, Lawrence's Gage, Liegel's Apricot, Mamelonne, M'Laughlin's Gage, Mimer, Mirabelle Petite, Michelson's Damson, Nectarine, Nonsuch, Orleans, Oullin's Golden Gage, Peach Plum, Pond's Seedling, Pompart's Plum, Prince Englebert, Prince of Wales, Prune Damson, Purple Gage, Reine Claude Bonum, Reine Claude Bodart, Reine Claude de Bavay, Reine Claude Rouge, Reine Claude d'Octobre, Reine Victoria, Royal Hative, St. Etienne, St. Martin's Quetsche, Standard of England, Transparent Gage, Victoria, Washington, Webster's Gage, White-MagnanBonum, Woolston Black Gage, and Winesour.

PLUMS.

Table listing various plum varieties such as Angelina Burlett, Autumn Compote, Belgian Purple, Belle de Louvain, Belle de Septembre, Blue Impératrice, Brandy Gage, Brully's Green Gage, Bryanston Green Gage, Clufter Damson, Cox's Golden Drop, Cox's Emperor, Cox's Nota Bene, Cox's Late Red, Dequiste, Demistone's Superb, De Montfort, Diamond, Dove Bank, Downton Impératrice, Drap d'Or, Early Favourite, Early Prolific, Early Orleans, Feltenberg, Gisborne's, Golden Gage, Golhath, Green Gage, Guthrie's Aunt Anne, Guthrie's Late Green, Hubing's Superb, Ickworth Impératrice, Imperial Ottoman, Imperiale de Milan, Joffre's, King's Golden Drop, July Green Gage, Kirke's, Late Orleans, Lafayette, Lawrence's Gage, Liegel's Apricot, Mamelonne, M'Laughlin's Gage, Mimer, Mirabelle Petite, Michelson's Damson, Nectarine, Nonsuch, Orleans, Oullin's Golden Gage, Peach Plum, Pond's Seedling, Pompart's Plum, Prince Englebert, Prince of Wales, Prune Damson, Purple Gage, Reine Claude Bonum, Reine Claude Bodart, Reine Claude de Bavay, Reine Claude Rouge, Reine Claude d'Octobre, Reine Victoria, Royal Hative, St. Etienne, St. Martin's Quetsche, Standard of England, Transparent Gage, Victoria, Washington, Webster's Gage, White-MagnanBonum, Woolston Black Gage, and Winesour.

From the above list, one may get a clear idea as to the relative value at present set upon any hardy fruit in the great Worcester district in which so many of them have been well tried.—Field.

## THE FORM OF FRUIT TREES.

WHAT is the object of an orchard? It is to raise fruit; and to raise it successfully there must be a wide extent of the tree exposed to sun and air. To do this a high or a low head will do about equally well—perhaps a little better if raised, as it gives more advantage of air and sun, and less moisture. The best form of a tree-top (we have reference here more particularly to Apples) is an elongated one—this in addition to the usual side extent, or otherwise. If the diameter is great it requires wide planting apart, which, though the space may be cultivated for some other crop, were better furnished by the legitimate crop. By lessening the length of the side branches, and directing the growth to the length or upright direction of the tree, more trees may be planted on the same area, and still the same superficies of the tree secured. I have seen some remarkably high trees, branches reaching down to the ground, the trees yielding enormously of good fruit, and yet not overcharged, the branches gently bending with the fruit; being numerous, they could afford to bear a thinly distributed yield, which is always a safe, and may be made a yearly yield.

We want another thing—an undulating instead of an even or roof surface. This indentation of the surface gives more exposed space, which is wanted for the ripening and perfection of the fruit, as well as its growth. To give this increase of surface, it needs but space between the branches, instead of a close, even surface, admitting no sun, and little air. Of course no fruit is raised inside this close surface. The top of such a tree is, as we usually find it, like an inverted cup, and is always a breeder of mischief where the branches reach the ground. Now, there is a certain beauty in a tree with the concave top set on the ground, the outside being an even, roof-like surface, covered with fruit and leaves—fruit highly coloured and well grown. But it suggests monotony. It also bears less fruit, and of a less excellent quality.

Take now the other top—the same form a little elongated, the branches showing distinctly, giving a diversified surface, which relieves the eye, and adds grace and beauty to the tree. Each branch is a sort of tree in itself, joined to the one stem. Here you have health, perfect ventilation, and access of light; in consequence you have an unmatched quality of fruit, as well as an increase of quantity, and that without straining the tree, the fruit-bearing surface being greater. You have a top here that can probably not be improved. All the excellences unite here. You get, let me repeat, the most fruit from the tree and from the same ground; you get better fruit; you strain the tree less in its production, and you have a healthier growth, both of wood and fruit.

Shall there be a high or a low head? This is a mere matter of taste or option with the owner, influenced somewhat by circumstances. If it becomes necessary to cultivate the ground, a very low head will be in the way. In a moist season a low, close top will certainly work mischief; Moss and mildew will appear: fruit will be rusty. It will be less so where elevated and exposed to the air. A high head requires a long ladder to secure the fruit. It also exposes more surface to the wind; but in an orchard, where the trees, as in the forest, protect each other, this somewhat loses its force. Let the branches be distinct, with spaces between for sun and air. Our best trees have touched the ground, here and there a branch, when heavy laden; and with a diversified surface extending far up there was as fine a sight as could be wished for—gracefulness, variety, and a wealth of rich, highly-coloured fruit. There are several advantages in the elongated top that cannot be overlooked. There is the space above, which is unlimited; all the growth which the roots will allow may here find room. No lack of space, as with the side growth so often.

CULTIVATOR.

## NOTES AND QUESTIONS ON THE FRUIT GARDEN.

**Vines in Pots.**—I have 60 Vines in pots, covering the roof of an early house with the finest foliage, showing, after having been disbudded, from 25 to 30 bunches, just expanding their flowers. Is not this much better than thus early disturbing permanent Vines?—R. GILBERT.

**Prizes for Fruit.**—The prizes offered by Messrs. Veitch & Son for fruit are worthy of all praise. I hope and believe they will receive a hearty response. With respect to the prizes for Pines, I would suggest that such varieties as Black Jamaica and Ripley Queen should take the place of Providence and Charlotte Rothschild, which are large but coarse, and of very indifferent flavour; in fact only sorts for "show," and not worth growing.—R. GILBERT, *Burghley, Stamford.*

**How to make Vines break their lower buds.**—Early forced Vines, especially pot Vines, are generally disposed to break their top buds, or the latest formed ones, first. A sharp bend, by tightening the tissues and arresting the ascent of the sap, will cause the lower buds to break—at least those immediately below the bend; but twisting the cane regularly its whole length checks the rush of sap through the tissues more effectually, and causes all the buds to break. Another good plan is to keep the bottom part of the cane near the pipes and the top away from them and comparatively cool. I have often adopted this plan with long vine rods of one year's growth, and have always found it to be successful.—J. S.

## THE ARBORETUM.

## FREMONTIA CALIFORNICA.

AMONGST comparatively recent introductions to our outdoor gardens, few are more ornamental than *Fremontia californica*, a fine shrub, named after Colonel Fremont, who discovered it in the northern part of the Sierra Nevada, during one of his Californian expeditions. In its native habitats it seldom reaches more than 10 feet high, and has considerable resemblance to a Fig tree in the construction of its leaves. They are, however, less robust, of a bright shining green colour above, and tomentose underneath, three, five, or seven lobed, the lobes collectively forming a roundish outline. They are about 3 inches in diameter, and are supported on petioles of about the same length. The accompanying illustration, taken from a mere twig, gives but a faint idea of the beauty of this shrub or of the size of its leaves. The flowers are bright yellow and are produced singly at the extremities of short spur-like branches; they consist of a widely campanulated calyx, immediately under which are three small lanceolate bracts. One of the finest specimens of this plant in Britain is in the nurseries at Coombe Wood. It was raised from seeds sent home to Messrs. Veitch from California by Mr. W. Lobb. It is planted against the wall of one of the glass houses, where it has remained uninjured for several years, and produces annually in May and June a profusion of golden blooms. It seeds freely, but in this country the seeds have not as yet ripened. It likes a well drained good loamy soil, not too retentive, stagnant water in winter being its worst enemy.

Besides being treated as a wall plant, it is likewise grown in the form of isolated bushes in the same nurseries, protected in winter with a hoop and mats. It is evident, however, that a south wall in a well sheltered position is its most suitable English home. Where the severity of climate would kill it in winter it might be kept indoors, and planted out in April or May, or it might with advantage be grown permanently in a cool conservatory.

WM. FALCONER.

## CONIFERS AT CASTLE KENNEDY.

FOR fully twenty-four hours I had been travelling north-north west, and found at the end of my journey avenues of *Araucaria imbricata* nearly half-a-mile in length, averaging about 30 feet high, of *Picea nobilis* avenues longer still, and of nearly the same height. Many of the *Piceas* were heavily laden with cones full of prime seed. Avenues of *Pinus insignis*, as green as grass, and from 30 to 40 feet high; and others of *Picea Pinsapo*, *P. cephalonica*, *P. Nordmanniana*, *P. Webbiana*, *P. lasiocarpa*, &c.; *Pinus laricio*, *P. austriaca*, *P. excelsa*, *Abies orientalis*, *A. Albertiana*, and *A. Morinda*, *Cupressus macrocarpa*, *C. Lambertiana*, *C. Lawsoniana*, *Thuja Lobbi*, *Cryptomeria japonica*, *Taxodium sempervirens*, *Cedrus Deodara*, *C. Libani*, and many others; while the avenues were backed in many instances with such masses of *Arbutus*, *Laurostinus*, Sweet Bays, variegated Hollies, Laurels, *Rhododendrons*, and *Fuchsias* as one hardly expects to find unless in the south of England or Ireland. Many of the Sikkim *Rhododendrons* are quite hardy at Castle Kennedy. The *Hydrangea* forms bushes in the open air, as in Devonshire; while one of the *Eucalyptuses* from Australia has stood in the open air for several winters. The whole place forms a sort of peninsula between two lochs of great extent; and to this and its proximity to the sea the comparative mildness of the climate is no doubt due. This mode of planting in avenues is also somewhat favourable for shelter. The lines run in various directions, thick blocks of common trees or choice shrubs are packed in as buffers between the avenues, and break the force of the wind. These buffers are indeed much needed, for the winds are terrific, sometimes breaking trees right off, and at others tearing them out by the roots. Other trees, such as the *Wellingtonia gigantea*, *Taxodium sempervirens*, and even the *Cedrus Deodara*, make little progress, unless in the most sheltered positions; whereas the *Araucaria*, *Picea nobilis*, *P. Pinsapo*, *Pinus excelsa*, *P. laricio*, *P. austriaca*, *Cupressus Lambertiana* and *macrocarpa*, and even the *Arbutus*, Sweet Bays, and *Laurostinuses*, seem to brave and defy the wind at its worst. Again, such Pines as *P. Benthami*, *P. Coulteri*, and even *Picea Webbiana*, seem to shrink from the wind and grow slowly. The following are among the more notable and freest-growing species and varieties at Castle Kennedy: *Pinus muricata*, *P. Hartwegii*, *P. resinosa*, *P. insignis*, *P. laricio*, *P. austriaca* (these three last are the freest of all); *P. tuberculata*, *P. rigida*, *P. pyrenaica*, *P. patula*, *P. Edgariana*; *Cupressus*, the two already named, and

FREMONTIA CALIFORNICA.

1. Plan of the flower. The ovary should have been represented as 5-celled.—2. The androecium, magnified.—3. An anther, with the free portion of its filament magnified; front view.—4. The same; side view.—5. Transverse section of an anther, showing the twisted loculi of each cell.—6. Pistil, considerably magnified.—7. Longitudinal section of a flower, only part of the calyx remaining, equally magnified.—8. An ovule, more highly magnified.—9. One of the stellate hairs, highly magnified.

Lawsoniana in many varieties, *C. thurifera*, *C. tornosa*, *C. McNabiana*, and others. Most of the Junipers thrive well, as also *Cryptomeria japonica*, *C. elegans*, and *C. arancarioides*. *Thuja gigantea* is a fast-growing tree, and all its varieties do well. The progress made by all the trees is astonishing when we look at the bleak and exposed position, and reflect that the largest of these Conifers were not planted till 1817, and most of them at periods long subsequent. The charming *Retinospora* and other novelties from Japan are now being planted. If a tree or shrub does well, it is multiplied as fast as possible, and grouped, dotted, and planted in avenues by the hundred or thousand. If it merely consents to live, it is preserved as an object of interest, but not greatly multiplied. In this very valuable information is collected, and trees most suitable for given purposes and localities discovered. *Picea nobilis*, *Pinus austriaca*, *Pinus laricio*, *Cupressus Lawsoniana*, and others, are looked upon as valuable timber trees. They far outstrip the common Spruce, Larch, or Scotch Fir on their own ground. But this rapid growth is not favourable for timber. Quick grown Cedars of Lebanon make softer deal than slower grown Scotch Fir. Still it is a great thing in a landscape to see the trees of other lands grow so freely, and intermingle the tints of their foliage and their endless variety of form with the trees of our native country, as they do in the well-planted and well-kept grounds at Castle Kennedy. F.

#### ROAD-SIDE TREES AND TELEGRAPH WIRES.

LET me advise your correspondents who have suffered from the mutilation of their trees to appeal to the law for protection. In the case of a parish road, I feel no doubt the proprietor of the adjoining land can compel the removal of telegraph posts if injurious to him, as he still retains the freehold of the land, and the public rights are limited to the use of it for the purposes of a road. Under any circumstances, an action would no doubt lie against the Post Office for damage to the trees, and probably the man who cut them would be liable to summary proceedings before a magistrate under the "Wilful Damage Act." A COUNTY MAGISTRATE.

#### SCOTT AS A LANDSCAPE-GARDENER.

SIR WALTER, writing from Edinburgh to William Laidlaw, his friend and agent at Abbotsford, says—"You must get some one to stick in a few wild Roses, Honeysuckles, and Sweet Briars, in suitable places, so as to produce the luxuriance we see in the woods which Nature herself plants. We injure the effect of our planting, so far as beauty is concerned, by neglecting underwood. . . . I want to know how you are forming your glades of hard wood. Try to make them come handsomely in contact with each other, which you can only do by looking at a distance on the spot, then, shutting your eyes as you have done when a child looking at the fire, form an idea of the same landscape with glades of woodland crossing it. Dismiss your ideas about expense. If I were to buy a picture worth £500 nobody would wonder much. Now, if I choose to lay out £100 or £200 to make a landscape of my estate hereafter, and add so much more to its value, I certainly don't do a more foolish thing. I mention this that you may not feel limited so much as you might in other cases, by the exact attention to pounds, shillings, and pence; but consider the whole on a liberal scale. We are apt to consider plantations as a subject of the closest economy, whereas beauty and taste have even a marketable value after the effects come to be visible. Don't dot the plantations with small patches of hard wood, and always consider the ultimate effect."

It is pleasant to see from the Laidlaw manuscripts how the friends of the poet came forward with kindly contributions; the Duke of Buccleuch sent bushels of Acorns, the Earl of Fife presented seed of Norway Pines, Lord Montagu forwarded a box of Acorns and a packet of Lime seed. One arboriculturist sent seeds of the Corsican Pine, then got with difficulty, and also two or three of a species which grew to a great height on the Apennines. Dr. Graham reported that they should be raised in finely prepared mould under glass, but without heat. A box of fine Chestnuts came from Lisbon; the box was, however, sent on from Edinburgh to Abbotsford unopened, and before Laidlaw heard of them the Chestnuts were peeled, and of course rendered useless for planting. One object was to form an impenetrable copse or natural hedge, or verdurous screen, all epithets used by the poet (Milton has "verdurous wall"), and for this purpose there were sent from Edinburgh 3,000 Laburnums, 2,000 Sweet Briars, 3,000 Scotch Elms, 3,000 Horse Chestnuts, loads of Hollies, Poplars for the marshy ground, and Filberts for the glens. The graceful Birch tree, "the lady of the wood," was not neglected. "I am so fond of the Birch," writes the poet, "and it makes such a beautiful and characteristic underwood that I think we can hardly

have too many. Besides we may plant Birches as hedges." He therefore purchased at this time about 100,000 Birches.

"There are many little matters relating to the walks," writes the busy and happy laird, "which, though some concern them, are not less necessary towards comfort; a seat or two, for example, and covering over drains. In front of the old Rispylaw is an old quarry, which, a little made up and accommodated with stone seats and some earth to grow a few Honeysuckles and Sweet Briars, would make a very sweet place." In another letter to Laidlaw, he says:—"I have got a new light on Larch planting from the Duke of Athole's operations. He never plants closer than 8 feet, and says they answer admirably. If this be so, it will be easy to plant our hill-ground. Mr. Morrill, of Rokeby, writing to the Hon. Mrs. Stewart Mackenzie, says:—"He (Scott) tells me that he never was so happy in his life as in having a place of his own to create. In this Caledonian Eden, he labours all day with his own hands."

But a small number of the visitors that throng annually to Abbotsford ever think that the woods and wilds around it owe their origin to the creative genius of Scott. These extracts may, therefore, tend to throw some light upon the matter. The interest belonging to every tree and shrub around that romantic building will be greatly enhanced by the knowledge that it has been planted and reared under the direction of the great romance builder himself. As we note the different kinds of Ivy creeping up the gray walls of the mansion, we feel almost sure that they have been planted there by Scott's own hand; perhaps sent to him by friends who knew how acceptable plants of rare and variegated Ivies would be to the man whose soul was in such intimate unison with nature. All who visit Abbotsford may see at a glance the natural difficulties under which Scott laboured to make his place either beautiful or romantic. True he had the Tweed as a groundwork for his great natural picture, but he was on the wrong side of the river, and a high road ran very near the mansion. Still the planting and treatment of the grounds about Abbotsford are better worth inspection than even the chair where sat the man who could paint and penitry nature so well in all her varied aspects, and on which visitors yet gaze in silent wonder. J. T.

**American Black Walnut.**—A correspondent of the *Builder* directs the attention of architects and cabinet makers to the value and beauty of black American Walnut wood. "My attention," he writes, "was first directed to its use by an accident; and during now a period of seventeen years I have tested its durability and adaptability for almost every kind of woodwork. I have had it used for the largest and most costly kinds of furniture, with carvings of the most elaborate kind. I have had it used for doors exposed to the full action of the weather; for conservatory doors, exposed to constant damp and considerable changes of temperature; for a large and costly staircase, the whole of the walls being covered with the same wood, and the floors of the same; for internal doors and casement windows, of rather large and costly construction, and carved, and for every kind of small cabinet work, exhibiting the highest taste and good workmanship; and for all these purposes I have found the wood answer most admirably. It appears to bear rough external wear quite as well as Oak. It does not warp or crack like Oak, and bears the greatest transition of heat and cold without any visible change. The colour of the wood, when oiled, is perfect—that natural rich brown colour which three centuries of wear will alone give to Oak; it has a close grain, without much figure; it is thoroughly well adapted for every kind of carving; and its cost now is not higher than Oak. It is to me surprising that for every species of good church-work it is not used. It has every possible advantage over Oak, and in old cathedrals requiring new stall-work its rich brown colour would give it a great advantage over the pale brown yellowish hue of new Oak—which, to my own taste, is most offensive. After great experience, I know not one drawback to the use of black American Walnut; and want of knowledge of its many excellent qualities has, I am sure, alone prevented its more general use."

**Neglecting Young Trees.**—I have lately been looking over some old bills which I have had from various nurserymen, and am astonished to find the quantities of Pines and other specimen trees which I have had from them during these last dozen years; and where are they now? Some few have been destroyed by ground game; but the main quantity, having been guarded, where lost have been choked by the Grass and Brambles. You come upon a suitable place for a specimen, and get a Pine or a Wellingtonia, as the case may be, out of your little nursery, which no estate should be without, and think to yourself, "Now I'll look after this tree and see that it gets fair play." A couple of years pass, and accidentally you tread the same path. Your memory is jugged by seeing either a brow, dead stem, or a poor creature struggling for

its life in the midst of a mass of Brambles, growing all the more luxuriantly for the stirring of the ground. I intend in future to keep a book, enter all specimen trees in it, marked when and where planted, and have them looked to twice in a summer. Of course in a large place your forester should look to these things; but, after all, I doubt if he does, and the waste of trees and time goes on. I find *Picea grandis*, *P. nobilis*, and *P. Nordmanniana* do better with me on the Yorkshire hills than anywhere. Curiously enough, I have great difficulty in getting the common Silver Fir, *Picea pectinata*, over the first few years, owing to spring frosts cutting down the leader. If once established, they do well.—*A Soldier.*

HARDY TREES AND SHRUBS.

BY GEORGE GORDON, A.L.S.

THE MOUNTAIN MAPLE (*ACER SPICATUM*.)

THIS forms a neat, small, deciduous tree, from 15 to 25 feet high, with rather an open and somewhat spreading head, furnished with slender brown shoots, and in the autumn, when garnished with its numerous small keys, with thin membranous wings beautifully tinged with red, and fixed upon slender pendulous spikes, it forms a very ornamental object. It is a native of North America, on the mountains from Canada to

*A. spicatum.*

Georgia, and was first introduced in 1750. The leaves are rather below the middle size, and three or slightly five-lobed, with the three outer ones acutely pointed and the largest. They are irregularly and coarsely serrated on the edges, cordate at the base, and, when full grown, deep green and smooth on the upper surface, downy and pallid beneath, and on long, slender, bright red footstalks, and, just before they fall off in the autumn, turn to a yellowish-red colour. The flowers are small,

Key of *A. spicatum*.

greenish-yellow, and produced in great abundance in many-flowered, erect racemes in May. The fruit or keys are small, quite smooth, and produced in pendulous racemes, and when nearly ripe, tinged with red; the carpels are thick, and the wings rounded at the ends, and somewhat spreading. The synonyms are *Acer montanum*, *parviflorum*, and sometimes *Pennsylvanicum*. Length of full-sized leaf, 6 inches, including the footstalk, which is  $2\frac{1}{2}$  inches, and the breadth 4 inches.

**Briar-wood Pipes**—The well-known wooden pipes, used by smokers, are made from the root of a plant called the Briar-Ivy, which is a species of *Smilax*, found growing throughout the Southern States of America. The best qualities grow in Virginia. It comes to market in pieces the size of a small keg, and is worth £10 per ton.

BLUE COLOUR OF THE LAKE OF GENEVA.

M. COLLAS (see p. 558, Vol. II.) attributes the blue colour of the lake of Geneva and of other waters to the quantity of siliceous matter held in solution, which is brought down by the tributary streams from the strata through which they pass. He is stated to believe, also, that the blue colour of all the water of the globe is due to the same cause, statements from which I beg to dissent.

In the first place, as to siliceous matter or flint, one may naturally surmise that the blue water of the Lake of Geneva and of the Rhone as it leaves the lake are far less charged with that substance than the Rhone when it enters it at Villeneuve, loaded with the detritus of the glacier's stony bed, and yet, there, it has no symptom of blue. Then as regards glass; although the quantity of siliceous matter in crown glass, flint glass, crystal, and strass varies a good deal, yet those sorts that contain the most siliceous matter have not a bluer tint on that account; in fact, their colour is only materially affected by the amount of iron or of manganese that is put into them. A common-place view of the subject would be this:—Air, as well as the waters of the lake of Geneva, of the Mediterranean, of the deep sea in the ocean commonly called "blue water," of the Rhone, the Meselle, and other rivers; the deep ice in the Swiss glaciers, and icebergs at the Poles, are all perfectly transparent mediums; and taken in small portions, such as a glass of any of these waters, a lump of any of these ices, or a few square inches deep of air, are, to all intents and purposes, perfectly colourless, and in no way affect the appearance or colour of any illuminated body seen through them. But if the depth of the column of these mediums be greatly increased, accordingly as it augments, will the object seen through them put on more and more of a bluish tint—be it a pebble at the bottom of the Rhone, a stone imbedded in clear, thick ice, or a mountain far away on the horizon; the appearance in the latter case being designated by painters as "aerial perspective." If the column be continued deeper still, objects at last become invisible, and the blue tint covers all. What, then, is the cause of this blue, if we will not allow, as Messrs. Collas & Lallemand do, that it is owing either to siliceous matter or to the absorption of certain particular rays? Without going into any very erudite technicalities, we would say that the colour is owing to a black, *i. e.*, an unlighted background seen through an illuminated transparent medium; for all these mediums are not only transparent, but their component particles reflect light. We will not here inquire whether chemically dried air reflects light or not, and whether air, even in the driest countries, only reflects light because of the water it contains. Suffice it that everywhere in nature it does so, and that for that very reason, and because the particles of ice, water, and air, break up and reflect the rays of light in all directions, those rays can only penetrate them to a certain depth, then comes a point they fail to reach, and that this limit is of course dark, in other words "black," be it the "outer darkness" beyond our atmosphere looking up, or certain strata deep in the sea or the river, looking down. And it is this black seen through the illuminated mediums, or what natural philosophers call diffused light, which conveys the sense of blue to the eye. When the sun goes down this blue becomes deeper and the blue vault would become an "inky one," but for the moon and stars that still light up the medium a little; the transparency is still there, and through it we perceive the black background growing nearer and nearer, according as the rays of light penetrate less and less deep into the atmosphere, and finally vanish with the orb that emits them. If we go out on a dark night with a lantern, the black background encircles us within a few feet, and whether an inch beyond that circle there exists a white wall, or a red curtain, or 100,000 miles of space, it is all one to us. The very forcible epithet of "tangible darkness," according to our notions, appears a very true one, as applied to a very dark night. The black vault of "outer darkness" has come down to our brow, and the black bottom of the ocean has risen to our feet, and whatever we put our hand upon is black, and we are bathed in it; it hems us in on all sides. Morning sends all this black wall back again down far below the surface of the sea, upwards far above all earthly ken, away around us further than human eye can reach. It is still there but toned down

into that lovely hue which we so much admire in the sky, the water, and the glacier. And where ice and air and water have not this lovely hue it is that they are not transparent and limpid, and either soiled by extraneous matter or actually coloured by some vegetable or mineral pigment, or reflect the hues of seaweed-covered rocks, as in many an emerald green estuary on the western coast; or in the case of the atmosphere, are so filled with vapour that they shut out the background completely.

FREDK. PALMER.

*Versailles.*

### FLOWERS FOR HOSPITALS.

We are leaving home, a country home, and going through London. We have heard that in hot July weather, home-sick folk in London hospitals hanker after flowers from the country, yearn after Thyme and Lavender, and Wallflowers, and Balm of Gilead. We have got some of these, we will pick them as it is a fine morning; and our Roses will only fade unseen, so we may as well pick them. We will have them put in a hamper, and take them vaguely up to London. When we arrive at King's Cross, we ask what hospitals we pass between that and Paddington? "Hospitals?" says the porter astonished, surveying us to see whose fate it is to be left stranded at "any hospital" between this and Paddington. "There are no hospitals," he replies.

There is no time to be lost, so we sigh, give our hamper a push back on the sloping cab-seat and drive on. But we are bent on doing good now that we have had all the trouble of picking the flowers; besides, we want to get rid of the hamper, which slips irritatingly forwards, and is as often pushed back to its place. So we keep a sharp look-out. Very soon in Marylebone Road we come upon some objects of our search. When we have passed one or two large buildings, "supported by voluntary contributions," we begin to be fastidious. We will not give promiscuously to any charity, but will find one we fancy. And we fix upon the Cripples' Home. Shall we get out, or shall we leave the hamper? We will get out, and just see how the experiment answers. The lady superintendent is smiling at the door; we show her the flowers, and she smiles still more. We carry the hamper up to a large room, where about twenty poor cripples are working. We empty the hamper on to the table, and a great cry of "Oh!" prolonged almost into a sigh, is our thanks and greeting, while all the dull faces brighten at the sight of flowers that carry them back to home. May the superintendent ask our name? "Country friends," we say, and hurry off; we are still rather ashamed of doing good. We have enjoyed seeing those faces, and by getting out we have been able to bring away the empty hamper; and then a "happy thought" strikes us—we may do it again. We are quite sure it is a good thing to give away flowers to the poor: we could not allow them to come into our garden, oh, no! but cutting the flowers and giving them away (when we are leaving home and cannot enjoy them—especially) is another thing. We wonder whether the poor people would like a plant—a little country plant, that would get dusted over with London dust, and be watered every day, and kept in a dark corner? Perhaps, when we have got a step farther, we may not think it too much trouble or too much loss to send plants to the Cripples' Home or the Children's Hospital—pots included.

**Vegetation at Bethlehem.**—Cornfields and vineyards creep along the ancient terraces. In the spring the hills and valleys are covered with thin grass, and the aromatic shrubs which clothe more or less almost the whole of Syria and Arabia. But they also grow with what is peculiar to Palestine, a profusion of wild flowers, Daisies, and a white flower called the Star of Bethlehem, with a blaze of wild flowers of all kinds, chiefly Anemones, wild Tulips, and Poppies. Of all the ordinary aspects of the country, this blaze of scarlet colour is, perhaps, the most peculiar, and to those who first enter the Holy Land, no wonder it has suggested the tempting and significant name of "the Saviour's blood-drops." \* \* \* The "hill country," as it is called, of "Juda," in earlier, or "Judea" in later times, is the part of Palestine which best exemplifies its characteristic scenery. The rounded hills and broad valleys, the scanty vegetation, the villages and fortresses—sometimes standing, more frequently in ruins—on the hill tops, the wells in every valley, the vestiges of terraces, whether for corn or wine. \* \* \* Here, more than elsewhere, are to be seen on the sides of the hills the vineyards marked by their watch-towers and walls, seated on their ancient terraces, the earliest and latest symbol of Judah. The elevation of the hills and table lands of Judah is the true climate of the Vine.—*Steuale, J.*

## GARDEN STRUCTURES.

### HORLEY'S PATENT GARDEN FRAMES.

SPECIMENS of these were exhibited at Birmingham in June last by Mr. Horley, of Toddington, Beds. They are made of wood, glazed with 21 oz. glass, and put together with iron screw pins, in the manner of a bedstead, a wrench being supplied for that purpose. They are made in lengths 4 feet wide, so that any number may be placed together. The principal novelty in the construction of these frames is the method of fixing the glass, neither sash-bar nor putty being used; the squares, which are 24 inches by 16, are run into a groove at the top, and rest in a rabbet at the bottom, each pane being secured in its place by an iron button. To facilitate the removal of all or any of the squares, they are not allowed to lap, and a piece of webbing is fixed underneath each, by which they are easily raised. The examples which we saw at Birmingham were light and neat, and looked as if they would prove both useful and serviceable, a result which we learn

Horley's Garden Frames.

has been fully realised. They are well adapted for raising choice seeds or for striking cuttings, and they are so cheap that 32 square feet of ground can be covered by them for a sovereign.

### FRUIT TREE PROTECTORS.

YOUR correspondent, who signs himself "An Architect," has, I feel persuaded, merely taken a hurried glance at the illustration given at p. 474 of your last year's volume, without reading the letterpress. If he will procure my "descriptive catalogue" he will find that I have proposed the very thing which he recommends. I never intended that the trellis-work should be kept open winter and summer; such an idea would be absurd. He will find that "the sides and ends can be glazed within 2 and 3 feet of the ground, and that that space can be filled in with close woollen matting from Christmas to Midsummer." These houses are not intended to take the place of conservatories or plant-houses; they are simply "Fruit Tree Protectors," that can be put up by any country gentleman at small expense. I shall be willing to put this to a practical test at Chiswick or elsewhere, if "An Architect" is ready to share a portion of the expense. Models of my contrivances were shown last summer at the great Exhibitions at Birmingham, Cardiff, Dorchester, and Kelso, and they were considered by "one and all" to be valuable auxiliaries in the way of protection. Sir W. Forbes, Fintray House, Aberdeen, says in the *Aberdeen Journal*:—"With reference to the Peaches which gained the first prize at the horticultural show the other day, I may mention that they were simply protected by Rendle's Patent Wall Screen, and had no artificial heating whatever." W. E. RENDLE.

### RUSTIC ARCHITECTURE.

YOUR correspondent, "An Architect," is right about draughts (see p. 474, Vol. II.), and I marvel that he is so, for most architects are all at sea on this point, planning and building so that there is a draught in every portion of the room except up the chimney. But plants do not like being set in a draught, and I proposed, I think, that they should not be so in cold weather. When warm, even draughts may prove useful; for, singular as it may seem to "An Architect," rustic orchard houses may be turned to other and equally useful purposes besides that of forcing fruits, that is, they may be used to retard them. Peaches, Plums, and Nectarines may be more useful in the latter end of September and all through October than in July. The draught will enable us to keep these late. There is, therefore, no

doubt that these houses will prove serviceable. One or both sides may be glazed or curtained up at pleasure, thus placing draughts under control. There is, therefore, no need for a drifting sleet or snow-storm being allowed to drive in among the trees.

The great merit of all such temporary erections is that they afford shelter without disturbing the light, and I do hope that the rage for and popularity of cheap glass structures, such as those offered by Mr. Rendle, will induce horticultural architects in future to make it the first condition in all their works to provide a maximum amount of shelter with a minimum of shadow. If they will do that we will gladly welcome their taste and genius in helping us to make our light and efficient cultural contrivances more beautiful: for there is no doubt that cultural capacity, if I may so express it, ought to be compatible with structural elegance. I would invite architects to render us this service as some atonement for the past injuries their so-called plant houses used at one time, and still do even now sometimes, inflict on horticulture; for there is no doubt that our rage for light and craze for cheapness is leading us to overlook those characteristics that ought more or less to distinguish all permanent horticultural buildings, viz., stability, beauty of design, and perfection of execution and finish.

D. T. FISH.

## WORK FOR THE WEEK.

### PRIVATE GARDENS.

**Flower Garden.**—The unusual mildness of the season has brought out blossoms of Snowdrops, Violets, Daisies, occasional Narcissi, Pansies, a few Wallflowers, golden-leaved Feverfew, Christmas Roses, Primulas, both yellow and crimson, China and tea-scented Roses, *Jasminum nudiflorum*, *Chimonanthus fragrans*, *Laurustinus*, *Arbutus*, and others. It is only on the *Jasmine*, *Hellebores*, *Snowdrops*, and *Violets*, however, that flowers are really plentiful. If bulbous plants are so forward as to be likely to be injured by frost, should it come, top-dress the beds with leaves, ashes, or similar materials, among which cocoa-nut fibre is the neatest and best. Transplant trees and shrubs, repair and make walks, construct, reduce, or otherwise renovate rockeries, relay turf, and energetically proceed with all similar alterations. Sow Sweet Peas, and protect them at the same time from pheasants. Remove dead wood from climbers on walls and on pillars, and tie up healthy shoots. In wet weather prepare stakes for Sweet Peas, Dahlias, standard Roses, and similar plants. Examine Dahlia, Cannas, and other roots, removing from them all decaying portions, and keeping the sound roots dry and cool.

**Conservatories.**—Arrange foliage and flowering plants together effectively and harmoniously. Remove plants done flowering, and introduce a fresh supply from the forcing pit. Give a little weak manure water to Cyclamens. Keep late ones close to the glass in frames free from drip, and sow some seeds of Cyclamens in an intermediate house. Sow also a few seeds of East Lothian Stock; keep autumn potted Stocks in cold frames, and pot off a few of them singly. Pot any *Calceolarias* or *Cinerarias* that may require it, using a rich compost for them. Prune a few more pot Roses, and place them in a forcing house or early Peach house to induce them to come into bloom. In early Fig houses or other fruit houses not too much shaded many flowering plants may be brought into bloom, either for conservatory decoration or for cut flowers. *Rhododendrons*, *Roses*, *Callas*, *Tree Carnations*, *Heliotropes*, *Mignonette*, *Lily of the Valley*, *Tulips*, *Hyacinths*, *Narcissi*, *Kalmias*, *Jasmines*, *Weigelas*, *Prunus sinensis*, *Lilacs*, *Ghent and Indian Azaleas*, *Camellias*, *Fuchsias*, *Hippeastrums*, *Hæmanthus*, *Violets*, *Pelargoniums*, and several other plants might be flowered in early fruit houses, in which they should be arranged with discretion. Such as are soft-wooded should be kept as near the glass as possible, and hard-wooded deciduous plants should be placed by themselves so that they can be freely syringed. *Violets*, if planted out in frames on a bottom heat, afford more flowers than under any other circumstances. Proceed with the staking and tying of specimen hard-wooded plants, such as *Boronias*, *Croweas*, &c. Keep Heaths in the freest ventilated portion of conservatories, water them moderately. Remove plants of *Solanum Capsicastrum* when the berries begin to drop or shrivel, and save a few of the best for seed. Remove all damping or decaying leaves, and use every means at command for keeping down insects.

**Bedding Plants.**—Frames heated with hot-water pipes have been found unusually serviceable for these this season. The finer sorts of tricolor, bicolor, and other *Pelargoniums* of that description should be placed at once in an increased temperature, if not already done, in order to induce them to furnish cuttings. If these are struck early, good plants may be obtained before May. Strike

also some *Lobelia* and *Gazania* cuttings. Sow some *Lobelia* seeds in a hot-bed or warm pit. Start into growth *Verbenas*, *Coleuses*, *Iresines*, *Alternantheras*, *Lantanas*, *Cupheas*, *Abutilons*, *Solanums*, such as *marginalatum* and *robustum*, *Ferdinandas*, *Melianthus*, *Wigandias*, &c. for cuttings. Loosen the surface soil amongst *Calceolarias*, *Pyrethrums*, *Phloxes*, *Pansies*, &c., planted out in frames, and scatter some dry wood ashes amongst them.

**Hot-beds.**—Prepare materials at once for the construction of these. One made immediately of equal parts of stable litter and leaves will be found useful for starting a few early *Gloxinias*, *Caladiums*, *Achimenes*, and roots of *Lilium auratum*; also for cuttings of different kinds; and it will afterwards be useful for the raising of various kinds of seeds. Throw into a heap a mixture of two or three parts of leaves and one of litter, for another bed in February. Besides hot-beds necessary for bringing plants into flower, several are required for vegetable forcing, especially where there are few hot-water heated structures. In April and the two following months these beds will be useful for soft-wooded greenhouse plants, such as *Balsams*, *Cockscombs*, some annuals, and various odds and ends. In others, *Cucumbers*, *Chilies*, &c., may be grown; and those not required can be removed and used for manure, or turned for forming a compost for the potting bench.

**Indoor Fruit and Forcing Department.**—If the weather be fine, push down the lights of Pine pits about a fourth of an inch for two or three hours at midday. Cover frames containing Pines with mats at night. To such as are planted out in frames give no water if the heat is kept up by means of fermenting material. Watch carefully fire-heated pits or houses. For Vines coming into flower, maintain a night temperature of 65°. Admit a little fresh air as long throughout the day as is practicable when the blossoms have expanded, keeping up the temperature by means of fire-heat at the same time. If the air comes heated into the house by being made to travel along or over hot-water pipes, so much the better. Syringe Vines breaking into leaf, and if possible maintain the desired amount of heat by fermenting material. Remove loose bark from late Vine rods, and wash and paint them with some insect-destroying mixture. Syringe daily Peach trees whose fruit has set. Ventilate a little day and night houses in which plants are in flower, and give fire-heat at the same time. Prune the latest trees, and shut up another house for succession. If French Beans are not already in Vineries or pits, place them along the narrow front shelf in Pinerics. Place a few sprays of birch twigs in each pot, and run a cord along next the path, so as to prevent the twigs or plants coming in contact with the clothes of the workmen. Syringe them frequently and water them abundantly. Sow Mustard and Cress in boxes according to demand, and keep the boxes in early Vineries or Peach houses. Introduce also some roots of Mint and Tarragon. Keep up a succession of Rhubarb, Seakale, Endive, Chicory, and Dandelion, in the Mushroom house, or in any other place where a temperature of 55° can be maintained. If Seakale be forced too slowly it becomes stringy. Asparagus is best forced in hot-beds. If a large quantity of roots has been lifted at once, lay them in a heap but not so thickly as to cause fermentation, and cover them over with a mat. It is better, however, to lay them into the soil quite thickly, and to lift as required. Construct hot-beds for Potatoes. Start the tubers in some of the forcing houses, and after they have pushed into growth an inch or two in length, plant them out in the frames. Sow some Radish seed over the soil, the young Radishes from which will be ready for use before they become an obstruction to the Potato crop. Prepare hot-beds consisting of two parts of leaves, and one of litter for Turnips, Cauliflowers, Lettuces, Celery, Onions, &c. Brisk hot-beds are also necessary for Tomatoes, Melons, Cucumbers, &c.

**Fruit and Kitchen Garden Department.**—Uncertain weather makes uncertain work. Sometimes a day unseasonably fine is preceded and succeeded by deluges of rain, rendering it difficult to determine what to do first, or what can be done. In the mornings, if dry, wheel manure on to empty quarters. Trench or dig in the early part of the day, and when warm, nailing, pruning, and similar work should be proceeded with. In dry weather sow some white silver-skinned Onions on a warm border. Sow also a small bed of Radishes, covering with litter, and protecting the seed, after it begins to grow, from birds, with netting. After drawing earth to early Peas, sow some Round Spinach between the rows. Sow some early Dutch Turnip seed on a warm border, and treat it like Radish. Plant pretty deeply some early Potatoes in a warm border, the soil of which is dry and light. Plant, likewise, some tubers of Jerusalem Artichokes in any out-of-the-way corner. Sow some seeds of Vaneck Cabbage on a warm border. Make a second sowing of Beans, and, if necessary, another one of Peas. Pay attention to all plants requiring protection from frost, and have sheds cleaned out and in readiness to receive Cauliflower, Broccoli, Cardoons, &c. Have also a good store

of dry litter at hand for protecting Celery, Parsley, Spinach, Onions, &c.; such precautions may turn out to be unnecessary, but prevention is better than cure, and if the litter in question is not required for protecting vegetables out of doors, it will come in handy for covering hot-bed frames a few weeks hence. Obtain and prepare a fresh supply of Pea and other stakes. Re-point and otherwise render usable the old ones. Should espalier trees require new stakes furnish them at once, and re-point the old ones, which will make useful supports for young trees.

#### NURSERIES.

Pot on Bouvardias, Dracenas, Dieffenbachias, &c. Divide and pot singly choice Marantas, and keep them for a time in a frame inside the propagating pit. Increase the stock of any plants that are scarce. Pot off singly seedling Palms from seed boxes. Have stocks of Camellias, Orango trees, Azaleas, Gardenias, and Rhododendrons in readiness for grafting on in February and March. Young plants of *Cyanophyllum magnificum*, *Ficuses*, *Medinillas*, &c., must not be permitted to become pot-bound, otherwise they sustain a check; on the contrary they must be potted when they require it, supplied liberally with water, and, if practicable, have the advantage of a good bottom heat. Under this treatment good plants are soon made, and the growth formed before the end of the summer, and have time to become well ripened before next winter. Plants to be used for table decoration should, if their nature permits of it, have a strong loamy soil in preference to a peaty or spongy one, as firm soil is productive of stiff and hardy growth, not so liable to injury as that made in more open compost. Soft-wooded plants, intended for increase of stock, place in a damp, warm house or pit; Pelargoniums may be safely arranged along paths, where increased moisture and heat soon cause the production of young wood. Sow and prick off Ferns as convenient. Keep Orchids comparatively dry; but to such as are growing—as, for instance, the *Pleione*s—give a good share of water. If stock be required at once, divide *Odontoglossums*, *Miltonias*, &c. If these have commenced to grow, give them a little water. Imported *Cattleyas*, *Laelias*, &c., pot amongst broken crocks and a few pieces of charcoal; pot roots of *Sobralias* in loam, leaf-mould, sphagnum, and charcoal; and attach *Vandas*, and similar growing plants, to blocks with their heads downwards, so that water from the syringe may not find lodgement at the base of the leaves. Protect flower spikes and young roots from cock-roaches by means of wadding placed around the stems near the base, and poison or trap them as recommended last week. Trap wire-worms with pieces of Potatoes and woodlice in little pots containing dry moss; examine them every morning, and transfer the contents to a pot of boiling water.

**Outdoor Department.**—From pieces of ground not entirely empty lift the remaining plants, and lay them in some out-of-the-way corner. Manure and deeply dig or trench the ground and replant any plants not to be disposed of this season. Stocks for fruit trees should all be transplanted into plots according to their kind. Small and very young plants should be transplanted as soon as possible. Head back some stocks for grafting on. Protect Vines in pots by setting the pots as thickly together as possible and covering them over with a mulching of leaves or litter. Transplant young Conifers and plants with wide-spreading roots like the Elm. Four-year-old forest trees are the most saleable as well as the most suitable for permanent planting.

#### MARKET GARDENS.

If not already done, lose no time in sowing the third Radish crop. Ground from which Celery, Coleworts, or Savoys have been removed will suit it. Manure and deeply dig before sowing, so that the same operation will be unnecessary for the succeeding crops of this season. The earliest sown plantation requires no more protection from birds; only replace the covering in the event of frost. Remove into the alleys between the beds, every fine morning, the litter covering the second plantation, so that the plants may gather strength, become green, and also that the surface soil may get dried as well as the litter covering it. Use a long-toothed wooden rake for removing the litter and a steel-pronged pitchfork for replacing it. Rhubarb is beginning to grow a little naturally, therefore finish digging between the rows, and cover the crowns in open plantations with litter as soon as practicable. Under trees there is less danger of the crowns being injured by frost; therefore leave them to the last. It is impossible to wheel or cart manure on to the plantations with impunity; therefore get some of the workmen to fill big baskets with the litter, and others to carry them on their heads to the place where the litter is wanted to cover the crowns. The trampling of the men is much less injurious than wheeling on newly-dug ground, and it would be bad practice to cover the crowns before digging the ground. Although for forcing, the roots must necessarily be mutilated, in permanent plantations they should be very carefully preserved. Before digging the ground lately occupied by Seakale, let some women go over it and pick up every bit of root left, otherwise they

will grow and cause annoyance. Cut up the best pieces into finger lengths, lay them quite thickly together on a raised bed, and cover them over with an inch or two of soil. Leave them there until March, then dibble them in lines amongst Cabbages, so that they may occupy the ground after the Cabbage or Cauliflower and a Lettuce crop have been obtained. Burn or destroy by means of lime the useless roots. Uncover during every dry hour throughout the day frames containing Lettuces. Thin and keep clean the crop. Thin to a greater extent than ordinary if Carrots are growing along with them. Replace the sashes over the frames at night, and also in the event of rain during the day, but keep them tilted up a little unless frost is expected. Dust a little lime over and amongst Cauliflower plants growing under handlights, and keep the latter tilted up. Fully expose the plants in frames, for a too hardy constitution cannot be maintained; therefore thin them out a little and plant the thinnings under handlights or half-bushel vegetable baskets. If baskets be used, keep the edges covered with soil for a few days until the plants begin to revive. Cauliflower plants, as a rule, have already made too much progress, an evil that would soon become visible in the event of frost. Keep mats over Mushroom ridges, to ward off rains, and fix them on both sides by means of pegs. In gathering the produce expose the ridges for as short a time as possible. Fill up the alleys between the second lot of Seakale beds to be forced with fermenting manure, mulch the surface of the beds a little, erect hoop frames over them, place mats thereon, and then a covering of rank litter over the whole. Heat is thus soon communicated and growth induced. Force Rhubarb in a similar manner and also Asparagus, with the exception that the latter must be covered with a few inches of soil, and have a brisk bottom heat afforded it by means of a 3 feet sunk hotbed. Manure and dig every empty space. Level before digging all uneven surfaces, such as recently emptied Celery and Asparagus plantations. Weed Onions on dry days, and transplant if necessary. Use the hoe amongst Parsley, Cabbages, Lettuces, and Endive on fine days. Collect and burn prunings and other rubbish. Transplant suckers and lay in cuttings of fruit bushes. Head down trees for grafting on and cut back branches in furtherance of the same operation.

#### NEW THAMES BATHS.

MANY will be pleased to learn that the question of public baths is about to be taken up in earnest. We understand that a scheme for the building of several baths in various parts of the Thames is already under the consideration of the Common Council of the city. The proposal contemplates the eventual establishment of seven bathing places, to be situated at Woolwich, Greenwich, Ratcliff, Hungerford Bridge, Chelsea, and Hammersmith; and thus to place the means of bathing within reach of the whole population. At present, only a beginning is to be made, by the erection of a bath in front of the large pier on the Surrey side of the Charing Cross railway-bridge. The plan suggested to the Corporation is that of a large pontoon, floating a large iron reservoir, with a solid bottom, and not open to the flow of the stream. It is, in fact, to be a huge iron bath, with considerable depth at one end and shallow at the other, supplied with water from the river, immersed in the stream, but practically as distinct from the tidal flow as though it were erected far away from the Thames. The water which flows into it is to pass through a filter to be arranged in the pontoon, capable of purifying about a million gallons a day. The bath proposed is 150 feet long, and 35 feet wide; is to hold about 200,000 gallons of water; and will thus allow about 50 feet of space, and nearly 2,000 gallons of water to each of the 105 persons who will be admitted at the same time. There is to be a constant change of the water, as about five times the contents of the bath are to be passed through it every day; and it is even proposed to add a small heating apparatus, of sufficient power to keep the whole of the water at the permanent temperature of about 72°. The superstructure of the bath is to contain complete accommodation for 150 persons, and some forty private baths; and though the surface is to be covered in with a roof of glass and iron, which will completely shelter it from the weather, there will be provision for ample ventilation. Let us hope that the opportunities our parks offer for forming public bathing places will be taken advantage of at no distant day, and that the offensive spectacle on the banks of the Serpentine will soon be a thing of the past.

**Ink for Zinc Labels.**—Take of verdigris and sal ammoniac each two drachms, lampblack one drachm, water four ounces, to be well mixed in a mortar, adding the water gradually. It must be kept in a glass-stoppered vial. Write on the zinc with the ink, after shaking it well, with a quill pen; and after it is dry you may expose it to the weather or bury it in the ground for years, and it will be as legible as when first written.

## THE GARDEN.

—o—o—o—  
 "This is an art  
 Which does mend nature: change it rather: but  
 THE ART ITSELF IS NATURE."—*Shakespeare.*  
 —o—o—o—

### THE FLOWER SHOWS OF 1873.

THESE, in a short time, will begin to attract attention, and to give new opportunity to our gardeners to display the results of their skill and enterprise. The dates of many have already been advertised, and no doubt many a beautiful object is already undergoing some kind of preliminary preparation, with a view to its competing for honours. Early in the season as it is, perhaps one or two ideas with regard to the first principles of flower shows may not be premature. There will be so much the more time for those who are interested in the matter to think them over, and apply them, if they think proper, when the occasion arrives. The first we would name is that if the great flower shows of England are to be chiefly valued for their direct purposes, and on account of their intrinsic merits, instead of as giving special opportunities for enjoyments of a social character—in their way perfectly legitimate, no doubt, but still only accessory to the original design—the people in general must have a direct and personal interest in them. The private gentleman whose garden is known only to himself and to his immediate friends, the lady who tends her greenhouse with her own hands, watching her plants day by day as if they were children, must be made quite as welcome as the magnates. By a judicious and catholic system of prizes, every simple admirer and cultivator of flowers for "their own sweet sake" should have access to the pleasant tournament, and get their full share, as far as merited, of rewards and gratulation. When people know that honours and kindly words await success in any *bona fide* effort to promote floriculture, no matter how simple, so that the world is the better for it, there is a wonderful impetus given to endeavours; and it is perfectly certain that this principle only wants enlarged application in regard to our great flower shows for them at once to become a part of the life of the nation, and one of the best signs and certificates of its progress in good taste and good feeling. The main idea of the flower show is, of course, to encourage popular taste for good flowers and to stimulate enquiry and zeal as to the best mode of producing them; and when this idea is carried out effectively, a noble moral end is served, as well as the proper and honourable one of self-interest. To give abundant realization to it, we conceive that all schedules of prizes should give plenty of chance to the exhibitors of "miscellaneous plants," and of "single specimens" of old-fashioned, it may be, but still lovely things that it is pure nonsense to talk of as having gone "out of fashion." If this be true, then it is high time they came into fashion again, and were allowed to occupy their proper places. The simplest thing, well grown, with plenty of thought and heart put into its culture, is every bit as creditable, and as deserving a place in the flower-show, as the newest *Dracæna* or *Caladium*. Half a dozen times at least have we known some dear old rejected plant of the modern school brought out in such exquisite form as to be taken for some wonderful importation from the antipodes. While the old-fashioned things and those which may perhaps be contemptuously called by some persons, "everybody's flowers," should thus be let have their fair share of standing room, there should be encouragement given likewise to artistic groups. What if they do happen to be constituted sometimes of the familiar and the inexpensive? So much the better, for if a man loses his aptitude for seeing beauty in what is simple and familiar, depend upon it just in that degree he impairs his aptitude for discerning it in the rare and costly. A flower-show that brings fifty people into the arena, and thus causes the race to be so much the more "neck and neck," will always do incomparably more good to floriculture as a national love and a national pastime—and pride too, for that matter—than one that is left in the hands of some half dozen, to compete with whom is impossible. This good end, we repeat, is ensured by a

judicious and liberal encouragement of the single specimen growers, and the admirers of flowers that were the delight of accomplished minds before ever sensationalism was invented, either indoors or out of doors. It is true that this class of exhibitors has never been forbidden to come forward; but have they ever received straightforward and liberal encouragement to do so?

Secondly, we hope to see our exhibitors striving this year more to produce that grand and sweet general effect, that charming *coup d'œil* which contributes so profoundly to the usefulness of the flower show. Nice plants are often lost through being ill-placed, or with contrasts that fail to bring out their peculiar features of excellence. There should always be a sense of good *vis-à-vis*, and always a secret impression of the picturesque, or what have we learned from marshalling our plants in the garden borders? Depend upon it, the first principles are just the same that rule the true arrangement of the flowers and shrubs in a good garden, the leaves and corollas in a bouquet worthy the name, and the plants that are intended to make the Show. To say that there is not "time" for this will not do. Say rather that the manipulator has not brought sufficient taste and knowledge to his task. Good general effect likewise demands that the individual plants should none of them be in a state of unhappy constraint. If you want to spoil the really picturesque and permanently instructive and valuable part of the flower show, by all means dress up the plants in such a way as to bring every bit of colour to the front, swamping and abolishing the green, and whenever convenient enable the visitor to see the scaffolding within, and be reminded of those structures of old which went by the name of "whited sepulchres." Nature always intended that her plants, like our honest men, should be seen "through and through"; any one who accustoms himself to admire mockery in plants, may not unreasonably be suspected of inaccuracy in more important things. Nature, spontaneously, never deals with her produce as it has been the practice, now happily becoming subdued, and tending, we hope, to extinction, to deal with the *Azalea* when said to be "faced." Those specimens of the gardening art will always be the most permanently pleasing in which a due balance and proportion of leaf and blossom is preserved, and a certain elegant freedom permitted to every part. Rampant-growing and over-luxuriant plants of course must be made becoming, and the most is to be made of a plant's wealth of purpose and fecundity; but that is a very different thing from constraining the expenditure of force all to one side, or after some arbitrary fashion. Far away prettier than were ever any of those gigantic cones, sugar loaves, and fans, one all crimson, another all white, as if they had been dipped in a dyer's vat, and were now put in the Show to get dry, are those little imitative trees made by training, so as to have a single stem, *Palu* tree fashion, and a graceful head of branchlets, foliage, and flowers, the same whichever way you look. It may not be quite right to make one plant simulate the outlines of another, but it is unspeakably better to do so than to make them caricatures of "geometrical solids" or peacock's tails. The public, who are generally very good judges in matters of common sense, though not, perhaps, in the merits of individual plants, never really relished it; and we feel assured that when the unbiassed forms of nature are made the rule and leading features of flower shows, the public will award them a far more cordial amount of approval.

Thirdly, and lastly, we hope that every succeeding year there will be more and more encouragement given to displays of the produce of the kitchen garden and the fruit garden. Beauty, it is true, is a larger fact than so-called "utility." That was a sound doctrine, however, of the old philosophers when they made their "kalon" or the perfectness of beauty, to consist in the combination with the lovely to look at, of that which is economically serviceable. A gardener is never better employed than when he is striving to improve the size and quality of his Grapes and Lettuces. Wise men want prose as well as poetry; substantial for the dinner-table as well as beauty for the boudoir and the conservatory. We hope accordingly that a side-table, or better still, a lateral tent for fruits and vegetables, may always be made a proviso and a feature of every show.

## NOTES OF THE WEEK.

— LORD STAMFORD sends us from Enville Hall a twig of Horse Chestnut bearing young green and fairly developed leaves. The whole tree has opened into leaf in the same manner. After this the celebrated tree of the "Twentieth March" ceases to be so remarkable.

— OUR table is now graced by a pot of the beautiful and true smaller Daffodil (*Narcissus minor*) in perfect bloom, sent by Mr. Ware, of Tottenham. In addition to its great merits as a rock and border flower, this, from its distinctness from the ordinary type of Daffodil grown in greenhouses, is well worthy of pot culture, for the sake of a very early bloom in winter.

— MR. COLE, after fifty years' public service, has announced his intention of resigning his post in connection with the Science and Art Department. It would be difficult indeed to estimate the extent and value of the services performed by Mr. Cole in behalf of science. Some of our provincial botanic gardens, such as that at Dublin, are now under the control of his department.

— WE have received Mr. David Thomson's "Handbook of Fruit Culture under Glass" (Blackwood), a book which will be welcome to many. If we mistake not, a good deal of the matter of the book was originally published in the pages of the *Gardener*, which, however, does not impair its usefulness. We hope to notice the book more fully at an early date.

— A REPORT has been made by the Parks and Open Spaces Committee of the Metropolitan Board, stating that Messrs. Hooper, of Covent Garden, had presented 950 Irises, and that Messrs. Barr & Sugden had furnished 1,625 bulbs for planting in the ornamental grounds of the Victoria Embankment.

— NINE hundred and eleven tons of Broccoli, the growth of West Cornwall, have been conveyed by rail to London and elsewhere over the Cornwall line in about six weeks to the 12th inst. In the corresponding period of last year the quantity amounted to no more than 168 tons. The absence of frost may be assigned as the reason for the increased successful produce, so advantageous to the cultivators and beneficial to the railways.

— IN the Orchid-houses of Mr. Day, of Tottenham, are some excellent specimens of that favourite tribe of plants now in full beauty. Amongst these are *Oncidium ornithorychum*, laden with flowers, and amongst the plants of this *Oncid*, besides the rose-coloured flowered ones, there are others that bear pure white blooms. On *O. pulchellum* there are fifty flower-spikes; *Acridis giganteum* is bearing two large flower-spikes; and *Epidendrum macrochilum* is also excellently well flowered. Besides these there is, amongst many Phalenopsis, a plant of *P. Schilleriana*—a fine broad-sepalled variety, with upwards of seven dozen flowers; *Cypripedium Reichenbachii*, a pretty species; and various kinds of *Masdevallias*, including *Tovarrensia*, *ignea*, and *Veitchiana*, flowering freely.

— IN carrying out alterations on the Columbia Market estate, purchased by Baroness Burdett Coutts for the purpose of making public improvements in the neighbourhood, the Baroness cleared a triangular piece of land at the corner of Crab Tree Row and Hackney Road, on which stood a number of dilapidated houses, and formed the area into an open space for the benefit of the tenants of the Improved Industrial Dwellings, and other buildings in the locality. The Baroness is now about to plant this open space with trees, and also to place circular seats around them for the twofold purpose of protecting the trees, and also to be of use to the public in fine weather. In addition to the trees and the seats a number of "rests," similar to those in Piccadilly, are also to be erected, after which it is the intention of the Baroness to have the land legally made over to the Bethnal Green vestry, so that the same may be preserved as a free and open space for ever for the benefit of the inhabitants.

— AN interesting account is given by the *New York Sun* of the Ramie Plant, or Chinese Grass. Considerable attention is now being given by the planters in some parts of the South to the cultivation of this plant, which grows well in Florida, Georgia, South Carolina, and, in fact, almost anywhere from latitude 33 southward to the Gulf of Mexico. In Louisiana some of the planters are replacing the Sugar-cane with Ramie, which does not require replanting, demands comparatively little labour in cultivation, and entails no great expense for machinery to prepare it for market. So far as known, it has no insect enemies, its fibre is less bulky and more easily transported than cotton, and it is sure of a ready sale, at remunerative prices. At present the fibre sells in England for 240 dols. per ton of 2,000 lbs., or 8½ cents. per lb. The fibre, which forms its commercial product, is the inner bark of the stem, and when exposed to view by separation from the husk, presents a brilliant pearl-white lustre. This fibre is longer and more uniform than any other except silk; it is stronger and more elastic than either hemp or flax; takes colour

as well as a good quality of silk; and when properly prepared from the raw material, may be spun into fine yarns, suitable for mixing with wool in the manufacture of Delaines, worsteds, and other light fabrics. Without admixture it can be woven into fabrics which, it is said, will surpass the finest linens in beauty, strength, and durability.

— SOME of the large-leaved or *Megasea* section of the Saxifrage family are now coming into flower about London. For these plants this is remarkably early.

— DURING the month of November there were 9,529 barrels of Apples sent over the Wilton (New Hampshire) Railroad, destined for England.

— THE Microscopic Society have determined on giving a *soirée* at the approaching Royal Horticultural Society's Exhibition at Bath, devoted, as far as possible, to horticultural subjects.

— THE cold at Chicago and in the Lake districts generally is so severe that it is feared the fruit trees in that quarter will be destroyed.

— A PUBLIC and gratuitous class for instruction in fruit culture and market gardening is held twice each week in the salons of the scientific societies in Paris.

— MR. WARE has sent us some specimens of the interesting *Narcissus papyraceus*, now, and for some time past, in flower in his nursery at Tottenham. This is a good addition to very early spring plants, the flowers being pure white and delicately scented.

— MR. BARR writes to us as follows.—"On the 20th inst. I had in bloom, in my trial ground at Tooting, *Cyclamen Atkinsi*, pure white blotched with crimson; *Cyclamen coum album*, bluish white, blotched with crimson; *Cyclamen coum vernum*, rich magenta; *Scilla bifolia*, clear blue; *Scilla sibirica*, intense blue; a stray bloom of *Triteleia uniflora*, with its white beautifully porcelain-shaded flower; *Narcissus papyraceus*, white; *Bulbocodium vernum*, with its beautiful rich lilac naked flowers; *Crocus Aucheri*, golden yellow; *Crocus variegatus*, white and purple, and *Crocus reticulatus*. 'I never,' he adds, 'observed the beauty of this *Crocus* so strikingly before this season; the brown-black band with the golden margin are most beautiful when the flower is closed, as is also the mass of golden-yellow when the flower is open; *Crocus biflorus*, with its black striped petals, concludes my list of bulbs in flower at present.'

— MR. A. W. DILLARD, in the *Mobile Register*, endeavours to account for the generally acknowledged increase in the severity of the winters in Alabama. In all European countries it is commonly believed the climate has become warmer in proportion as the forests have been felled and the land cultivated. In Alabama, however, similar operations have apparently produced opposite results. The writer, however, believes that the general dryness of Africa, and especially of the Great Desert, has no inconsiderable effect on the climate of Europe, and accounts for the great difference of temperature between the same latitudes in Europe and America. He accounts for the change of climate in Alabama and other southern American States in the following way:—"The felling of our Southern forests gives a more unrestricted scope to the north-western winds, chilled by the snow on the Rocky Mountains and the ice of the northern lakes and rivers. These bleak winds are not counteracted by warm gales, blowing from a dry country, such as Africa; consequently they exert all their chilling influence on our climate. The gales which we have from the south are impregnated with a good degree of moisture, and so add to the cold consequent upon the blowing of the wind from the north."

— THE following is an abstract of the Custom-house regulations to be observed in respect of goods sent from foreign countries to the Vienna Universal Exhibition. The frontier Custom-houses will direct goods (without opening the packing-cases and parcels) to the chief Custom-house in the exhibition. Detailed list of contents of packing-cases must accompany each consignment. The chief Custom-house office examines goods, and books the detailed lists. Foreign commissions must keep an account of the goods received. Detailed list of contents has only to specify goods according to commercial denomination as to kind and quantity. No goods will be allowed to be taken away without a permit. Goods going back will be directed by the chief Custom-house to the respective frontier Custom-houses. Goods remaining in Austria or Hungary are liable to import duty. Goods, owners, and commissions, are responsible for the amount. Agents taking charge of goods incur the same responsibility. Discrepancies between the contents of packages and the detailed list, and the unauthorised removal and sale of goods, will be dealt with according to law. Tobacco and goods manufactured thereof are not permitted to be sold in the exhibition, nor to be brought away for such purpose. Goods not entered for exportation three months after the close of the exhibition are liable to import duty.

## GARDEN DESTROYERS.

### BARK-BORING BEETLES.

(*TOMICUS (BOSTRICHUS) TYPOGRAPHUS*.)

THE bark-boring beetle whose workings are figured in the accompanying woodcut is known by the name of *Tomicus typographus*. The beetle itself is figured in the left hand corner much magnified, and individuals of the size of nature are represented in the workings. It is brown in colour, and the larva is white, with a yellowish head and a brown mouth, and has neither feet nor eyes. It lives under the bark of Pines and Firs, and is reputed to do them much damage. A passage from Wilhelm's "Recreations of Natural History," quoted by Kirby and Spence ascribes to this insect the destruction of millions of trees in various parts of Germany. We are very sceptical on the point, and are there-

forests. It reappeared in 1757, redoubled its injuries in 1769, and arrived at its height in 1783, when the number of trees destroyed by it, in the above forests alone, was calculated to amount to a million and a half, and the inhabitants were threatened with a total suspension of the working of their mines, and consequently with ruin. At this period, these insects, when arrived in the perfect state, migrated in swarms like bees into Swabia and Franconia. At length, between the years 1784 and 1789, in consequence of a succession of cold and moist seasons, the numbers of this scourge were sensibly diminished. It appeared again in 1790, and so late as 1796 there was great reason to fear for the few Fir trees that were left."

This is very circumstantial, and we do not at all doubt that the statements as to the destruction of trees, &c., are quite accurate; but we wholly repudiate the idea of giving any weight to the opinions formed of the cause of the mischief, unless

*Tomicus typographus*.

fore bound to reproduce the authority against our view:—"The insect in its preparatory state feeds upon the soft inner bark; but it attacks that important part in such vast numbers (80,000 being sometimes found in a single tree) that it is infinitely more noxious than any of those that bore into the wood, and such is its vitality that though the bark be battered, and the tree plunged into water, or laid upon ice or snow, it remains alive and unburt. The leaves of the trees infested by these insects first become yellow; the trees themselves die at the tops, and soon entirely perish. Their ravages have long been known in Germany under the name of wurm-trökniss (decay caused by worms); and, in the old liturgies of that country, the beetle itself is formally mentioned under its vulgar appellation, the 'Turk.' This pest was particularly prevalent, and caused incalculable mischief about the year 1665. In the beginning of the last century it again showed itself in the Hartz

where they are corroborated and supported by similar facts, observed in our own times. We know that a large part of the natural history of those older times is wholly untrustworthy, especially so far as regards the explanation of phenomena, and even although it had been otherwise we cannot be expected to give more weight to the opinions then formed than we would to opinions similarly formed now. And certainly now the coincidence of trees dying at the time they were attacked by *Tomici* would never be accepted as proof of the latter being the cause of the former without much and careful examination into every collateral circumstance, and a search for any other cause to which it might possibly be ascribed. We therefore do not feel called upon at all to examine or attempt to account for the facts above quoted, or many similar ones which might be quoted. We claim to be entitled to set them aside, and to be guided solely by facts occurring in

our own time which have been subjected to the scrutiny of modern science, and regarded by that light no warrant is to be found for attributing to this insect the power of inflicting any serious damage. In fact its purpose and its powers are similar to those of the *Scolytus destructor*, viz., to prepare for the removal of decaying or moribund trees, but also with power, under special circumstances, to do a certain amount of mischief, which, however, cannot be carried far, as the exercise of that power, improperly applied, that is, applied to the injury of sound trees, brings with it the creature's own destruction. The resemblance between this species and the *Scolytidae*, both in their habits and in the form of their burrows, has struck older authors; and it is curious to find that resemblance adduced by them to support the then opinion of destructiveness of the *Tomici*, just as we adduce it now as an argument to the contrary. Loudon ("Arboretum," iv. 2, 143) says, "Its proceedings are also very similar to those of the *Scolytus* (to which genus, indeed, it is very nearly allied); so that it would be as erroneous to attribute the destruction of the German forests to other primary causes, and to consider the *Tomicius typographus* as a secondary cause, as it is to deny that the *Scolyti* are the cause of the destruction of the Elms around London." As that is now very generally denied, we must, upon Loudon's own showing, be entitled to regard the *Tomicius* from the same point of view. We believe that it may sometimes attack sound trees when it is present in numbers and cannot find trees suited to its wants (that is, feeble and weak trees with the flow of sap languid or almost absent); but when it does so, the mischief checks itself; the flow of sap in the sound trees is too abundant and drowns the *Tomici* that have ventured to open its floodgates. A. M.

**Slug Caterpillar of the Pear.**—I send you the life-history of the little Pear pest (*Selandria aethiops*), which I have extracted from my note-book. In April last, about the 15th, four of these little sawflies came from their cocoons. The larva had been noticed to be very destructive to the young Pear trees at York during the previous summer, feeding on the epidermis of the leaves, and exposing to view the network of the veins. Whole branches were thus disfigured. The eggs, as in the case of the Gooseberry sawfly, would seem to be laid along the mid-rib of the leaves. The larva is blackish and slimy, something after the manner of the *Cionus* larva, but more attenuated and leech-like. It is a voracious feeder, like most of its tribe, and at each moult the skin may be seen adhering to the leaf or hanging loosely to the edge. The transformation is subterraneous. The cocoon is brownish, and slightly larger than that of the Gooseberry sawfly, whose habits of life are so admirably described in the letters of "Rusticus." The perfect insect is black, with the four front legs hyaline. The saw apparatus is very visible. It is more stunted in form than the Gooseberry sawfly.—*Peter Luchbold (Horticult. Loan Lodge, near York) in the Field.*

**Phylloxera Quercus.**—The recent account of *Phylloxera vitifoliae* or *Vastratrix*, in the *American Naturalist*, mentions that it is oviparous in summer, and hybernates in winter, and that there are no eggs then. In this it agrees with *Phylloxera Quercus*, which I have often observed, for more than twenty years, to lay eggs in summer and autumn, which eggs are shortly hatched, and their occupants do not lay eggs, but pass away in early winter, except a remnant, which must serve for the continuance of the race. As the moving power of the creature is very little, it cannot go far from the leaf, to whose recesses it must resort in the spring; and the means whereby it shelters itself from severe frost have not been observed. Other families of aphides pass the winter in the egg-state; and *Chaetophorus aceris* is remarkable on account of its aestivation, or passing the summer in a suspension of growth, as is the case with some caterpillars; this occurs in a very early stage of its existence. *P. Quercus* is represented, beyond the Atlantic, by another *Phylloxera* (*P. Rileyi*, of Lichtenstein), which frequents Oaks in North America.—*Francis Walker, in Newman's Entomologist.*

**Osier-bark Steep a Cure for Ants.**—Mons. Colin Lebert, of Blois, has found that water in which the bark and parings of the Osier have been soaked, will remove ants. On one occasion, he says, perceiving a young tree which was infested with ants, I sprinkled it with the Osier steep, and to my surprise the ants fell off as if immediately dead. The result so struck me that I determined to again try the effect on a nest; this time I was sure of the instantaneous effect, and I concluded this water was certain death to them. I have also proved that it is in no way injurious to the plants; on the contrary, when once freed from ants, they thrive with greater vigour than before. The Osier steep forms, therefore, a simple and effective means of getting rid of these little depredators.

## THE INDOOR GARDEN.

### COOL ORCHID HOUSES.

A FEW words concerning these may be of service to those who are about to begin to grow cool Orchids, and have no special convenience for doing so. In the first place, no very elaborate or expensive structure is required, and no costly heating apparatus is requisite beyond the amount of hot-water pipe necessary to exclude frost from a common greenhouse; there will, therefore, be a saving in fuel and labour, compared with the expenses attending the culture of Orchids which can only be grown successfully in a close humid stove. For the culture of *Odontoglossa*, *Masdevallias*, *Disas*, &c., I would recommend a small span-roofed or lean-to house; either will do, though a span-roofed one is, perhaps, the more convenient of the two, if a suitable site can be obtained. If a span-roofed house is decided upon, do not build it too large, say, 12 feet wide and 8 feet high. This will be quite large enough to commence with, and will be more likely to give satisfaction than would a larger structure; the side walls should be 9 inches thick, and about 5 feet or 5 feet 6 inches above the ground level, leaving spaces for ventilation, as shown in one of the annexed sections, which is a representation of the cool Orchid house at Fernhurst. Top ventilation should also be amply provided for by a longitudinal flap (as shown in the illustrations), which can easily be raised from the inside. The ventilators in the side walls may be closed by means of wooden slides outside. A house of this description of the simplest construction, heated efficiently, as shown, by a flow and return 4-inch pipe on each side, may be erected at very little cost. It can be constructed of any length; one from 60 feet to 70 feet would be large enough for a good-sized collection, and this length might very advantageously be divided in the middle by a glass partition and door, so as to allow of one compartment being kept rather warmer or drier than the other, as might be required. The staging or side benches will be about 4 feet wide and about 4 feet high, or one compartment might have the benches 3 feet high, so as to give more head room to larger plants. These benches should be either stone or slate slabs placed upon cast-iron supports. Iron is better than wood, which will naturally decay quickly in a humid atmosphere, and might give way suddenly, causing sad damage. This really happened in the case of a celebrated collection near Manchester not long ago, and did very serious damage to some of the finest *Phalæ-nopsis* in this country. In the centre of the house a cistern may be constructed, into which all the rain-water from the roof might be conducted for use inside. As has been already explained, moisture is essential to the well-being of all Orchids, and as bare slate benches speedily become dry after having been watered or damped down, it is a good plan in practice to cover them with a thin layer of cannel coal, broken up small and carefully washed. In addition to this, the benches may also be made to hold water, which, during the hot summer months, will be highly conducive to the health and vigour of the plants. The space bordering on the path beneath the side benches may be planted with *Selaginella hortensis*, which will soon form a fresh green carpet and materially aid in giving a neat and clean finish to the house; or a few Ferns may be planted, as shown in the illustration. During the hot summer months the plants will require to be carefully protected from the sun's rays, and blinds or rollers should be provided for that purpose. In order to prevent cold draughts from injuring the plants, it is a good plan to cover the ventilators either with perforated sheets of zinc or else to tack pieces of coarse tiffany over the openings inside the house.

These and many more little details will, however, soon suggest themselves to the mind of the attentive cultivator, who must be ever ready to counteract any unhealthy symptoms which his plants may show through being subjected to a course of adverse circumstances. The construction of cool Orchid houses does not call for any great amount of skill; they may, therefore, be erected under the direction of any intelligent workman who may happen to be about the place, in a few weeks at most, and their first cost will be but

a trifle compared with the pleasure the culture of these lovely plants will afford.

Although some Orchids grow freely in a cool house or compartment which is kept at a mean winter temperature of 45°, still there are other species that require a temperature 8° or 10° warmer in order to grow them successfully. They would both thrive and bloom in the cooler house, but not with that luxuriant vigour which true lovers of Orchids delight to see. If a house, say 60 feet long, is built it should be divided in the middle; this gives two compartments of 30 feet each, and one of these may be kept warmer than the other by the addition of an extra row of pipes, one flow and return. In this warm end many *Cattleyas*, *Lælias*, *Trichopilias*, *Cypripediums*, and *Oncids* may be grown, which would hardly give satisfaction to a connoisseur if grown in the cool end along with the *Odontoglots*. Many of the Orchids usually grown in the East Indian house will bear with absolute impunity a mean winter temperature of 50°.

I have known Orchids cultivated with marked success in small houses partially sunk below the ground level. Plants as a rule grow well in such houses, but there may be very good arguments raised either for or against them. The atmosphere of such houses is generally humid and genial, and they do not require so much artificial heat as houses do which are more fully exposed; they are also very convenient in being easily protected from frost by throwing a few mats over them at night. On the other hand the ground has to be excavated before such a house can be erected, and such houses are not the most convenient for lady visitors to enter; still on the whole they answer remarkably well, not only for Orchids, but also for stove plants and Ferns. Orchids have been well grown at Syon house and at other places in these partially sunk houses. As has been previously remarked, Orchids are not so exclusive as to require a structure absolutely for themselves; indeed, I have seen some of the commoner free-flowering species beautifully grown in all manner of out-of-the-way places, both in England and Scotland. Orchids have also been grown in a Vinery very successfully by Robert Warner, Esq., of Broomfield, and others. The partial shade of the Vines and the moist genial atmosphere are highly conducive to the healthy vigour of many *Dendrobies*, *Lycastes*, *Anguloas*, and *Odontoglots*, and the crop of Grapes is a very agreeable secondary consideration. Mr. Warner has more than once advised the association of Orchids and Vines, and he moreover very truly asserts that "there are few Orchids worth growing which might not be cultivated under Vines." I know from experience that many choice *Dendrobies* make a vigorous growth in the genial heat of a warm vinery in which bright sunlight is subdued by the fresh green foliage above, and this is equally true of many other genera. The accompanying

sections of houses (see p. 67) will be found adapted to the culture of Orchids under different conditions, and similar houses may be erected at a very moderate outlay. F. W. B.

(To be continued.)

LUCULIA GRATISSIMA.

THOUGH one of the oldest of conservatory plants, this is rarely met with; and the wonder is that it is not a conspicuous object in every throughout autumn, winter, and spring, showy, ornamental, and gratefully fragrant, it is one of those plants that deserves all that can be said in its favour, as every one will acknowledge who has seen it in full beauty. It is considered rather difficult to propagate by cuttings. Perhaps it is so, compared with some things; but once the plant is rooted and established, it will grow as freely as a common Laurel if planted out in a bed. It will grow well under even adverse circumstances, as I can testify from experience, but will not flower freely, nor at all sometimes, if the winter temperature is often allowed to fall below 45° or 50°. I have had it in fine

Span Roofed Cool Orchid House, partly below ground.

bloom in a greenhouse during mild winters, after a favourable summer had matured the shoots well and early, and at one time I was under the impression that protection from frost was all that was required in winter to flower it successfully; but after a good many years' experience I find it requires to be grown in an ordinary greenhouse temperature with plenty of air and light during the summer, and kept warm enough in winter to promote the free expansion of the flowers. If it receives this treatment, it will abundantly repay the trouble. It associates well with *Camellias*, *Oranges*, *Acacias*, *Heliotropes*, *Heaths*, and such like. When *Camellias* are its companions a compromise might be made by keeping the night temperature at 40°, and allowing it to rise from 5° to 10° during the day. This would suit all such subjects well, and it is much better to select a few really good things that can be grown in a healthy way together than attempt to grow too many varieties where one house has probably to hold all. Though it is much better to begin with an established plant from the nursery, I may state that the *Luculia* is propagated by cuttings of the young shoots about May or June, or when the wood is just getting middling hard. They should be inserted in a mixture of sand and leaf-mould, least of the latter; have a gentle bottom heat, and be covered with a bell-glass,

Cool Orchid House at Fernhurst.

and shaded until they are rooted, when they should be potted off and grown on for a bit in a vinery until fairly established. After this the greenhouse is the place for them. One good plant will be enough in a moderate-sized house, and it should be planted out in a mixture of loam and peat, or leaf-mould and silver sand, though I have seen it growing vigorously in strong loam alone. In order to get the plant up to a good size as soon as possible, the shoots should not be cut back, but tied down, or in any way that is found most convenient to form the foundation of a good plant. In this way the shoots will break at every joint, and in a year or two a large plant will be the result. Once this is secured the

shoots should be cut in pretty closely every season after flowering, in order to keep a well furnished bush. The shoots grow about 18 inches or 2 feet every season, in an ordinary way, and each shoot is furnished with a flower truss at its extremity. During the summer the plant should have plenty of water at the root, and liquid manure frequently when the soil is well filled with roots. J. S.

PSILOTUM TRIQUETRUM (Swz.)

THE following remarks on the occurrence of this plant on decayed tubs in the Palm house at the Royal Botanic Gardens, Edinburgh, were made by Mr. James McNab at the meeting of the Edinburgh Botanical Society held on the 9th inst. :—

About twenty-five years ago, while visiting the gardens of Sir George Stannton at Leigh Park, in Hampshire, I was surprised to find the surface soil of several tubs in one of the large plant houses there covered with tufts of the *Psilotum triquetrum*, a Lycopodiaceous plant, native of the West Indies. The *Psilotum* is a dark evergreen perennial herbaceous plant, with triangular stems, but destitute of leaves, resembling in some respects the Bilberry (*Vaccinium Myrtillus*) in its winter condition. Mr. Alexander Scott, who was then gardener at Leigh Park, could give me no information how it got into the tubs, his first impression being that it was the Bilberry which had come up in the rough turf soil used for potting purposes. For the last ten or twelve years the *Psilotum* has been growing on the decayed portions of several tubs in the Palm house. It first showed itself on the sides of a tub in which a large Bamboo cane grew, and afterwards on a partially decayed one in which a large Banana was cultivated, but that had been previously used probably for a Palm or some other arborescent plant. It is now abundant on a tub 8 feet in circumference and 2½ feet deep, in which a plant of *Sabal Blackburniana* has been growing for the last ten years. Besides the tufts which grow from the sides, some also proceed from beneath. The tufts are pushing through the green paint on the outside, and the tared inside, as well as through the bottom, which has been tared both inside and outside. How the *Psilotum* got into these tubs is quite a mystery. If increased by spores none have been seen growing on the neighbouring tubs, although several are much decayed, nor am I aware of any pot plant of *Psilotum* ever standing in the Palm house.

The *Psilotum* is also growing on the surface of several pots standing in a detached plant pit. It was chiefly on pots in which seedling Bamboo canes were growing, where the roots had filled the pots, so that little room was left for soil. It is also growing close to the stem of a South American Euphorbiaceous plant (*Pedilanthus tithymaloides*). All the plants which come up naturally are 8 inches long, being dwarfer than the ordinary form of *Psilotum*, also finer in habit, with somewhat pendant tops, not unlike the *Psilotum dichotomum* of Willd. When taken from the tubs and cultivated in pots, it becomes stronger, resembling the true *P. triquetrum*, except in the points which still remain pendant. Our original plant of *P. triquetrum*, about 1 foot in height, stands in a separate plant pit, with a collection of Lycopods and Ferns, but shows no symptoms of increasing, as no young plants have ever been seen in any of the neighbouring pots.

NOTES AND QUESTIONS ON THE INDOOR GARDEN.

**Saccolabiums.**—At page 43 of your last issue, "F. W. B." says "There is a white variety of *Saccolabium*, called *Hoffordianum* by growers." This is doubtless a slip of the pen, for *Harrisonianum*, which is a white-flowered variety of *S. violaceum*, whilst *Hoffordianum* is the largest and most brilliant coloured form of *Sputatum*. Although I feel fully sure your correspondent is aware of this, the error should be corrected for the benefit of those of your readers not so well conversant with the facts.—G.

**Acacia Riceana.**—This is an extremely graceful *Acacia*, and is well worthy of extensive cultivation. Its long penulion shoots, covered with flowers their whole length, are exceedingly useful for decorative purposes. It may be trained either as a standard tree—which is its natural habit—or as a climber. I have a plant about twenty years of age, growing at present under rather adverse circumstances, with its roots outside, and trained up the rafters of a greenhouse, which is never fired except to exclude frost; yet it grows well and flowers during the winter most freely, but it never ripens its seed. For cutting for bouquets it is a fail-me-never. It should be in every collection of greenhouse shrubs.—J. S.

**The Orange as a Conservatory Plant.**—The Orange deserves to be included among winter and spring blooming plants, for the sake of its blossom, which, as everyone knows, is exceedingly well adapted for bouquets and decorative purposes. The Orange requires to be studied a little to keep it in good health. Plants in pots moved hither and thither are rarely to be seen in good condition, but are sickly specimens or the victims of scale. It is a plant that does not require a high temperature; but it likes a steady one. A good bush planted out and allowed a minimum temperature of 45°, root and branch, during the winter, and a greenhouse temperature in summer, will yield every spring a perfect load of blossoms; and its dark luxuriant foliage will be no harbour for scale, which I have seen disappear from a plant entirely after it was planted out and treated liberally. The common Orange, or vigorous-growing kinds, are, I think, the best for flowering purposes, and stand cutting as well.—J. S. W.

THE FLOWER GARDEN.

THE CARNATION AS A BORDER FLOWER.

OF all flowers for a button-hole, give me a sweet-scented clove Carnation or pretty edged Picotee. They have a long stem expressly suited for the purpose, a rounded form that is always neat and finished, and a variety of markings and colouring that renders continued sameness impossible. I am fortunate in having a large number of plants, both of Carnations and Picotees; and during the past summer, from the time the earliest Pink flowered down till this present time of writing, on the 4th of November, I have not at any time been without a flower of these dear old favourites. The reason is plain enough. A few years ago I commenced to raise Carnations and Picotees from seed. I had been supplied with a mixed packet of seed of a first-rate strain; but this was in the spring sown along with seed of other hardy perennials in the open ground. It came up quite quickly and grew well. In the following winter the plants were put out into a bed some ten inches apart, and I had next summer one of the most charming collections of these beautiful flowers I have ever seen thus roughly grown. From that time forth I have always annually sown a pinch of seed, to keep variety and plenty of stock. Seedling plants in the hands of amateur cultivators whose space is limited should in the winter be planted out into shrubby borders amidst other perennials, or in mixed beds, and with profit also in odd nooks and corners of the kitchen garden where vegetables cannot be cultivated. The amateur can find no pleasanter occupation than when engaged in the work of neatly supporting with a small stick and a piece of bast matting the stems that carry the flowers of his hope, not bundling them up in an ungainly mass, but with care and taste. No flower looks so untidy as that of a Carnation when left to sprawl at its own sweet will, and after blooming is over the stems should be cut away. On no account should propagation by layering be neglected; herein lies the great secret of a constant supply of young healthy plants short of raising from seed. Old plants will soon become leggy and ungainly, and the flowers thin and small; propagation by cuttings or pipings is far too uncertain to make me recommend it for adoption. If every year, during the early part of July, the amateur operator will select some of the best of the new growth, strip from the base a little of the foliage, give on the under side of the stem with a sharp knife an oblique cut half-way through, then with a trowel loosen the soil beneath, bury the cut portion in it, and keep it in its place by a stone, all is done that is necessary to secure for the next year an abundance of fine young plants that will afford bloom for several months. The replanting of this young stock each year should be something more than a mere formality. The Carnation will amply repay for any little extra labour that is expended upon it, even though the mission of its flowers be but to decorate button-holes. The soil should be deeply broken, and a little rotten manure added; and, when the layering is performed, a little fresh loam mixed with sharp sand helps the rooting. Frequently these layered plants will in the autumn throw up premature flower stems, that would be useless if left out for the winter, although some of the very earliest may, if the autumn be mild, expand their blooms up till the month of November. It is worth lifting up some of these precocious fellows with good balls of earth, and potting them up, as in the temperature of a greenhouse some of them are not unlikely to yield flowers through the winter, and will be certain to do so if kept in a little heat. A. D.

COLOURS IN THE FLOWER GARDEN.

M. BUFFON, a good many years ago, made a very interesting discovery, which is practically very useful, and very closely approaches in correctness the diagram principle in determining the colours which contrast. He discovered that if a wafer be placed on a white sheet of paper, and gazed steadily at for a few seconds, and then the eye removed to another part of the paper, a spectrum of the same size as the wafer and of its contrasting colour is seen. The spectra are, however, rendered more distinct when the wafers are looked at on a dark ground, and the eye then directed to a white ground. This simple fact is the reason why black printing is more comfortably and easily read on a white ground than red, for red would have a contrasting green spectrum floating before the eye on a white ground; white being the contrast to black, the spectrum is prevented in such a combination. By this simple process, as well as by the aid of the diagram, the colours at the disposal of the flower gardener can be arranged according to the law of contrast. The following is a table of the colours and their contrasts:—

Black . . . . .	White.	Green . . . . .	Reddish Violet.
White . . . . .	Black.	Blue . . . . .	Orange.
Red . . . . .	Green.	Indigo . . . . .	Orange Yellow.
Orange . . . . .	Blue.	Violet . . . . .	Bluish Green.
Yellow . . . . .	Indigo.		

These are the contrasting colours as determined according to Buffon's spectrum discovery; and it will be found that these results closely correspond with those determined by the rules of the diagram. The merest tyro will find the application of these rules of great service in the arrangement of flowers on the principle of contrast. Of course there are intermediate shades to be dealt with not embraced by the colours included in the spectrum; and just in proportion as these shades approach the various prismatic colours, so must the rules be modified and applied. Buffon's system can always be resorted to as a guide sufficiently correct for all practical purposes, and, if followed as closely as the various shades and different heights of plants will allow, cannot fail to be of great service in flower-garden arrangements. In coming to the practical application of these rules, some may perhaps find that it is not so easy as at first appears to deal with colours which do not exactly agree with those of the prism; nevertheless, the rules still hold good, and can be applied with more or less of a decided result. In order to illustrate this, take one or two of our most popular grouping plants which have not a facsimile in our table of contrasting colours. Take, for instance, Purple King Verbena, which may be described as a reddish blue. Looking at the prismatic colours, this approaches nearest to blue; it is blue with a shade of red in it, the contrasting colour to which is green or orange. The blue being in the ascendant in the Verbena, the contrasting plant must have orange in the ascendant as the contrast to blue; but the red in the purple demands a greenish shade, and consequently the contrasting plant must be a greenish yellow, such as we have in *Calceolaria amplexicaulis* and *C. canariensis*, &c. Then, if we take an orange yellow, such as *Calceolaria aurantia*, *multiflora*, or *Tagetes signata pumila*, we have orange yellow, or yellow with a shade of red, requiring for a contrast a greenish blue, and which is most nearly supplied in *Lobelia Erinus speciosa*. Our nearest approach to black is supplied by such plants as *Perilla nankinensis*, *Colens*, *Beet*, and a few others. Now, if we describe them as reddish black, the contrast of this is greenish white, and this is supplied by such plants as *Koniga variegata*, *Dactylis glomerata variegata*, variegated *Pelargoniums*, &c. From these illustrations it can be seen in how thoroughly practical a way the elementary rules can be applied. It is because of the law of contrast that the flowers of a scarlet *Pelargonium* are much more distinctly striking in the case of those varieties which have a dark green leaf without any variegation or zone, because green is the contrast to red. The most accommodating colour for contrasting

with others, with considerable distinctness, is white, or very light grey, such as *Cerastium tomentosum*, *Centaureas*, and *Cineraria maritima*—all of which may be used as a contrast to all strong colours, such as crimson, bronzy crimson, deep scarlets, blues, and deep purples.

*Arrangement of Colours according to the Law of Harmony.*—

Colours are said to harmonise when different shades blend insensibly into each other. This is easily detected by any one who has a perception of, or, as it is generally termed, an eye for colour. That which harmonises with any original colour is always next the original, and between it and the contrasting colour, in the order of the diagram. Following out this, it will be seen that red is the harmonising colour to orange, blue to violet, yellow to white, and so on. Practically speaking, harmonising colours are considered more easily detected than those which contrast. Take, for instance, red or scarlet, dark pink, pale pink, and white, and place them in the order named, and a pleasing harmony from red down to white is the result. The transition is gentle and beautiful. Then,

again, take a purple-flowering plant with a shade of red in it, and place it near a crimson, or let a golden-leaved *Pelargonium* be associated with some of our silvery-foliaged plants, and a most delicate and pleasing harmony is produced. These examples are enough to show what is conveyed by the term harmony of colours; and there are few things that afford more pleasure to an eye, however slightly trained to colour, than the contemplation of the soft gradations that may be worked out in a bed of flowers associated according to the principle of harmony. It is somewhat degrading to the art, to look upon it merely as a means of embellishment capable of only tickling the eye. Harmony and contrast may be illustrated with charming effect in one bed. What, for instance, can be more lovely than a centre of yellow, with a corresponding zone of white, finished off with a fringe of blue or purple? The two centre colours harmonise, while the blue contrasts. Or if two contrasting colours—yellow and blue—are mixed in the centre of a bed, and edged with red, which harmonises with the orange, the effect is very fine. In filling a bed with three colours in distinct zones, the two harmonising colours should be in the centre, and the contrasting colour as a margin. This principle of painting is particularly applicable to an isolated place, because the eye comprehends and grasps the design better with the soft colour in the centre than at the margin. With a strong colour for a centre, the eye is tyrannically attracted to the weight of heavy colouring. One of the most effective combinations of this mixed principle in one bed that I ever saw was the key-bed

Section of a Lean-to Orchid House (see p. 61).

Section of House adapted for Vines and Orchids (see p. 61).

From these illustrations it can be seen in how thoroughly practical a way the elementary rules can be applied. It is because of the law of contrast that the flowers of a scarlet *Pelargonium* are much more distinctly striking in the case of those varieties which have a dark green leaf without any variegation or zone, because green is the contrast to red. The most accommodating colour for contrasting

applicable to an isolated place, because the eye comprehends and grasps the design better with the soft colour in the centre than at the margin. With a strong colour for a centre, the eye is tyrannically attracted to the weight of heavy colouring. One of the most effective combinations of this mixed principle in one bed that I ever saw was the key-bed

of a large design. The centre was of Bijou (variegated Pelargonium), with a zone of Golden Chain Pelargonium. So far this was harmony. Then there was a border 5 feet wide, all round the bed, of *Gazania splendens* and blue *Lobelia* mixed, and a fringe round all of Little David Pelargonium. At intervals of 8 feet, in the centre of the border of *Gazania* and *Lobelia*, were single plants of *Centaurea ragusina*. In this composition the variegated Pelargonium harmonised with the golden Pelargonium, the golden Pelargonium contrasted with the blue, and the fringe of scarlet harmonised with the orange, while the *Centaurea* contrasted with the blue, and was in harmony with the orange. There was a repose and beauty in this gigantic bed which required a practised eye to discover and appreciate, and it was exceedingly suitable as a key or centre bed, which should always be soft and quiet.—*Handy Book of the Flower Garden.*

[We reprint the above in answer to a correspondent seeking information on that subject. In the main it is right and calculated to be useful; but experiments and treatises long posterior to the remarks of Buffon have much more fully defined the nature of the primary, secondary, and tertiary colours and their complements. For instance, it has been proved that a red object casts a green shadow, and a blue object an orange shadow; green, therefore, is necessarily the natural complement and contrast to red, as orange is to blue, and so, on the same principle, with the secondary colours. Violet, for instance, is a secondary colour, as being a combination of blue with red, and requires for a contrast a mixture of the complementary colour to blue, which is orange, with the complementary colour to red, which is green; therefore the complementary or contrast colour to violet is olive. M. de Cherveuil, director of the manufacture of Gobelin tapestry, published a most complete, and in fact exhaustive, treatise on this subject in the year 1839. It was entitled "De la loi du contraste simultané des couleurs," and is illustrated, literally, by thousands of instructive diagrams. It is a work which ought to be in the hands of every scientific gardener when planning decorative effects in a flower garden.]

#### LEUCOPHYTA BROWNEI.

For bedding purposes, in future, I would strongly recommend this plant. As yet it is questionable if it has been recognised in that capacity; indeed, it is a plant of moderately recent introduction, and possibly not to be met with in many collections. Last summer, having two or three spare plants, I tried one planted out in the ordinary garden soil, and was surprised at the result as regards its freedom of growth, and also the abundant produce of its white wiry stems, which could be compared to nothing more appropriately than to a mass of filagree work of the loveliest frosted silver. Besides these recommendations, I may add the further one that no rain—of which, by the way, we have had a more than bountiful supply during the past autumn—appeared to tarnish its beauty; nay, rather, owing to the absence of the woolly character upon which so many of our white-leaved plants depend for their character, the result of a good shower of rain was but to render its silvery whiteness purer.

The special purpose in flower gardening to which this plant is peculiarly adapted is as an edging plant, especially for small sized beds, and I have an arrangement in my mind's eye which I hope to carry out next summer, namely, to margin round a bed in which a nice bank of the beautiful *Muhlenbeckia complexa*, now established for years, will form the background, whose dark brown stems and tiny maidenhair-like leaves will form an admirable contrast on the one hand, and a margin of the dense variety of the mossy Saxifrage, with its carpet of brightest green on the other. I shall be much surprised if my new friend the *Leucophyta* does not find a fitting home in which to display its beauty to advantage. I have had my eye upon this plant for several years, but found it very difficult to increase in any quantity, its nature, when grown in a pot, being somewhat hard and woody. This difficulty I have by my experimental plant fully surmounted, and possibly some of your readers who grow the plant would be glad to have the result of my experience.

Last autumn, in the early part of August, finding my *protocypis* developing such vigorous growth, I took a number of the side branchlets off about 1½ inch long, with a bit of heel from the parent branch; for this operation I need scarcely add a sharp knife is indispensable. These cuttings were inserted in pots filled with peat and a good mixture of silver sand, moderately

firmly pressed down and topped up with silver sand, inserting about two dozen in each pot. I then placed the pots in a little frame that I use for propagating such things as I like to keep under my own eye, placed on a tan bed that had done duty for some six months, but still retained a little heat, and of course that heat—little as it was—was regular and constant. The removal of the glasses for an hour or so every morning after the first week, and a slight shading for a short time longer, constituted all the further attention required, the result being so highly satisfactory that only three or four of the cuttings damped off. I have never succeeded yet in blooming the *Leucophyta*, nor has it yet been figured that I am aware of. It is a composite plant belonging to the same section as the *Helichrysums*.

Possibly some of your readers may have been more fortunate in this respect; if so, I for one would be glad to hear what its floral characteristics are. I would strongly advise those who possess the plant to try spring propagation, subject to the same *modus operandi* as I have given for autumn, and I think if the plant is only in vigorous growth the result will prove equally satisfactory.

JAS. C. NIVEN.

*Botanic Gardens, Hull.*

**Euphorbia amygdaloides.**—This beautiful wool Spurge as an ornament to woodland scenery has very few equals. Being evergreen, it is useful all the year round, flourishing in moist and stiff soils where but few ornamental plants will prosper; mingling with Grasses and Ferns and flowering plants. It is of the easiest culture, and may be transplanted at any time during the winter months, and will flower well the following spring. I can recommend this plant with confidence, as one that will beautify and give variety to woods and the rougher parts of pleasure grounds generally. It sports into many beautiful variegated forms splashed and striped and evenly margined with white, cream, and yellow. These variegated forms are not easy to increase; they are suitable for a border of variegated hardy plants. I have an entirely yellow variety, and shall be curious to know if it will reproduce itself from seed; if so, it will be generally useful.—Wm. ELLIOTT, *Beech-mount, Siblegham.*

**New British Variegated Grasses.**—I observed during the past summer some fine new varieties of our native Grasses; one, I think, will be very interesting, as it is a tricolor—*Brachypodium sylvaticum*, variegated with pure white, yellow, and green. This Grass is well adapted for Ferneries. *Brachypodium album variegatum* is a curious form of this Grass, with a thin vein of white up the centre of each leaf, and the flower-stems are entirely white. Another good Grass is *Anthoxanthemum odoratum arenum striatum*; this makes a fine tuft, and will flourish in stiff and bad soils. *Holcus mollis aureus* will be useful, as it is a fine colour during the summer months, and good for rockery, wood, or wild garden. These three Grasses are all from Dulwich wood. I have others that are very interesting, such as two variegated forms of *Luzula pilosa major*, a *Carex*, another *Holcus lanatus*, and I think a *Bromus sterilis*.—Wm. ELLIOTT, *The Gardens, Beechmont.*

#### NOTES AND QUESTIONS ON THE FLOWER GARDEN.

**Chamaebatia foliolosa.**—About ten years ago I saw a small plant of this on a gentleman's lawn, and its exquisite foliage so charmed me that I at once resolved to add a specimen of it to my plant collection. I applied to many of our leading nurserymen in England for it, but could never succeed in obtaining a plant. The name occurs in many catalogues, but the reply to every enquiry made concerning it is the same, "regret we cannot supply it." How is this?—J. M. HAWKENTRUP, *Aminston.*

**Primroses.**—I have *Primula alicata* at present in bloom at Bedford. It is of a pale mauve colour and is extremely pretty and effective. I have also a great variety of crimson shades among some seedling Primroses which I have raised, but nothing to touch *P. vulgaris auriculata*, blossoms of which I enclose. It is wonderfully floriferous, and on the bright sunny days of early spring very beautiful indeed.—RICHARD DEAN, *Ealing.* [Along with this came a boxful of Primroses, varying in colour from mauve to crimson; but the best among them were decidedly those of *vulgaris auriculata*, each of which is larger than a shilling, and has a bright yellow eye, which sets off the rich velvety crimson of the rest of the flower to much advantage. It is a charming variety.]

**Mildness of the Season in Anglesey.**—It may interest some of your readers to hear what a mild climate this locality possesses. On Sunday I gathered a white Camellia from a tree in our garden, and some more since. This tree is 6 feet high, and about as many in diameter. It was planted out about fifteen years ago, and every year it is covered with blossoms. Last year I cut the first flower on the 26th January, and from that time till March, when they were blighted by the frost, I was able to cut many every day. On Christmas day I gathered a bouquet of *Mignonette*, *Roses* (tea *Goubalt*), scented *Verbenas*, (*Aloysia citriflora*), and a *Carnation*, all from the open air. Many flowers are now in bloom, night-scented *Stock* being among them. The *Calceolarias*, *Verbenas*, and *Geraniums* which were left in the ground are all as fresh as possible.—ANNIE OWEN, *Tregarth Rectory, Isle of Anglesey.*

## THE ARBORETUM.

### HARDY TREES AND SHRUBS.

BY GEORGE GORDON, A.L.S.

#### THE SIBERIAN MAPLE (ACER LOBATUM).

THIS forms a small tree from 20 to 30 feet high, with a somewhat dense rounded head, amply furnished with lateral branchlets thickly garnished with tufted leaves, and when leafless with downy buds. It is a native of Asiatic Russia, on the Ural and Caucasian mountains, and in the wooded regions of Tobolsk, in western Siberia. It was first introduced in 1838. The leaves are somewhat small rounded in outline, slightly cordate at the base, and five lobed, with the divisions open and moderately deep. They are leathery in texture, bright green above, pallid beneath, smooth on both

A. lobatum (a full-sized leaf).

surfaces, and set on long footstalks, which are frequently of a deep red colour. The lobes are rather broad and toothed on the edges, with the three outer ones equal in size, semi lobed, and the largest. The flowers are in drooping corymbs, yellowish-white, and produced in May. The fruit or keys are rather small and smooth, with thick carpels furnished with rather broad wings slightly spreading. The Siberian Maple forms a nice small tree for planting singly on the lawn, on account of its slow growth and neat appearance. The leaves before they fall off in the autumn turn to a beautiful bright yellow tinted on the upper side with red. It is sometimes named *Acer caucasicum* in the nurseries. Length of a full-sized leaf, 5 inches, including the footstalk, which is frequently from 2½ to 3 inches long; breadth of leaf, 3 inches.

#### ABIES DOUGLASHI AS A FOREST TREE.

A VERY fine specimen of this Fir may be seen growing in the grounds at Hackwood Park, Basingstoke, and, owing to its quick growth, this Fir would doubtless make a valuable forest tree, especially as it can now be procured in quantities at a cheap rate. The tree in question has been planted, as near as I can ascertain, about forty-five years. It is now over 90 feet high, and more than 10 feet in circumference at 3 feet from the ground, and it has a spread of branches 50 feet in diameter on the surface of the ground. It is growing on a strong hazelly loam, in which *Rhododendrons*, and in fact nearly all sorts of shrubs do well. Near it are growing some very fine Silver and Spruce Firs, some of the former being over 100 feet in height, and 10 feet in circumference above the ground level, and one specimen of the latter is the same height, and 16 feet in circumference, at 4 feet from the ground. During the time I had charge of the place, viz., six and half years, the Douglas Fir increased 16 inches in the

circumference of the bole. There is a pale-green foliaged Douglas Fir in commerce, but the true sound sort has very glaucous leaves. Whether the green kind is the produce of weak, unsound, home-grown seed or not, I am not in a position to say, but I would caution intending planters of this tree on a large scale to be careful to procure the glaucous-leaved variety, to plant it in good sound leamy soils, and not in exposed situations. Under such conditions the probability will be that it will prove a useful tree for forest purposes, and also have the additional recommendation of being a handsome tree in reference to landscape effect. It will not succeed, however, except it be planted in good leamy soil. I say this advisedly, for when I planted it on thin soil near the chalk, its progress was not satisfactory. Mr. Barven, of Elvaston, who strongly recommends the Douglas Fir as a useful tree for forest planting, says that the timber is equal to that of Pitch Pine.—H. C. G.

#### CONIFER HEDGES.

IN reply to the query of "J. H. W. T." viz., "Which of all the Conifers would in five years make the best hedge as regards graceful habit, colour, and denseness?" I can, from experience, give my opinion in favour of the *Abies excelsa*, or Norway Spruce. The gracefulness of its habit may perhaps be doubted, but in brightness of colour and denseness it can hardly be surpassed. I have seen it much used in France, Bavaria, and Austria, as garden hedges, screens, and railway fences. To ensure the success of a Spruce hedge, care should be taken to select thriving plants that have been several times transplanted, say 2 feet high, having well-preserved branches at the base of the stem, and planted in a double row on well-trenched soil. In the annual pruning or trimming of the young plants it is requisite that the top of the hedge be left narrower than the base, for an even admission of light; neglect of this particular invariably checks and eventually destroys the under branch growth—an irremediable evil in the case of all ever-green Conifers. I should say that five years is too short a period in which to expect the full growth and perfection of any Conifer hedge. E. D. T.

Welfield.

**A Mistletoe Mystery.**—Three times in one week a lady asked me if I had heard the tradition that the Druids cursed Devonshire, and forbade their sacred plant to grow there. Once I answered "No;" twice just as truthfully "Yes." Lest any of your readers should be as ignorant as I was in the first instance, I hasten to assure them that the Devonians believe this to be a fact; and that a friend of my informant having orchard ground in Somersetshire and Devonshire, the two portions being divided merely by a deep ditch, has tried in vain to propagate the parasite on his trees in the county under Druidic ban, whilst it grows in almost troublesome profusion on those just over the border."—ST. SWITHIN, in *Notes and Queries*. Mr. Barnes says in reference to this matter that when at Bicton he never succeeded in getting Mistletoe to grow from seeds, which, on several occasions, he rubbed into the chinks of the bark of Apple trees, and he adds that he never saw Mistletoe grow on any tree in Devonshire, although he has heard that it does grow somewhere in that county.]

#### NOTES AND QUESTIONS ON TREES AND SHRUBS.

**Euonymus radicans.**—Like Ivy, this is an excellent plant for attaching itself to walls and hiding them; and like Ivy it will thrive in the shade. It can also be employed for covering the earth, where little else will grow.

**Sambucus racemosa spectabilis.**—This is one of the prettiest of shrubs, and one which is extremely hardy. It grows to a good height, and in April becomes covered with innumerable clusters of white flowers, which are slightly sweet-scented. It is highly recommended as an ornamental shrub by M. Carrière.

**Road-side Trees and Telegraph Wires.**—Mr. Brewin, Culland Hall, Derby, has requested us to say that if the gentleman alluded to in a communication under this head in one of our recent numbers will communicate with him, he thinks he can procure for him information that may be valuable as regards the serious and unjustifiable injury which the Telegraph Company appear to have inflicted on his property.

**Pruning Conifers.**—Mr. McNab recently read a paper "On the effects produced by stem-pruning small plants of the Nidpath Castle Yew," at a meeting of the Royal Botanic Society of Edinburgh. Stem-pruning of plants of this variety of Yew continued for several years after they were struck from cuttings, induced them to become infinitely more graceful than either the Irish or the unpruned Nidpath Castle Yews.

**New Ornamental Cherry.**—It may interest your readers to know that a peculiarly singular sport to that described in the *Belyne Horticult.* and quoted in "THE GARDEN" (p. 5), has occurred in this neighbourhood. When at Selby last autumn I saw in the garden of Messrs. Smith and Son one year's shoots of a cherry with leaves such as are described, whilst other leaves from the same bud had the ordinary character of those of the parent tree, from which it had been taken. A more striking sport or deviation from the normal type I do not remember to have seen.—J. S. GRAY, York.

## VEGETATION IN CENTRAL AFRICA.

THE spirited dash made into the depths of unexplored Africa by Mr. Stanley in his search after Livingstone, has clearly shown to the world that the central and hitherto mysterious regions of that vast continent are by no means so inaccessible as has been thought. He has, indeed, proved that with moderate prudence, a tolerable constitution, and an escort, comparatively unarmed, consisting chiefly of porters to carry a supply of provisions, with cloth and beads to barter for necessaries, any man may penetrate to the great lake district, either with the views of a sportsman in pursuit of "big game," a trader seeking to share in the lucrative traffic in ivory, or a man of science in search of knowledge. Here, indeed, is new ground for the exploring botanist; a new field of discovery, in which he may reap a splendid harvest of novelty and beauty. The hasty glimpses of recent travellers, especially Stanley, have made known new mountain ranges, the flanks of which, at different elevations, may prove as fertile in splendid additions to our gardens, shrubberies, and woodlands as those which have quite recently become known to us for the first time from the grand botanical regions of the Himalayas.

Mr. Stanley's snatches of broad, general description of the forest and jungle scenery which he passed through are often very spirited, and present us with touches of great graphic power. In the district of Mwapa, for instance, he noticed "precipitous scarps where clung the Kolquall with a sure hold, drawing nourishment where every other green thing failed; and clad in others with hardy Mimosas, which rose like a back of verdure almost to the summit." There were, as he tells us, "mountain vales, containing deep recesses which might charm a hermit's soul; and awful ravines where reigned a twilight gloom, or fractured and riven precipices," which produce the deepest impression on the traveller. In another place he describes luxuriant forest hollows where the giant Baobab and the great African Sycamore mingle with Palm and Plantain in matted rankness, and where the rhinoceros and many other kinds of "big game," undisturbed by hunters, fearlessly approach within a short distance of his camp, presenting just such a scene as that exhibited in the accompanying engraving. When an elevated position could be reached, the view over the forest tops is thus described:—"An illimitable forest stretches in grand waves far beyond the ken of vision. Ridges, forest-clad, one above another, until they recede into the dim purple-blue distance, with a warm haze floating above them, which, though clear enough in our immediate neighbourhood, became impenetrably blue in the far distance. Woods, woods, woods—leafy branches, foliated globes, or parachutes—green, brown, or sere in colour, forests one above another, rising, falling, and receding—a very leafy ocean." And then, comparing small things with great, he exclaims that, although the grove of the Central Park, New York, is grand compared with the thingroves seen in other cities, and Windsor Forest and the New Forest are noble, as compared with other forests in England, they are yet but "faggots of sticks," compared with the eternal forests of Unyanyemwezi.

Mr. Stanley puts forth no pretensions to accurate scientific knowledge of natural history, in any of its branches; but with the quick perception of a man of genius his attention was caught at once by any striking novelty which he met with. General scenery, endless varieties of quadrupeds, birds, fishes, insects, and plants; everything that fell in his way received some hasty notice in his journal, regularly kept up despite all difficulties, and the rapidity of the hasty push forward, necessitated by the nature of his enterprise, which was not one of scientific research. He found time for furnishing us with the following summary, in brief, of some of the great forest trees, shrubs, and other plants which he observed in the great lake region. Taken altogether, he says, Unyanyemwezi may be said to be the finest country in the whole of East and Central Africa; it is one grand rolling table-land, with a gentle western trend towards Lake Tanganika, which drains the greater part of it. He then gives just such a graphic account of the precise nature of the scenery as would delight a landscape painter, and make him long to transfer such models to his canvas. His remarks on the different hues of the foliage, from the tenderest greens verging on white, to the deepest purple, though without definition as to individual plants, are more than sufficient, vague as they are, to raise the brightest dreams of brilliant discoveries in the imagination of the botanist. He then proceeds to describe, in slight detail, a few items of this glorious vegetation. The most gigantic tree in the region of the Tanganika appears to be the Mtumba, a species of Sycamore, which is equal in size to the gigantic Baobabs of Ugogo and other parts of Africa. It bears a Fig-like fruit, much esteemed by the natives, and which is of pleasant flavour. There are many other trees of great grandeur of growth, among which are those the natives name Mtunda, Miombo, Mkora, Mkurongo, Mbemba, Mvule, Msundurasi, Muinga, Mbugu, Matonga, and Mbite. The last-named, the Mbite,

furnishes timber as beautiful and as sweet as Cedar; it is marked with red and yellow veinings, and is used ornamentally by the natives in their better kind of structures. The Mkora is a large tree of very stately proportions, the wood of which is durable and handsome; the stools of chiefs, often richly carved, are formed of it, as also the huge mortars in which the Sorghum grain is pounded into flour. The Mkurongo, another grand tree, furnishes the wood from which the great pestles for pounding the grain are made. It is harder and more durable than Hickory, and when polished has a whitish and glistening appearance, like a metal. The Mbugu, a very ornamental tree, furnishes a soft, fibrous bark, from which rope, coarse cloth, and light boxes are made. The inhabitants on the banks of the Rufigi also construct small canoes with it; but it is from the grand Mvule tree that the lake tribes construct their largest canoes, often above 60 feet long. This enormous tree attains its greatest size among the mountain ravines of Ugoma. Among the other remarkable trees of the great lake forests are the Kolquall, or candelabra tree, a fragrant Mimosa, the Guinea Palma, called Mehikichi, and the Plantain tree. The Cactaceans and Alocetic plants are found all over the country, and doubtless many new and beautiful kinds of these favourite families of plants would reward the researches of the adventurous explorer. The Tamarisk trees attain great size to the west of Unyanyembe, and many kinds of Tamarind and Acacia appear to be well worthy of notice, as exhibiting many striking varieties.

Among fruit-bearing trees, the Imbembu or Wood Peach appears to be one of the most interesting; and the fruit, under culture, might become a very delicious novelty. There is also the Singwe or Wood Plum and the Mtgowo or Wood Apple. In Ukawendi there are many kinds of Grapes, some of which promise to reward the careful cultivator. Many of these African fruit trees, if not always amenable to European culture, with profitable results in themselves, might possibly be extremely valuable for hybridising, and imparting new vigour and distinct characteristics to some of our old and, in occasional cases, nearly worn-out strains. Many of the African fruit-bearing trees have, it appears, been brought into a kind of garden cultivation by a colony of Arabs at Unyanyembe, who have also been very successful in the culture of the Orange, the Citron, the Lime, the Papaw, the Guava, the Pomegranate, the Mango, and the Banana. Large kinds of field and garden Beans are in common culture among the natives, as well as Rice, but wheat is only grown by the Arabs. Sweet Potatoes, Yams, and Manioc are abundant, and the sugar-cane flourishes at Ujiji. The harvests of the region take place once a year, in April, May, and June, according to the elevations of the districts. Cotton, tobacco, the Castor-oil plant, sweet Gourds, and Cucumbers are also plentiful. Among the lesser shrubs and plants Mr. Stanley notices indiscriminately the wild Thyme, a dwarf Holly, the Sun-flower, several Poppies, Bird Pepper, Chillies, Ginger, Turmeric, wild Mustard, and the Curry plant.

In the forests bordering the great lake it would seem that a magnificent harvest of beautiful and highly-desirable shrubs might be collected. Mr. Stanley speaks enthusiastically of hundreds of kinds bearing beautiful flowers, which exhale an exquisite fragrance. Among water plants we are told of the Lotus, the leafless Lily, several kinds of Papyrus, the Matile Cane, and the marsh-growing Pith tree.

Looking at this list as the random jottings of a traveller whose observations were the result of partial glimpses snatched at intervals during a rapid and continuous journey towards a special goal, it surely affords most tempting indications of botanical riches which are waiting in their beauty as prizes for the first enterprising explorer. That many of the plants might prove suitable to a temperate climate is plainly suggested by the existence of the wild Thyme on the hill-sides, by the culture of wheat as well as rice in the plains, and by the fact that many of the trees, shrubs, and herbaceous plants alluded to are found at considerable elevations in the mountain ranges. Why do not one or more of our enterprising and wealthy nurserymen send out a collector at once? The surface of our planet is getting rapidly ransacked; but there is, as yet, a grand opportunity of acquiring something new, something worth while, in the alpine regions of central Africa, and it is now shown that for the outlay of £1,000 a collector might be sent to the glorious shores of Tanganika. For that comparatively small sum he might both go and return; bringing back with him such a harvest of botanical novelty as would yield enormous profits, if profit alone were sought.

H. N. H.

**The Struggle for Life among Plants.**—Each plant endeavours, almost consciously, to destroy his neighbour, to occupy his ground, to feed upon his nutriment, to devour his substance. There are armies and invasions of Grasses, barbarian inroads and extirpations. Every inch of ground is contested by the weeds; the forest is a struggle for precedence; the wars of the Roses are a perennial feud. The severest landscape, the stillest woodland, are the mortal arena of vegetable and animal conflict.

VEGETATION IN THE TRAIL AFRICA

## THE PROPAGATOR.

### ON GRAFTING AND BUDDING.

BY A. MURRAY.

THE drawings and woodcuts which are given of the process of grafting, by the most eminent writers on the subject, almost always convey an erroneous impression on the very point on which success entirely depends. The woodcuts of the slips and grafts prepared for adhesion turn the attention more to an equality of dimension, and to a correct fitting of the outside of the bark of the one to the outside of the bark of the other, than to an exact apposition of cambium of the one to that of the other, on which, in point of fact, adhesion and grafting absolutely and solely depend. Most people know that in all instances of transfusing a part of one plant into that of another, whether by grafting, or budding, or any other mode, the only point at which transfusion or union can take place is the outer circle of vessels which lies between the bark and the wood, in which the passage of the sap alone takes place, and by which the connection between the roots and the leaves, and the consequent deposit of wood and growth of the tree, take place. I am afraid, however, that the more general impression is that a branch grafted on to another is united to the stock on which it is grafted throughout its whole surface, that it grows together as two parts of an animal body united by the first intention do, as, for example, part of a finger cut off and immediately clapped on again. The examination of sections of old grafts will serve to correct any such misapprehension. They show that there is no union whatever at any part of the wood of the scion applied to the wood of the stock, except solely at the outer ring of the albumen, already mentioned; indeed a small film of a brownish substance is deposited along every part of the applied surfaces, except the outer ring, where the union takes place; and some specimens of sections of grafts show isolated deposits of wood and woody fibre enveloped in this brown deposit, which I imagine to be oozeings of woody matter something analagous to what is called prond flesh in the animal body. What I wish, however, particularly to point out is that in every instance the inner part of the applied surfaces where the union has not taken place, both of the scion and the stock, is in a more or less advanced state of decay. In no instance is this absent, it is an inherent necessity in the very process of grafting that the seeds of decay be shut up along with it. In fact one inevitable ingredient in the manufacture of grafts, concomitant, coexistent, and inseparable from it, is the simultaneous manufacture of an ulcer in its heart. Exactly the same thing takes place in budding, although on a smaller scale—the larger the extent of the cut surfaces applied to each other the greater being the extent of future decay; and of course in budding this space is small in comparison with that in grafting; and of course, too, the smaller the amount of exposed surface or cut wood the less will be the amount of ulcer or decay subsequently manifested in the heart of the branch. I was about to say that the smaller the amount of this surface, the greater would be the skill of the operator; but this would imply that the decay in the heart of the branch was injurious to the plant, and was, if possible, to be avoided; and I am not sure that we are to take this for granted. Of course, if we want a perfect tree complete of its kind, doing all its functions in the best manner for itself and the general purpose it is to serve in organic nature, we must say that it would be better without the decay in the heart of the graft, and that that decay must be looked upon as a blemish; but that is not what we want in every case of grafting. In fruit trees we do not want a normal amount of fruit; we want an excessive amount. In Rose trees our demand for flowers is not limited to Nature's natural bounty; like Oliver, we come back for more, not once, but many times. Now it is well known that one of the surest means of inducing an excessive production of flower and fruit, is to weaken the vitality of the plant. It is no uncommon thing to hear people say that a plant had killed itself by its excessive flourish the previous year, whereas it was not the flourish that killed it, but the plant, knowing that it was going to die, made a desperate effort to propagate its species before its life was extinct. Now, if the implanting of decay in the heart of a tree is injurious to the health of that tree, it may have the effect of inducing something of this excessive effort at propagation. I have heard it said that grafted trees always bear better than ungrafted; but as to that we have plenty of practical men who can speak with authority. It is to be observed, too, that the decay of which I speak is limited in its extent and slow in its progress. It is shut up and almost hermetically sealed in by the deposits of wood which have taken place subsequently to the union of the graft; and although I have called it an ulcer, it is only so in the sense of being a source of decay; there is no active or malignant principle at work; it is merely the gradual decay of a perishable body which is situated in the heart of the timber.

It may be asked, too, whether this decay in the heart really does

any damage other than weakening the branch or stem at the point where it exists; for it cannot be disputed that to that extent at least it must be injurious. Is the heart of the stem of a tree of any use to it except for the support and solidity which it gives it? We see old piped trees flourishing away after all the heart is gone, and nothing left but a thin rind. True, the flourishing is not so vigorous as in a younger and more solid tree. No great sturdy arms are thrown out, and the foliage is limited to a few clustered, scrubby twigs. But it does not follow that this weakness of growth is due to the tree being piped. In such cases, we must remember, that tree has generally been growing in the same ground for perhaps hundreds of years, exhausting all the ingredients of the soil which are suitable for elaboration into its sap and fibre—and that if we remove the tree and plant another of the same kind in its place, it grows no better than the old one, seeming to show, at all events, that it is not the mere absence of pith and heart-wood in the old tree which has caused the declension in its vigour of growth.

The principles of physiology, therefore, would rather seem to say that in all those cases (such as fruit-trees, Roses, &c.) where the acquisition of solid timber (whether for the support of the tree or for the uses of man) is not the principal object, grafting, although attended by decay, is not attended with consequences injurious to the purposes for which the tree is cultivated. But where timber is the object, as in forest trees, the case is different. The decay imbedded at the base of the stem gives an element of weakness to the tree at the very point where the leverage of the wind is strongest, and exposes it to be snapped off at the root. I do not think it can be said to be injurious to the growth of the timber in other respects; for immediately above the graft the timber is deposited in a solid and continuous stream; and I see no reason why the tree in all other respects should not be as good as an unworked plant. Still we have a prejudice in favour of seedling trees; and I think that the liability of grafted plants to breakage from wind is quite a sufficient reason why we should continue to retain it.—*Journ. Roy. Hort. Soc.* 1873.

**Mistletoe.**—A few years (four or five) ago a man in the village where I reside put some berries on my trees, and in nearly every instance they grew. He merely squeezed the inside free from the skin on to the young bark of Apple and other trees. They of course adhered of their own accord. The spring was fairly wet, but the summer was dry, and some of the young shoots died off. I have now large plants in the case of those which were not killed off. Each year I tried other berries; but, owing to dry summers, the shoots died off. Last spring and summer were wet, and I have now every shoot living, and the trees in a few years will be covered with Mistletoe.—*Charles Bumford.*

**Experiments in Grafting.**—The *Profric Farmer* has published in detail the experiments made at the Illinois Industrial University, on root grafting the Apple. The results are—1. That grafts set on the first cut of the root or collar are more apt to live than those on lower cuts of the root, although the difference was not striking. 2. That the first or lower cut of the scion is more apt to live than those taken higher up. 3. That the terminal bud did not succeed so often as other grafts, but generally made a longer growth. 4. That when cuts of the roots four or five inches long were used, they lived oftener than 2½ inch cuts, and more than twice as many grew as when the cuts of the root were an inch and a half long. Single experiments like these, however, need repeating several times in different years, and under varying circumstances, to be trustworthy.

### THE LANGUAGE OF FLOWERS.

"TEACH thee their language? Sweet, I know no tongue,  
No mystic art those gentle things declare;  
I ne'er could trace the schoolman's trick among  
Created things so delicate and rare.  
Their language? Prithce! why, they are themselves  
But bright thoughts syllabled to shape and hue,—  
The tongue that erst was spoken by the elves,  
When tenderness as yet within the world was new.  
"And, oh! do not their soft and starry eyes—  
Now bent to earth, to heaven now meekly pleading,  
Their incense fainting as it seeks the skies,  
Yet still from earth with freshening hope receding—  
Say, do not these to every heart declare,  
With all the silent eloquence of truth,  
The language that they speak is Nature's prayer,  
To give her back those spotless days of youth?"

**A Turkish Crystal Palace.**—The late Sultan, wishing to give an idea of the Crystal Palace at Sydenham, commissioned a firm to construct the iron framework of a huge dome-like structure. It was, when completed, put up in England, and then taken to pieces for conveyance to Constantinople, where it was re-erected and covered in with glass, and formed one of the most conspicuous and pretty objects which met the traveller's gaze on going up the Bosphorus. The present Sultan, however, thought that it interfered with his view, and ordered it to be demolished, and the debris of a building which from first to last must have cost more than £100,000, has been sold for old iron.

THE BEAUTY OF BARE BRANCHES.

THE matchless sculptors of Greece—though the national Chlamys, pallium, and peplos were, perhaps, the most graceful forms of drapery ever devised for the clothing of the human body—considered that both man and woman, made in God's image, were, "when unadorned, adorned the most," and the masterpieces of their art, which they have bequeathed to us, seem to leave but little doubt that they were right. May we not, to some extent, adapt the Greek theory of beauty to our deciduous trees, when they let fall their summer mantle of green, and stand confessed in the naked beauty of their wondrous elegance of forms, spreading themselves forth in a thousand varying ramifications, each more wonderful and graceful than the other. We need but to cast a single glance at the elegant dismantled Lime, engraved below, to be convinced of the greatness of tree beauty as it appears, unclothed, in winter.

There is in the Lime a graceful drooping of the lesser branchlets, like slender fingers to the thousand hands of some delicately-formed Briareus, which is irresistibly attractive. In fact, the Lime is so beautiful when undraped that I have often felt a certain sense of regret when spring, with her train of tiring maids, has arrived in early April to introduce the vernal fashion of mantlers first of all to the exquisitely graceful Lime. The bare-branched Oak displays another kind of beauty. Great brawny limbs spread themselves forth from the majestic trunk in daring grandeur and robust power, reaching straight out to incredible distances; each great branch supporting masses of gnarly ramifications big enough to form a separate tree. Next in stately grandeur comes the Elm, little inferior in majesty to the Oak. Then follows the Ash, with branches of pearl grey; and then the feathery Birch, the cynosure of elegance, with silvery skin, that glistens in the rays of the winter sun with a semi-metallic lustre; and how many others of our noble deciduous trees might be mentioned, as equally beautiful?

In strong and massive contrast to the nude leaf-shedding trees, we have, during the winter months, the dark green masses of the Pine tribes, which, in the absence of more vivid greens, display their sombre tones of dark olive to great advantage.

There is the great Mountain Fir, for instance (see p. 75), which, with its massive trunk, often made conspicuous by a hoary clothing of Lichen, which droops from its horizontal branches like a venerable beard, groups well with the trees whose bare trunks and branches are unsupported by a thick background of green. With this, too, the foliage-shedding Larch forms

an interesting contrast, forming a link between the evergreen Pines and the deciduous trees of ordinary character. We should have in our gardens only a monotonous kind of enjoyment if we were sentenced to perpetual summer. It is a great relief to be freed for a time from a surfeit of floral splendour, and the continual prevalence of rich perfumes, such as those which Rose and Woodbine, and Jasmine, and a hundred other sweet-breathed flowers exhale. The prevalence for a time of bare branches and keen breezes is not only delightful as a contrast to continued banqueting on gorgeous colour and luscious sweets, but the aspects of the time are beautiful in themselves; and the bracing winds of winter which accompany them prepare us, like a tonic, for another course of summer beauty. The winters in the south of Europe, where vegetation wears very much the same aspect all the year round, present no such changes to vary the successive aspects

of the year; and consequently, the coming of spring is not hailed with anything like the zest which it inspires in our own climate, where we set to work as soon as the first green, and the earliest flowers appear, to wreath fresh garlands and to weave new bowers—

With twice the ecstasy  
of one  
Who has no wintry  
season known.

H. N. H.

The Lime Tree in Winter.

**The Rainfall of 1872 at Cheltenham.**— My house stands on the west side of a down, a spur of the Cotswold Hills, about 215 feet above the lowest part of the valley in which Cheltenham stands with a north-west exposure. Here the total rainfall of the year has been 38.60 inches. The months in which the greatest fall occurred were January 4.60 inches, October 3.95, November 4.77, December 3.19. The days on which the largest falls were registered were 4th January, night, .73 inch; 23rd January, .83 inch; 25th July, 1.38 inch, all of which fell in a thunderstorm; 30th July,

.81 inch, in the course of two or three hours; 7th August, 1.23 inch, with heavy thunder and lightning; 23rd November, .83 inch; 17th December, .81 inch; 25th December, .45 inch, fell in an hour, 10-15 a.m. to 11-15 a.m. I have only kept a register of the thermometer for the last four months. 13th October, night temperature, minimum, 29 Fahrenheit; 14th October, ditto, 27; 5th December, ditto, 26; 28th December, ditto, 46; 29th December, ditto, 42. In some of the nights, when the temperature was so high, that of the day was sometimes even lower, and never more than 2 higher. The wind on the night of the 31st December was south, thereby indicating, according to the ancient legends of northern nations, that we shall have "much warmth and growth."—K.

**Weight of the Late Rainfall.**—It is estimated that the fall in England last year amounts to 50,000,000,000 tons. We now can see what a powerful agent water must be in a geological point of view.

## THE FRUIT GARDEN.

### FORCING THE PEACH.

THE Peach is a more critical subject to deal with than the Vine, particularly in early forcing. A Vine, if it is at all in an ordinarily healthy state, may be reckoned upon almost constantly to produce fruit; but with the Peach, failure, when it does occur, is often complete. It is not forced early so much as the Vine, however, and this, together with the fact that it has not been written so much about, accounts, I think, for the failures that often happen with early crops. It is perfectly practicable to secure a crop of fruit the second year after planting, even though we begin with young trees, which is not always necessary when trees six or seven years of age can be procured. The construction of the house for early work is a chief consideration. I know many very imposing structures for forcing the Peach and Vine which are anything but adapted to the end in view—dead walls 3 or 4 feet high in front, and the roof pitched at an angle which would lead one to suppose the designer imagined the sun to be nearly over his head in December and January. The Peach house here is not a pretentious structure, but it is well set to its work, being a lean-to, thrown against a south wall pretty nearly at an angle of 45°, and so low in front that the trees, which are all trained under the glass at the same angle, get the sun down to their lowest branches, and not an inch of space is lost. The permanent trees are planted in front, roots outside and inside, and the branches have of course an area nearly equal to the roof in superficial extent to extend themselves. This is a better plan in every way than having a trellis only half-way up the glass in front, in order that the top half of the back wall may be covered with riders. In the first place, by the latter plan neither the front trees nor the back ones have half the room they require to extend themselves, and in a few years give infinite trouble to keep them within bounds and get fruit at the same time, especially the front trees. The riders at the back very often don't thrive well—they do not lie at a favourable angle to the glass; and, if the house is used for storing purposes during the winter, the roots get sodden and wet, unavoidably, and the result is altogether unsatisfactory.

A Peach tree, if allowed to extend itself, as it should be, would probably cover 400 square feet in seven or eight years, or less. It is therefore evident how utterly absurd the practice is of cramping such a vigorous-growing tree into a space 8 feet or 10 feet square, as it often is, in houses which are planted back and front. But by covering the inside of the roof with a wire trellis, a foot or rather more from the glass, planting the trees in front, and giving them the whole of the space to run over, all these evils are avoided, and the back wall during the spring months may be utilised for growing Strawberries or anything else upon. I need hardly say that ample ventilation should be provided, back and front, and arrangements should also be made for removing the lights after midsummer, so that the trees may be exposed to the weather till November. This is a very important matter. If young trees are planted, those which are intended to be the permanent ones should be planted in front, 20 feet apart (if that space can be afforded), selecting such varieties as will give a succession of fruit, and the spaces between should be filled up with supernumeraries (one in each space, perhaps), which will leave a space 10 feet wide for each tree. This being done, a row of riders should be planted along the middle of the house, the same distance apart, and so as just to catch the trellis about half way up the roof. It will be understood, I hope, that the whole of these riders, together with the supernumeraries in front, are intended to be cut away as the permanent trees overtake them, and eventually to be removed altogether. Vigorous young trees planted in this way, started in February, will generally be from 6 feet to 8 feet across at the end of the first season, and furnished with bearing wood, which should be hard and ripe by August or September, if all has gone well. By November the leaves will have fallen off the trees, and they should then be gone over and the wood thinned out where too thick. All the old ties should also be cut and removed, and the branches, which should always be trained above the wires, ought to be set perfectly free, and allowed to lie untied until the fruit is stoned. Some may think this is a trifling matter. I can only say that from careful observation and experiment I have become impressed with the conviction that it is a point of much importance. I find that Peaches and shy-setting varieties of Grapes set a great deal better if left free until the fruit is set, and for this reason I tie neither Peaches nor Muscat Vines until after this period. Tied tightly and stiffly to a wire is not a favourable position for the shoots to be in at the critical setting period. Fruit growers generally find that nailing in the shoots of wall trees, or tying in those of cordons tightly, as they progress, hinders their growth; and it is quite as likely that

the setting of the fruit may be injured by the same means. That it is so I have myself no doubt.

Having washed the house down, the trees may be started the second season about the beginning of January, at a temperature of 45° by night in mild weather, which may be pushed up to 55° by fire heat on dull days, and to 75° with sunshine and air, to subside at night, however, when this is reached, to 40° or 35°. When the trees come into bloom in February, the night temperature may range from 50° to 55° in mild weather, and from 60° to 65° on dull days by fire-heat; while, if the weather is frosty and the days sunny, it should run up to 75° or 80° at noon, always with a moderate admission of air, back and front, and fall at night to 40° or 45°. On fine days the trees should be dewed liberally overhead all the time they are in bloom, as well as at other times, with clear, soft, tepid water, about three or four o'clock in the afternoon. This restores the flagging energy of the flowers after a dry sunny day, aggravated by the hot pipes within the house, distributes the pollen more effectually than it can be in any other way, and is one of the greatest aids to a good "set" of fruit that I know of. That quite the contrary is the practice with many growers, I am aware. This has been my plan, however, for years, and the fruit sets always so thickly as to be quite troublesome to thin. But the dewing is only recommended when the above temperatures are maintained, which are from 5° to 10° higher than is generally advised. If the weather is dull for days at a time, a dewing once or twice a week will be sufficient. After the fruit is set another 5° may be added to the night and day temperature, and by this time disbudding will have to be attended to regularly. Rub the buds off gradually wherever they are pushing strongest, removing the fore-right shoots entirely, and such as are otherwise badly placed, but only pinching the heart out of those buds whose fruit is set, leaving one or two good leaves until the fruit is thinned or drops off. Thinning is commenced as soon as the fruit is about the size of a Pea, by removing all the smallest, and reducing the clusters of twos and threes to one. Before they begin stoning, they are thinned again to 3 inches or 4 inches apart on each shoot, and after stoning to about 9 inches, often less with Nectarines, though a foot is better when very large fruit is desired. After the fruit is stoned it swells fast, and the night temperature may be raised to from 65° to 70° at night, and to 85° or 90° with sun-heat; but it is safer to let it run up to 95° or 100° than admit heavy draughts of cold air, which are ruinous, and to compensate for the extra excitement by letting the thermometer sink to 50° or 55° at night. It is, however, important, at this stage particularly, that air be admitted, and in as great abundance as may be safe, in order to give colour and flavour to the fruit. Syringing should be discontinued as the fruit begins to ripen, but the trees must not be allowed, at this or any other period of their growth, to get dry at the root. In training, the chief thing is to see that every shoot has room, that every leaf is exposed to the light, and that the trees are allowed to grow without stint. If these directions are carried out, wood strong but not gross, and fruit buds plump and well developed, will be the result by June and July, when the fruit will be getting ripe generally. When it is seen that the fruit is about changing to the ripe state, the temperature should be reduced gradually, and when the fruit is gathered the lights should be removed off the house altogether, and turned to account in some other way till they are wanted again in November.

This completes the second year, by which time the trees will have covered a large surface. The third year the house may be started in December, just by shutting up the house and making the most of the sun-heat during the day, but no fire-heat should be applied till January, from which time the directions for the second year should be followed. But before concluding, just one word about airing, as it is understood. There is often much mischief done by the keen winds of March and April, and too much caution cannot be exercised at such times in opening the ventilators. To reduce the necessity of admitting too much air, therefore, an eye should be kept on the weather. If it is likely to be sunny or bright, the fire should be let down, in fact, pulled out at once, to cool the pipes, and the temperature allowed to go up above the usual figure, if it cannot be kept down without admitting great gusts of cold air. The house should also be shut up as early as possible, and syringed, and the temperature at night allowed to subside proportionately low. A high night temperature after a hot day cannot be justified on any grounds whatever in the early stages of forcing. J. S. W.

### RAISING VINES FROM EYES.

WITHIN these last two or three years this subject has been freely discussed in different horticultural periodicals, and by some of our most distinguished Grape growers; and I would refer more particularly to the articles written in

the *Gardener* for January and February, 1871, by Mr. Wm. Thomson (part of which appeared in *THE GARDEN*, p. 21), in which that veteran cultivator describes the system adopted by him with such successful results in raising the great quantities of Vines required to stock his vineries at Clovenfords. Having three vineries to plant last spring, I resolved to raise my own Vines and to try a modification of what I will term the Thomson or Simpson system, without the aid of pots. In the beginning of February we procured as many pieces of fresh turf as we thought would be required, cut about 8 inches square and 3 inches thick; the centres were scooped out and filled up with fine soil; in the middle of each a Vine eye was inserted surrounded with silver sand. In one of the vineries to be planted, we erected a temporary bed of tan on which the pieces of turf containing the Vine eyes were placed. After they had grown a few inches they were all moved, placed further apart, and set on slates, partly to prevent the roots from running down into the heating material, and partly to facilitate the removal of the Vines when wanted to be planted. When returned to their old quarters the spaces between the pieces of turf were filled up with fine soil, and a slight top-dressing was put over the whole. Into this the Vines rooted freely, and on the 16th of May they were planted into well-prepared borders, the roots being more like those of young Rose trees than Vines. Here they soon began to grow vigorously, every Vine going quite to the top of the house, a distance of 21 feet, and in some cases 6 or 7 feet down the back wall, making fine, short-jointed wood. They were allowed to carry all their laterals and to grow without restriction, so they completely clothed each roof. On the 12th of December, being six months from the time when they were planted, or a little over ten months from the time in which the eyes were placed in the pieces of turf, they were all cut back to about 6 feet from the ground, and averaged from 2 to 3 inches in circumference. On measuring a Vine in each house, I find the dimensions to be as follows:—

1st. Black Hamburgh, circumference at 18 inches from the ground, 2½ inches, or ½ short of 3 inches; length of wood made in the season, including laterals, 106 feet; 2nd. Muscat of Alexandria, circumference 2½ inches, length of wood 105 feet; 3rd. Lady Downes seedling, circumference 2½ inches, length of wood 161 feet. I am strongly of opinion that were we to pay more attention than we do to the preparation of Vines before we plant them, we should hear less than we do of sudden and, in some cases, unaccountable causes of failure. Nor need the practice of planting young healthy plants in preference to older ones be confined to Vines, for I consider that it is equally applicable in all cases of permanent planting, including that even of shrubs and Conifers. Within

a stone's throw of where I write I could point to Conifers planted five years ago, not more than 9 or 12 inches high, in close proximity to others then, 5 and 6 feet high, but now the small ones are quite equal to the large ones, and in some cases even considerably finer plants, thus showing the advantage of putting in in all cases well-prepared plants at first.

*Drinkstone Park, Burg St. Edmund's.*

W. NICHOL.

[Along with this communication came some remarkably fine shoots of Lady Downes seedling Muscat of Alexandria, and Black Hamburgh Grapes, all well ripened, hard, and firm, each shoot being as thick as one's thumb.]

VINES ON OPEN WALLS.

MAY I be permitted to plead the cause of that much-neglected fruit the Vine, and to advocate its more general cultivation on open walls? There is no fruit tree that suffers more when left to itself, or more liberally repays its owner for the care he bestows upon it

and the skill he exercises in its cultivation. Of the sorts adapted to this mode of treatment my experience extends to two only—the common Sweetwater, which every one knows, and the *Précose de Malingre*, which is not so well known as it ought to be. It is a small white Grape, oval in shape, and intensely sweet, though otherwise of indifferent flavour. But its great recommendation is its coming into leaf and ripening its fruit so much earlier than any other sort. In proof of this I need only mention the fact that in the present year the Grapes on this Vine were ripe at the end of September, and, though not so good as when the season has favoured them, they were not only fit to eat but agreeable to the palate; whereas the Sweetwaters were worthless, though they found favour with the blackbirds and sparrows, the only bipeds that seemed to think them worth the trouble of gathering. The *Précose de Malingre*,

cannot be preserved without the protection of muslin bags. Even this year it required them. The year before last, the first season in which I allowed it to carry a full crop, the wasps attacked the bunches even before they were ripe. The wall soon became a mass of yellow clusters. It seemed as if every nest in Rutland had sent its contingent to test the quality of the new Grape. Muslin bags were hastily constructed and applied, but even through some of these the wasps found their way. Here then is a Vine which will always produce a crop of ripe Grapes. Like other Vines, it can be made to fill its allotted space much faster than a fruit tree of any other sort, and can be trained along the slopes of roofs, and over outhouses and places inaccessible to wall trees of the orchard type. In such positions I find even the Sweetwater to produce excellent Grapes in good seasons, such as the summer of 1870 and the three that preceded it. Some degree of success may perhaps be attributed to the soil—the red soil as it is called in this part of England, which, though unfavourable to orchard fruits in general, seems to agree with the constitution of the Vine. Vine borders, however, are easily made, and it is always worth while to

A Mountain Fir. (See p. 73.)

improve and enrich the soil in which a profitable tree is growing; and good food is never thrown away upon the Vine. If every farm house had a properly cultivated Vine trained over the southern side, or even if every Vine now existing in such situations was properly cared for, there would be in ordinary seasons no deficiency of palatable outdoor Grapes in the midland and southern counties of England.—B. S.

**Oranges in Sicily.**—At a recent meeting of the Berlin Geographical Society, reported in *Ocean Highways*, Herr Langenbach read a paper on the culture of the Orange in Sicily. The Agrumè is first met with in latitude 41°, while the sweet Orange does not grow plentifully above 41°. The lecturer stated that there are seven different species of Sicilian Oranges, which are subdivided into no less than thirty-two different kinds. It is probable that the Arabs first introduced this fruit from Southern Asia; moreover, the Citrus medica, which appears to be the maternal fruit, is still to be found wild in parts of India. Sicily is peculiarly suited to the growth of the Orange, abounding as it does in clay and chalky soils, which are the most favourable to the tree. It has, nevertheless, much need of artificial irrigation to enable it to mature properly. Although Sicily was once the granary of Italy, it now produces only one-ninth of the cereal produce derived from the entire kingdom. But with regard to the Agrumè, Sicily is extremely rich, deriving as it does from that source a gross produce of 200,000,000 francs. The main misfortune of the country consists in the crowded state of its towns and the sparseness of its rural population.

**Orchard Pruning.**—What I should particularly recommend at the present time is immediate and decisive action as to the pruning and thinning of fruit trees. There is scarcely an orchard or garden that does not require severe overhauling in that respect, and the labour will be well bestowed. If the trees are of full size, get into the centre and at once clear away all the minor crossing and crowding branches, taking them away with a clean cut. That done, if necessary, thin out some of the principal branches, and leave the tree so that light and air can pass freely to every part. This will add materially to the strength of the branches retained, and the fruit, though numerically less, will be infinitely larger and of very superior quality. Some years back, when restoring a garden that had been left for upwards of twenty years to the tender mercies of a day labourer, I found some fine old Apple trees that had been left to nature for that time. From one grand specimen of the Blenheim Orange I cut as much wood as made twenty-five large faggots, and the following season I had the finest crop of the largest Apples of the kind I ever saw, not one of them being less than eight ounces in weight, and some of them more than a pound. All Apples might be increased in like proportion by the judicious pruning of the trees and the early thinning of the fruit.—P. A.

## NOTES AND QUESTIONS ON THE FRUIT GARDEN.

**Our First Apple Trees.**—The common or cultivated Apple tree was first introduced into England in the reign of Henry VIII., by Leonard Mascull, who planted it at Plumpton Place, near Lewes, Sussex. Some of the oldest cultivated Apple trees in England are to be found in the neighbourhood of Lewes, where the greater part of the trees are raised from cuttings.—C. RICHARDSON, *Gulstone, Surrey.*

**Orchard Labels.**—For a cheap durable label I do not find anything better than strips of tin, half an inch or more in width at one end and tapering nearly to a point at the other. The name is scratched on the broader end by an awl, the point of a file, or other hard point, so as to cut through the tin-coat into the iron. The name thus written becomes rusted where the point passes through, and renders the letters distinctly visible. The narrow end is passed once or twice around a branch, and holds the label, yielding as the branch grows.—CULTIVATOR.

**Peach Tree Protectors.**—Is 2 feet wide glass protection for a Peach wall sufficient, and do you think the protectors require to be made to open to admit rain to the trees? [2 feet wide of glass protection on the top of a Peach wall will be sufficient (if the wall is not very high), to save the crop in severe frosty springs. The great help of such a protection is that it keeps the blossoms dry, so that when frost occurs it does not injure them so much as if they were wet. There will be no occasion to open the protectors until all danger from frost is over, and the fruit set, when the trees after that will require all the advantages they can get from the summer rains.—W. T.]

**Low v. High Fruit Trees.**—An Illinois fruit grower, who has 12,000 Apples and from 4,000 to 6,000 Pear trees, finds that "those with low heads of the same varieties show at least two-thirds more fruit, as large or larger, and as highly coloured as those with high tops." To test the matter, he cut off in certain rows all the limbs from 4 to 6 feet from the ground, and in others encouraged the limbs to start close to the surface, and in the latter case neither thinned nor pruned, except occasionally to lop away a too lusty shoot, in order to preserve a symmetrical appearance or an evenly balanced head; and the above is the result.

**A Fruit Diet.**—A lazy dyspeptic was bewailing his own misfortune, and speaking with a friend on the latter's hearty appearance. "What do you do to make yourself so strong and healthy?" inquired the dyspeptic. "Live on fruit alone." "What kind of fruit?" "The fruit of industry; and I am never troubled with indigestion."

## THE KITCHEN GARDEN.

### REPORT ON KALES GROWN AT CHISWICK.

It is exactly ten years since the last trial of Kales was made in the garden of the Royal Horticultural Society. That was a very partial one in comparison with this upon which I am now about to report, the number of varieties being much less, and the various names under which the different varieties were received greatly more numerous. When I reported on the same subject in 1862, I was struck by the amazing confusion in which the Kales were found; and my surprise has not been lessened by the present trial. From the very much fuller character of this year's experiments, I have been enabled in many cases to add to, and in some to correct, those of 1862. This I have been enabled to do by the very prompt and liberal manner in which the members of the seed-trade have placed their collections at the disposition of the society. It is proper here to state that, although many errors in nomenclature are to be found in this report, apparently originating among the seedsmen, no blame is to be attributed to them, nor is there to be any impeachment of their good faith on that account; for this confusion of nomenclature has existed not only for years but for generations, and however anxious they may have been to correct it, the task was one most difficult of accomplishment. Now, however, that something like order has been attained, I trust that a more general concurrence in nomenclature will be maintained.

**Asparagus Kale.**—The original Asparagus Kale of a century and a half ago was a sprouting Broccoli, which was introduced from Italy. It received its name from the young shoots, terminated by a "button," bearing somewhat of a resemblance to the young shoots of Asparagus. In course of time the name gradually ceased to be identified with the Broccoli, and was applied to another variety of Kale also introduced from Italy, called Milan Kale, or Chou de Milan, which has the property of throwing up in the spring a profusion of long succulent shoots, which, when fully grown, resemble the shoots of Asparagus. But there are several other varieties of Kale to which the name is applied; and as there seems no uniformity on the subject, I shall quote the varieties which different seedsmen regard as Asparagus Kale. Messrs. Minier, Nash & Nash, are correct in supplying Milan Kale. Messrs. Fraser and Mr. B. S. Williams supply Buda Kale. Messrs. Beck & Co., Messrs. Carter, Messrs. Clark & Sons, and Mr. G. Gibbs supply Couve Tronchuda. Messrs. Wrench, Sutton, Lee, Nutting, and Mr. W. Paul, supply Siberian Kale; and it is to be remarked that, as all these varieties produce an abundance of succulents in spring, the name is not misapplied; still it would be as well if it were confined to one particular variety, and that this should be the Milan Kale.

**Buda Kale.**—This is one of those varieties that are called Asparagus Kale. It is very dwarf-growing, the stock being not more than 6 inches high, and very leafy. In this condition it remains all the winter; and in spring numerous long shoots are produced, some of which are from 2 to 2½ feet in length. The leaves are smooth and very much waved. There are three varieties of Buda—the green, the purple, and the lettuce-leaved or strap-leaved. There is no difference, except in colour, between the green and the purple varieties; but the lettuce-leaved is very distinct, the blade of the leaf being decurrent down the whole length of the footstalk, resembling in that respect the leaf of a Lettuce, or of Laing's Swedish Turnip. As regards utility and fertility there is no difference; and all are equally hardy. The Buda of Messrs. Minier, Nash and Nash, and of Messrs. Wrench, was true; that of Messrs. G. Gibbs, and of Messrs. Lee, was Siberian; and that of Messrs. A. Henderson & Co., was Couve Tronchuda. It was also received from the following sources perfectly true, under different names, thus:—From Messrs. Fraser and Mr. B. S. Williams the purple variety as Asparagus Kale. From Messrs. Carter and Wrench as Delaware. From Messrs. Wrench as Jerusalem. From A. Henderson & Cattell as purple Jerusalem. The green variety was sent by Mr. J. Grant as Lapland Kale, by Mr. Cattell as Egyptian, by Messrs. Sutton as new winter Kale, and by Messrs. Vilmorin, of Paris, as Chou à faucher. The lettuce-leaved variety was sent by Messrs. Clarke & Sons as Jerusalem Kale.

**Cottager's Kale.**—It seems to be generally agreed that the cottager's Kale is to preserve its undisputed individuality, as there were no instances, throughout the trial, of this excellent variety being received under any other name.

**Curled Kale.**—By far the most popular and most extensively cultivated of all the Kales are the curled or Scotch Kales, sometimes also called Curlies, German Greens, or Borecole. There are four distinct forms of the curled Kale—the dwarf and tall green curled, and the dwarf and tall purple curled. Those which are most generally cultivated are the green forms; and the great object of cultivators is to obtain these with the leaves as finely and as much

curled as possible; and in proportion as they are so, the more or less is the stock appreciated. Hence has arisen the great number of names under which they are sold. From Messrs. Drummond and Mr. Cattell, the green form was received as Prince of Wales, from Messrs. Clarke and Carter as Hearting Kale, from Messrs. Hurst as Cabbaging and Tall Curled, from Messrs. Sutton as Slater's New Cabbaging, from Messrs. Carter as Feathered Scotch and Abergeldi, from Messrs. Lawson as Superb Parsley Curled, Williams' Matchless, and Pontefract Green Curled, from Messrs. Stuart & Mein as Tynningham, from Mr. W. Paul as Jackson's Late Curled, from Messrs. Fisher, Holmes & Co. as Dwarf Green Curled Handsworth, from Messrs. Veitch as Veitch's Dwarf Late Curled, from Messrs. Minier, Nash & Nash, and Messrs. Beck, as Dwarf Green Curled Canada, from Messrs. F. & A. Dickson as Dickson's Imperial Dwarf Curled, and from Messrs. Barr & Sugden as New Moss Curled. All of these differed from each other only in the degrees of intensity with which the leaves were curled; and in this respect the New Moss Curled of Messrs. Barr & Sugden was remarkable. The Dwarf Purple form was sent by Messrs. Carter as Jerusalem Kale, and by Messrs. A. Henderson as Lapland; the Tall Purple from Messrs. Wrench as Brown Borecole.

**Jersey Kale.**—This is also called Cesarean Cow-cabbage, Tree-cabbage, and Jersey Borecole. It is a tall-growing plant, attaining the height of 4 or 5 feet, the stem clothed with long broad glaucous green leaves with long foot-stalks. In spring it throws out numerous long slender shoots, with which cattle are fed. It is never grown as a garden vegetable.

**Long Scotch Kale.**—This was received from Mr. W. Gorrie, of Edinburgh, as the true "Long Scotch Kale." It is the normal form of the wild Cabbage as it is found on the Dorsetshire coast. It was sent by Messrs. Vilmorin under the name of *Conve murciana*—and by Messrs. Sutton of Buckman's hardy winter Greens.

**Marrow Kale.**—This is the *Chou moellier* of the French, a form of the Jersey Kale which produces a long thickly swollen stem like a gigantic cigar, the swollen part being filled with a mass of tender pith. There are three varieties of the Marrow Kale, distinguished as the *white*, the *purple*, and the *small*. The white grows from 4 to 4½ feet high, the stem being smallest at both ends and thickest in the middle, where it is about a foot in circumference in the largest specimens.

**Milan Kale.**—The name by which this is often called is *Chou de Milan*. It is unfortunate that it is so; for *Chou de Milan* is the name given by the French to Savoys. Except that they both belong to the same genus, there is no resemblance whatever between the Milan Kale and a Savoy. The Milan Kale produces a stock from 18 inches to 2 feet high, clothed with plane bluntly-toothed leaves, and terminated by a close rosette of leaves forming a small incipient head. In spring it throws out a large quantity of fine succulent shoots, which, when cooked, form one of the most delicious dishes of the winter-green class; and it is from this circumstance that the plant has been called Asparagus Kale. From Messrs. Beck & Co., G. Gibbs, Nutting, Minier, Nash, & Nash, and Mr. Cooper, it was received perfectly true under the correct name. There is a purple variety received from Messrs. Vilmorin under the name of Flanders Purple.

**Palm Kale.**—The stem is 2 feet to 2½ feet high, clothed with large oblong obovate leaves, the blade of which is decurrent the whole length of the footstalk, of a dark green colour, which curve gracefully upwards and outwards, giving the plant the aspect of a miniature Palm. In the spring it throws out a profusion of long slender shoots, which are of no value as a vegetable. After these shoots are produced, the plant entirely loses its ornamental character. It was received from Messrs. Vilmorin under the name of *Chou Palmier*.

**Ragged Jack.**—Like the Cottager's Kale this seems to have few synonyms. Its character is sufficiently distinct to render it easy of identification, being a very dwarf variety with a stock not more than 4 to 6 inches high, and leaves which are deeply lacinated, the segments being trifid or multifid. It is generally of purple colour, and occasionally green. In the spring it produces a great quantity of tender shoots, which are much esteemed as a vegetable. It was received from Mr. B. S. Williams as Camberwell Borecole.

**Siberian Kale.**—This is one of the hardiest and one of the best of all the sprouting Kales. It is also very distinct, and can never be confounded with any other variety. The stock is very dwarf, being only 4 to 6 inches high. The foliage is always green. The leaves are sinuated, coarsely serrated, and plaited on the margin. In spring it produces a large crop of tender shoots, from a foot to 15 inches in length. This is one of the varieties the nomenclature of which is very confused. From Mr. B. S. Williams it was received quite true as "Siberian" or Lapland; from Messrs. Wrench, Sutton,

William Paul, Leo, and Nutting, it was received under the name of Asparagus Kale, from Mr. G. Gibbs as Buda Kale, from Messrs. Nutting, A. Henderson, Cattell and Drummond, as Delaware, from Messrs. Minier, Nash & Nash, Sutton, G. Gibbs, Lee, Carter, and Cooper, as Jerusalem, from Messrs. Carter as Acme, and from Mr. Cattell as Curled Jerusalem.

**Woburn Kale.**—This closely resembles the wild Cabbage, and long Scotch Kale; but it appears to be of a more perennial character. It may be propagated by cuttings, as, indeed, all the other varieties may; but it is more woody and shrub-like in its growth. It is not worth cultivating, except in very northern and exposed situations, as it is very hardy, and will stand more rigorous winters than perhaps any of the other varieties.—*Proceedings Roy. Hort. Soc.*

**Broccoli Culture.**—Broccoli in some shape, and Mushrooms in plenty, are two things indispensable at Burghley. Just now we have a good stock of Walcheren, well covered with Fern—the best of all protections for outside things, followed by Snow's Broccoli, also covered up. For my first crop of Walcheren I sow the seed about the middle of August, and plant (under handlights) the first week in October all the large plants, reserving the small ones for three-light boxes, which give me a succession from the first week in June until the last in July. These are followed by a pinch of seed sown inside in February, which comes into use in August. In March we make a sowing on a south border, and another the first week in May; and by picking out all the best plants first, leaving the smaller fry for the last batch, we are enabled to keep well on until Christmas. The land cannot be too highly tilled for Cauliflower, trenching and manuring being the order of the day; but for spring Broccoli the case is different. We want good stocky plants. They are the following crop after the early Potatoes are cleared, and the firmer the land the better. We strike the lines 3 feet apart, and plant 2 feet 6 inches apart in the row, one man making the holes with a crowbar, and another dropping in the plants. The only planting required is to well wash the dry earth into the holes, filling them level with the ground; and they seldom require any more water. We never lift or lay in our Broccoli, the plants being sturdy and hardy, but in severe weather we cover the whole with Fern, the wind, rain, &c., washing them down to the fatal spot—the neck, and thus preserving them. The following varieties keep us supplied with Broccoli nearly the whole year round:—Snow's Winter White; Osborne's, a real good thing; Early Malta; Frogmore Improved; for early spring, say January to April, when we have Eltester's White Protecting, Hibbe's Royal Alfred; and for latest of all, Cattell's Eclipse, the best of all Broccolis for late work.—*R. Gilbert, in Florist and Pomologist.*

NOTES AND QUESTIONS ON THE KITCHEN GARDEN.

**Sutton's Red-skinned Flourball Potato.**—Several correspondents write in praise of this Potato as being free from disease, and in every way of fine quality.

**Horseradish.**—It may not be generally known, that by placing leaves or litter on the tops of Horseradish crowns 2 feet or so thick, the plants grow through them in the course of the summer, making small white roots the thickness of one's finger, which are as tender as spring Radishes, and a great step in advance of the tough stringy stuff usually supplied with our roast beef.—*R. GILBERT.*

**Salad Culture.**—On examining some salads in a market garden a short time ago, we were struck by the difference which existed between different squares in which they were planted. Some had the appearance of having been sown long before the others, and of having been better tended, but such had not been the case, the increased vigour being simply due to a slight coating of old tan, with which the soil was covered. Where the soil had been covered with straw, the plants were not nearly so fine as where the tan was used.—*Rene Horticole.*

**Mushroom Spawn.**—The best spawn I ever used was some that had been kept above a warm and dry place for two years or more. It became as hard as a board, and had to be broken up with a hammer when wanted for spawning the beds. I find also, that spawn kept in this way produces Mushrooms sooner than under ordinary circumstances. I have seen the Mushrooms up in four weeks from the date of spawning, and have gathered plants in six weeks—about the period, it is generally supposed, that spawn requires to run. Many Mushroom growers make a mistake in spawning their beds at too low a temperature, say at 75°. This temperature will do, but a temperature of 85° is perfectly safe, will cause the spawn to run sooner, and will give quicker returns.—*J. S.*

## THE GARDEN IN THE HOUSE.

### ILLUMINATION OF DINNER TABLES.

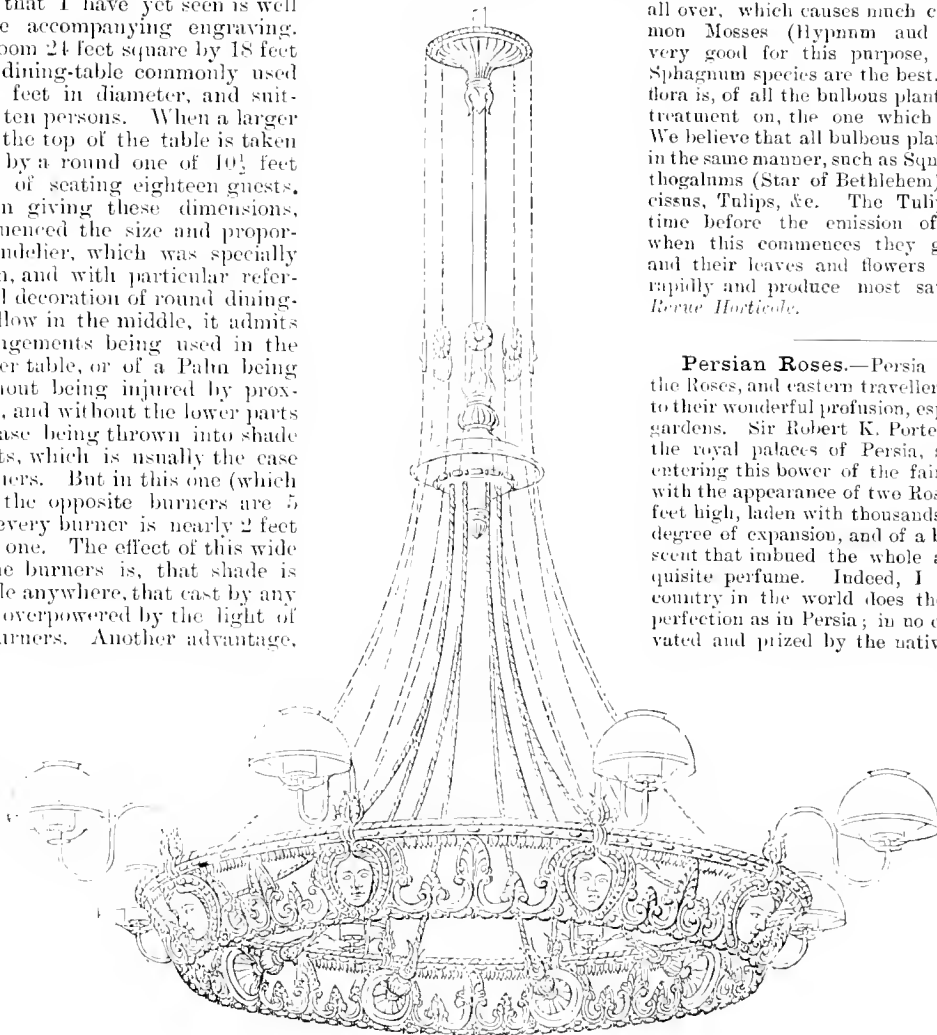

WHERE flowers are much used for decorating dining tables, it is important that there should be some fixed and suitable means of lighting the room. For this purpose there is nothing more convenient than gaslights, provided that the gas is of good quality and the room is well ventilated. Assuming that these conditions have been secured, the position or distribution of the lights next demands consideration, and is a matter worthy of more attention than is commonly bestowed upon it. It is too often the case that chandeliers, for instance, are chosen more for the beauty of their appearance by daylight than for their provisos after dark. The best chandelier for a dining-room that I have yet seen is well illustrated in the accompanying engraving. It is put up in a room 24 feet square by 18 feet high, where the dining-table commonly used is a round one, 7 feet in diameter, and suitable for eight to ten persons. When a larger party is expected, the top of the table is taken off and replaced by a round one of 10½ feet diameter, capable of seating eighteen guests. I am particular in giving these dimensions, because they influenced the size and proportions of this chandelier, which was specially made for the room, and with particular reference to the floral decoration of round dining-tables. Being hollow in the middle, it admits of very tall arrangements being used in the centre of the larger table, or of a Palm being placed there, without being injured by proximity to a gas-jet, and without the lower parts of the plant or vase being thrown into shade by the upper parts, which is usually the case with most chandeliers. But in this one (which has eight lights) the opposite burners are 5 feet apart, while every burner is nearly 2 feet off from the next one. The effect of this wide distribution of the burners is, that shade is scarcely perceptible anywhere, that cast by any one burner being overpowered by the light of the other seven burners. Another advantage, and a very important one, of placing the lights so far apart from each other, is that the illumination of the table and its decorations is less glaring and more evenly distributed, not only over the table, but also over the whole room.

### THE TRITELEIA UNIFLORA IN MOSS.

TOWARDS the end of last February it was remarkable to see at 20, Quai de la Mégisserie, Paris, handsome saucers filled with fresh mosses or turf of a beautiful bright green, on which shone the elegant colours of the flowers of *Triteleia uniflora*, a pretty Liliaceous plant of Texas, which is well known, and which is largely cultivated for its pretty blossoms. It is, however, the first time we have heard of its being cultivated in this manner, so we think it may be useful to give a few instructions on the means employed to obtain these results. The best time for planting the bulbs of the *Triteleia* in moss is November or December, but they will succeed if planted early in January. The manner of planting is as simple as possible. Take some pieces of common Moss in its natural state; if too dry it must be wetted, and then fill the plates or saucers destined for this pretty plant. The bulbs are simply

placed on a little heap of moss or turf, and care is taken to have a certain quantity of water in the saucers thus prepared, but which in any case must not exceed half the depth of the saucer. When the bulbs are placed the saucers must be put in some dark spot, the same as is generally done when bulbous plants are cultivated in vases or bottles. A cellar or cupboard are good positions. Darkness and also a temperature a little elevated, and above all damp and regular, are conditions propitious to the emission of the roots. When these are sufficiently numerous and developed the saucers are taken to a very light place (where the frost cannot touch them). The *Triteleias* thus treated flower about three months after the bulbs are planted. These ornamental saucers can be made even prettier, by sowing some seeds of fine grasses; but they ought to be sown at least six weeks or two months after the bulbs are planted. A simple border of these round the saucer is more elegant than the result of seeds of the same kind sown all over, which causes much confusion. The common Mosses (*Hypnum* and similar kinds) are very good for this purpose, but those of the *Sphagnum* species are the best. The *Triteleia uniflora* is, of all the bulbous plants we have tried this treatment on, the one which springs up soonest. We believe that all bulbous plants can be cultivated in the same manner, such as Squills, Hyacinths, *Ornithogalums* (Star of Bethlehem), Persian Iris, *Narcissus*, Tulips, &c. The Tulips remain for some time before the emission of their roots; but when this commences they grow very quickly, and their leaves and flowers develop themselves rapidly and produce most satisfactory results.—*Revue Horticole*.

**Persian Roses.**—Persia is the very home of the Roses, and eastern travellers have often referred to their wonderful profusion, especially in cultivated gardens. Sir Robert K. Porter, speaking of one of the royal palaces of Persia, says: "On my first entering this bower of the fairy-land, I was struck with the appearance of two Rose trees, full fourteen feet high, laden with thousands of flowers, in every degree of expansion, and of a bloom and delicacy of scent that imbued the whole atmosphere with exquisite perfume. Indeed, I believe that in no country in the world does the Rose grow in such perfection as in Persia; in no country is it so cultivated and prized by the natives. Their gardens

and courts are crowded by its plants, their rooms ornamented with vases filled with its gathered bunches, and every bath strewn with the full-blown flowers plucked from the ever-replenished stems. . . . But in this delicious garden of Negaaristan, the eye and the smell are not the only senses regaled by the presence of

the Rose. The ear is enchanted by the wild and beautiful notes of multitudes of nightingales, whose warbling seem to increase in melody and softness with the unfolding of their favourite flowers. Here, indeed, the stranger is powerfully reminded that he is in the genuine country of the nightingale and the Rose." Sir William Onseley accompanied his brother, the ambassador, on a visit to a man of high rank, at Teheran, and though there was a great profusion of meat and fruits at this entertainment, "it might," he says, "have been stiled the feast of Roses, for the floor of the great hall, or open-fronted *talar* was spread in the middle, and in the recess, with Roses, forming the figures of cypress-trees. Roses decorated all the candlesticks, which also were quite numerous. The surface of the *hamb*, or reservoir of water, was completely covered with Rose-leaves, which were scattered on the principal walks leading to the mansion. The surface of the reservoir was so entirely covered

with Rose-leaves that the water was visible only when stirred by the air, and by the servants, during the entertainment, continually scattering fresh Roses both upon the water and the floor of the hall."

## THE HOUSEHOLD.

### CABBAGE.

THE Cabbage is in many houses a forbidden dish, because the odours which arise from its cooking are so obnoxious, but if these directions are followed, there will not be much if any complaint: Quarter the Cabbage the night before it is required, and remove the hard stalk; wash it well, and cut into small pieces. Next morning change the water, and when ready to cook, skim out the Cabbage into a large pot of boiling water, with a small teaspoonful of saleratus added to it. Boil steadily for forty or fifty minutes, but take care that the water does not boil over upon the range or cooking stove, for this is one of the chief causes of the very disagreeable odour which fills the house. If you are cooking corned beef at the same time, after skimming it thoroughly you can add a pint of the liquor in which it is boiling to the Cabbage, as some like the meaty flavour, and if there is no beef liquor at hand, a piece of beef suet will answer the purpose; but Cabbage should never be boiled in the same vessel with salted meat, as it spoils the flavour of both. When the Cabbage is so well boiled that it will easily mash with a knife skim it out into a colander, and press out all the water, and season it with butter, salt and pepper. Prepared in this way, Cabbage really becomes an inviting dish, and is a very healthy one. It is because it has so often been badly cooked, that it has fallen into disrepute. If you prefer to have the Cabbage more in shape, it can only be halved, and the hard stalk cut out; then tie it up in a piece of coarse muslin, and boil for one hour, always putting it into boiling water at first.—*Cultivator.*

**A New Process of Preserving Fruit.**—A description is given in an American paper of one of the evaporators in New Jersey, where fruit and vegetables of every description are preserved by the Alden process. Three hundred bushels of Apples are just now being run through the mill each and every day, and Peaches, Plums, Grapes, &c., came in for their share of notice in their respective seasons. In the vicinity of the works cars were loading, and there was all around swift movement, indicative of business enterprise. Orders from Government at present occupy attention. The point is, that a soldier going out to fight the Indians can carry in his pocket evaporated vegetables and fruit enough to last him a month or more. By this excellent process it is rendered possible and profitable to save crops, however large they may be, and however low the prices. Before such processes were invented, in plentiful years the fruit used to go to the pigs.

**Champignons Farces.**—This delicious dish, known to all cooks in France, is easily prepared and much relished. Take Mushrooms, large or small, according to taste; wash, but do not soak them; dry them well, and finally skin them. Cut off and mince the stalks, and add a quarter of the quantity of chopped Parsley and the same of Shallots, also chopped fine; dry the mince by squeezing it in a clean cloth, and cook it for five minutes with butter melted with a little stock, or *bouillon*; when the sauce is done, pour it over the Mushrooms laid in a buttered tin or plate, and place them in an oven or Dutch oven, for about ten minutes. The delicacy of this and many other dishes depends upon whether the cook knows how to make sauce; the best mode in this case being that which is called *roux* in the French *cuisine*, which is as follows:—Melt fresh butter in a small saucepan, and stir in two-thirds of its own weight of fine flour; when completely mixed, let the saucepan stand for at least an hour, in hot cinders, stirring the butter occasionally with a wooden spoon; if for brown sauces let it stand two hours, instead of one, on the cinders. The *roux* may be used immediately or put away in a covered pipkin, slightly buttered for future occasions. Butter thus melted blends agreeably with all sauces, and forms a delightful contrast to the pasty stuff often served for melted butter.

**Cocoanut Pudding.**—Soak for two hours in a pint and a half of milk a tea-cupful of fine bread-crumbs and the grated meat of a cocoanut, then add the well-beaten yolks and whites of six eggs, a tea-cupful of sugar, the grated rind of a lemon, and a pint and a half of milk. Stir well together and bake in a hot oven. Like all other custards, this must not be allowed to remain in the oven long enough to become watery.

**A New Winter Salad.**—Ordinary Buckwheat, such as we give to fowls, grown in a moderately warm greenhouse, and cut like Mustard when about 2 or 3 inches high, makes a delicious winter salad, a combination of Lettuce and Corn-salad in flavour. It can be grown in pans all the year round without the least trouble, and even when Lettuces are plentiful will be found a very desirable addition to the salad bowl.—W. H. CULLINGFORD, *Kennington.*

## WORK FOR THE WEEK.

### PRIVATE GARDENS.

**Flower Garden.**—Plants of *Berberis Darwinii* and *Aquifolium* form lovely objects just now, both in the front of shrub-beries and as isolated specimens on lawns. Amongst dwarf-growing plants, few can at present equal some of our hardy Heaths, which are very effective; but should there be in any case a lack of flowers, the deficiency may be made up if plants of Daisies, Aconites, Arabis, Saxifrages, Alyssums, Pansies, &c., are lifted with good roots from the reserve ground, and transplanted to where they are required to bloom. Indeed Daisies may be lifted with good balls before winter sets in, and placed in lines about six inches apart in a bed of ashes, purposely for spring transplanting. Aconites grown in pots until they come into flower can be transferred to the open ground, to make up vacancies or to supply colour. If roots of Fennel plants were placed as centres in beds as soon as the summer bedding plants were removed, they will now be producing most beautiful foliage, and among such plants none are so effective as *F. gigantea*, but *tingitana* and *glauca* may also be used for the same purpose. Poly-antheses and Primroses of various kinds, even although in bloom, may be shifted to where they are most required. On some kinds of herbaceous plants the old flower-stems should be left, unless they are growing in prominent positions, as the dead spray is of importance in protecting the crowns of the plants from frost. This is particularly requisite this season, as some of the plants have already begun to grow. The hardier sorts of herbaceous plants may be lifted, divided, and replanted. Periwinkles should now be lifted, and transplanted under the shade of trees; *St. John's Wort* and *Irish Ivy* are also plants admirably suited for such work, and will grow and flourish where grass will not thrive. Place some sifted ashes around the necks of plants likely to suffer from frost. Keep the crowns of *Funkias* well protected with leaves, cocoanut fibre, or ashes. Be prepared for protecting plants in borders, and shrubs and climbers on walls. Do not prune any shrubs that are comparatively tender until warmer weather sets in, for they are too far advanced already, and pruning would only assist further progress, as well as liability to injury from frost. Hardy deciduous shrubs may, however, still be pruned.

**Conservatories.**—Before growth begins afresh in the case of greenhouse climbers, let them be pruned and thinned, so that the young shoots may break away strongly. Specimen Heaths, *Chorozemas*, *Brachysemas*, and some other plants are advancing too hurriedly, *i.e.*, if intended for the purposes of exhibition; therefore remove them from their present quarters to houses having a north or east aspect, or, in the absence of these, to the coolest part of the conservatory. Those that are not to be repotted this season should be properly staked; any that are shifted, however, should have all old stakes taken out and replaced by fresh ones, and if any of the present ones be used they must be repointed. Shift *Calcceolarias* and *Cinerarias* when necessary. Sow, if not already done, some *Cyclamen* seeds. Start a few *Fuchsias* into growth for spring and early summer blooming. Put in any *Chrysanthemum* cuttings that may be required; if sufficient stock has been obtained, transfer the old plants to the open border. Examine all soft-wooded plants, and remove decaying portions. Keep show and fancy *Pelargoniums* near the glass in cool airy houses. All evergreen plants, especially *Azaleas*, should be gone over occasionally, and should have all decaying leaves removed from them. Maintain a good succession of blooming plants from the forcing pits, and continue to introduce according to the demand and convenience another supply to take their place. Syringing twice a-day assists the bursting into growth of the buds of shrubs, and a hasty formation and development of their flowers. Hyacinths, even under the coolest possible treatment, have already pushed up their leaves, which are 2 inches above the pots, and their flower-spikes are formed. To ensure success, transfer them from their outdoor plunging material to a moderately cool pit. Arrange them on the side shelves, admit air freely, and keep them comparatively dark by shading thickly with mats.

**Stoves.**—*Allamandas*, *Dipladenias*, *Stephanotis*, *Bougainvilleas*, and *Clerodendrons* (climbing ones) should be cut back at once if not already done, and repotted as soon as convenient, but not encouraged to make growth. Keep the soil pretty dry even after potting, insert the principal stakes, and preserve the young growths from getting broken. Plants of *Poinsettias* and *Euphorbia jacquiniæflora* done blooming should be stored away on back shelves under the stages, or in any other place where they can be kept dry in an intermediate house or coolest end of the stove. *Aphelandras* done flowering may be treated in the same way. Do not allow any young plants to suffer from want of root room, but give them a shift as soon as they require it. Of stove bulbous plants at rest start a few into growth,

and keep those already breaking into leaf in a nice growing temperature. Syringe daily and maintain a high temperature in the Gardenia house where the plants are late in coming into bloom.

**Orchids.**—From amongst these the warmest nooks in our conservatories are being supplied with their most showy flowers. Oncidiums, Odontoglossums, and Cologynes are in great beauty, and these, together with Phalaenopsids, furnish masses of white flowers, orange and crimson and allied colours being furnished by Masdevallias, Adas, Sophronitis, Epidendrums, Barkerias, &c., whilst Cattleyas, Vandas, Saccolabiums, Laelias, Dendrobiums, Phajus, Restrepias, &c., afford an immense variety of both colour and form. Prepare materials for a general potting next month and the succeeding one. Begin to pot as soon as practicable Odontoglossums, Miltonias, Masdevallias, &c., and those not requiring this at present should be top-dressed. Any *Calanthes* not yet placed at rest should be laid on their sides and kept dry. As soon as any appearance of growth presents itself in the earliest rested plants, repot them and place them under growing conditions. Keep *Pleiones* in a nice growing state; any of the varieties that have not finished blooming should be repotted as soon as their last flowers are past. Maintain a moderately moist atmosphere in all the Orchid houses, otherwise *Phalaenopsids* and other long aerial rooted species will suffer.

**Indoor Fruit and Forcing Department.**—Pine plants intended for starting next month should have the temperature increased a little, but no extra watering should be given to the roots. Supply those throwing up and those swelling fruit with both atmospheric and root moisture. Do not disbud Peach and Nectarine trees too much at first, but syringe daily all trees started into growth, before or after flowering; but do not, under any circumstances, apply the syringe to trees in flower at this season. For Cherries, heat produced from fermenting material is most congenial to their wants; and their roots, when plunged in it, are greatly benefited by a little extra heat. Top-dress the pots with good loam and thoroughly decayed manure. The *May Duke* is a useful sort for early forcing. Maintain a brisk temperature in Vineries where the plants are in bloom. Stop, thin, and remove shoots as required. Attend to timely thinning of the berries, moisture, and proper temperature. Muscats in bloom require 5° higher temperature than *Hamburghs*. Strawberries required to throw up their flower-spikes should be kept rather dry for a short time, to induce them to do so, but water freely after the fruit has set. Keep up successional supplies of Rhubarb, Seakale, Asparagus, Dandelions, Lettuces, Endive, Chicory, Chives, Tarragon, Mint, small salads, young Onions, Carrots, Radishes, &c. For these prepare hot-beds, and utilise any already put up.

**Hardy Fruit and Kitchen Garden Department.**—Proceed with the pruning and nailing of wall trees, such as Plums, Pears, Cherries, and Apricots; and all standards, if not already done, should be pruned as expeditiously as possible. Moss growing on the stems of old trees should be scrubbed off, and afterwards the trees and large branches should be washed with a mixture of lime-water, soot, and brine. Root-prune over-vigorous trees, taking care not to encroach too severely on the roots. Cut off shoots to be used as scions in grafting, and insert their ends in soil in some well-sheltered situation. Head back stocks, for if allowed to remain without being cut until the sap is in active circulation, the bark commonly dies back a little below the wound. Freely expose Lettuces, Cauliflowers, &c. in frames in favourable weather, protecting them from frost at night. Plant in dry ground Ash-leaf Kidney Potatoes, and make new plantations of Horseradish and Jerusalem Artichokes. Sow some Parsley on a sheltered spot, also some of Wood's Frame Radishes on a south wall border; Early Horn Carrots may be treated the same as Radishes. Some Early Dutch Turnips may likewise be sown on a warm border. Avoid sowing anything on sodden soils, as much harm is done by so doing, and whole crops frequently lost.

#### NURSERIES.

**Indoor Department.**—The grafting of Tea, Noisette, and other Roses should now be proceeded with, using the *Manetti* stock for the purpose. Side or cleft grafting is the best method, and for this purpose the stocks should be established in 60-sized pots and decapitated previously to the scions being affixed. Tie them on with worsted, over which put a covering, consisting of pitch with a little bees' wax, and a piece of a tallow candle mixed with it. If the pots containing the plants are plunged in cocoa-nut fibre, and have a moderate bottom heat, and a temperature of from 55 to 65 be applied, the result will be satisfactory. Permit shoots to spring from the stocks unrestricted until the scions have formed leaves sufficiently strong to elaborate the sap, when all shoots from the *Manetti* should be rubbed off and in future kept from appearing.

Take indoors *Rhododendrons* for grafting purposes, and lift a few more from the open ground, which should be potted into 4 or 6 inch pots for autumn grafting. *Rhododendrons*, however, like most other plants, thrive best when grafted in spring. The grafting of *Camellias* should now be proceeded with; but in their case, as in that of evergreen plants in general, do not cut them over like *Roses*; on the contrary, affix the scions to the sides of the shoots or stem by removing a small piece of the bark and wood, cutting downwards; and at the base of this longitudinal cut, leave a niche to prevent the scion from slipping down; then tie the scion firmly in its place with a piece of matting, worsted, or other soft material. Autumn-grafted *Ivies* may now be turned out into cold frames, or plunged amongst cocoa-nut fibre at the bottom of a north wall. Do not remove the tops of the plants yet, because the scions have not sufficiently attached themselves to be able to properly utilise the sap. The spring grafting of *Ivies* may now be begun if a little start is given to the plants. Young Oak stocks potted in sixty-sized pots may be kept under the stages of a cool pit if not liable to drip, and the finer kinds grafted on them after they have started into growth. Graft now all the finer kinds of *Daphnes*, using *D. pontica* or *D. Mezereum* for stocks. *Daphnes* require to be kept in close frames in an intermediate house. Autumn grafted *Hollies* may be removed from the pits to sheltered positions out of doors and treated like *Ivies*. Autumn inserted cuttings of various kinds of Conifers, *Euonymuses*, *Euryas*, *Hollies*, &c., should still be kept rather close and in very gently heated pits. Do not interfere with Japanese Maples that were layered in pots sunk in beds indoors in autumn until after active growth has commenced, for then they form most of their roots, an operation in which they are aided by being left adhering to their parents. Any time throughout the early summer they may be partially, and in a few weeks afterwards, wholly severed from their parent stocks, so that the latter may have sufficient time to perfect and ripen their young wood, which may be sufficiently layered early in autumn. Cuttings of Box, the common kinds of *Ivies*, Portugal Laurels, Bays, *Laurustinuses*, and many others inserted in autumn under handlights in well sheltered corners, or between hedges, should have the protection of a mat in cold nights. If the handlights are made so as afford ventilation at top, there will be no necessity for tilting up the lights at any time during the winter.

**Outdoor Department.**—The ground between rows of Conifers not intended to be removed this spring should be dug over, but not so as to injure the roots. Chickweed and other pests of that kind have grown so freely this winter that a rough weeding is necessary before digging, otherwise the overturning of the soil simply means transplanting the weeds. When the layers of deciduous plants, such as Limes, Planes, Poplars, Cornuses, &c., are sufficiently rooted they should be removed and transplanted, so as to permit of the ground being dug, and last year's wood being layered a little later in the season. Insert cuttings of deciduous trees and shrubs in sheltered places, such as in narrow borders, at the base of walls or hedges, in rows 6 inches apart, and an inch or thereabout between the cuttings, which should consist of last year's wood cut into pieces from 6 to 9 inches long. Lime, Poplars, Elders, Weigelas, Spireas, such as *prunifolia*, Ribes, *Dentzias*, Cornuses, Buddlens, deciduous Magnolias, *Viburnums*, *Jasminums*, such as *nudiflorum*, Willows, and many other plants, may be increased from cuttings inserted in this way, between January and March. Retain the covering of Birch branches and other material laid over beds of seedling *Rhododendrons*, *Arbutuses*, *Cotoncasters*, &c.; and should hard frost come give some additional covering if necessary. Transplant Conifers of various ages, but not so thickly as to touch one another in the rows.

#### MARKET GARDENS.

Continue the manuring and digging of such ground as can be worked; towards the east and south-east of London, however, many fields are yet flooded some feet in depth, particularly between Stratford and Lea Bridge, where little is to be seen but water, not only obstructing outdoor garden operations, but also rendering roads almost impassable. The third Radish crop now being in the ground bird scaring is necessary, both on account of it and the second crop; the first is too far advanced to suffer from these pests. Keep if possible all Radish plantations near one another. Transplant any Cabbage plants that may yet remain unplanted. Preserve some of the finest plants of Brussels Sprouts for seed, also Savoys, Sprouting Broccoli, and Coleworts; remove them from the main plantation to some spare spot, and keep every kind together, for when apart they are apt to get crossed through the insect agency. Make a sowing of Spinaeh. Get ground in readiness for early Potatoes, and have some forethought as regards the Onion crop, which should be sown next month. Lift layers of Moss Roses, and transplant them in lines 15 or 18 inches apart.

## THE GARDEN.

—o—o—o—  
 "This is an art

Which does mend nature : change it rather : but  
 THE ART ITSELF IS NATURE."—*Shakespeare.*

### THE SEASON.

FROST now seems likely to take the place of the abundant rains which have induced such an unusually early bloom in our gardens, as well as encouraged the late growths of the past year. The probability is that our gardens are likely to suffer much during the coming few weeks, and a few words as to the best course to pursue in the presence of such danger may not be without use. It will be wise to see to the thorough protection of any favourite specimens that are known to be at all tender. Even "protection" that merely shades the plant from the sun often saves its life. Camellias, and many tender plants, will survive upon the north side of a wall or fence, although they would perish if exposed to the sun on the southern side. If mats or other covering cannot be spared, take some Fern or straw and shake it thinly over the plants; or, what will do equally well and be more sightly in dressed ground, go to the woods and cut branches of Spruce, Scotch, or other Fir trees, and place them so as to shade and protect the plants. A sudden thaw, with full exposure, will split the bark of a tree in all directions. Shade the plant, allow it to thaw gradually, and little or no injury will be done. Just the same is it in the greenhouse. If the plants are frozen, shade them; apply fire-heat, and directly the temperature of the house is raised above the freezing point, syringe the plants gently with cold water until such time as they are quite thawed. Some adopt the practice of thawing with warm water, and the plants are immediately destroyed. Several years back, when we had more than 20° of frost for several nights in succession, we had a quantity of Calceolarias in a Vinery to which we could not apply any heat. They were frozen as hard as stones, and some thought irretrievably destroyed. We had them laid on their sides upon the frozen ground, covered with some old doors, and then some straw. A week after the thaw came they were uncovered, and proved to be as fresh and healthy as if they had never been exposed to frost at all. When tender plants are frozen, no better rule can be followed than to keep them closely covered up until they are thawed. Let there be no deviation from this rule, and little injury will be sustained. With kitchen garden crops much the same rule must be followed—shade and shelter. The other day we walked through the fine kitchen garden of the Marquis of Exeter, at Burghley. No man grows vegetables better than Mr. Gilbert, the intelligent gardener there; and we found the whole of his crops—Cauliflower, Broccoli, Brussels Sprouts, Savoys, Celery, Parsley, &c., covered over with a thin sprinkle of dry Fern or Bracken, as it is commonly called. In this manner Mr. Gilbert assured us he generally succeeded in securing his crops, and hoped to do so this season. These general hints will show what it is best to do at the present time. We fear many will find their Potato and other root stores under the icy embrace of frost. If so, they cannot possibly do better than cover thickly with dry straw or litter of some kind, so that when the thaw comes it may act as gradually as possible. After Murphy's winter, when, on January 1, 1838, at four o'clock in the morning, we saw the thermometer standing at 8° below zero, or 10° of frost, we picked up from among the leaves of a Strawberry bed an Apple and a Potato both perfectly sound, though they had been exposed to such intense cold. The Potato was planted and produced a crop; the Apple, after being kept for some weeks as a curiosity, was eaten and found to be of fair flavour. This is a sufficient illustration of the advantage of shade, darkness, and slow thawing. We are not prepared to say that either Apples or Potatoes will be so good after as before they were frozen, but this we may say they will be still eatable, and that will be something saved. If fruit is frozen we cannot do better than cover it down and allow it to thaw gradually; any attempt to thaw it by artificial heat must end in failure. In gathering green vegetables for use in frosty weather the best plan is to gather

them two or three days before they are wanted for use, and, placing them in cold water, let them remain in it until they are wanted for use. We fear the frost will play sad havoc with the Roses, especially the Tea and Bourbon classes; here, too, shade and shelter will be found of great service, and some Bracken or straw worked among the branches, and then enveloped in straw, or still better, some water-proof material, such as oiled calico, will be found an immense protection. If such protection be applied before the frost sets in severely, the risk of injury will be considerably reduced. We need scarcely repeat that such things as early Rhododendrons of the scarlet section, and various Conifers, of questionable hardiness, will be the better for shade and shelter. One fact more: when the frost goes, do not be in a hurry about pruning your plants, to make them look tidy; leave them until the sap begins to move, and then you will see better where and how to cut. A.

### LORANTHUS EUROPEUS AT GLASNEVIN.

DR. MOORE has succeeded in growing this curious plant for the first time in Britain, and reports on it as follows to the Royal Dublin Society:—

To introduce the European Loranthus to Oak trees in the British Islands has long been an important desideratum among botanists, horticulturists, and amateurs. It has, to our knowledge, been tried on several occasions without success; and, so far as we are aware, there is no instance on record of this singular parasitical plant having been seen in a growing state in Britain or Ireland, until we have at last got it established at Glasnevin. To afford those who are not acquainted with this plant some idea of its nature and habits, I shall liken it to the Mistletoe, *Viscum album*, of which most of us know something. This and the Loranthus belong to the same natural order of plants, and are true parasites. The Mistletoe prefers Pomaceous trees to grow on, but is not exclusively confined to them; and it is rarely found on the Oak, whilst the Loranthus appears chiefly to select the latter as a support and feeder. Those of us who have been much through the southern counties of England know how abundantly the Mistletoe grows among the fruit-tree orchards there, where it not unfrequently gains complete mastery over some trees, and breaks them down by its weight. In Austria and some parts of the south of Europe, the Loranthus prevails similarly among the Oak trees of those countries.

Some twenty years ago a friend of mine, who was well known among amateur horticulturists, the late Mr. Bellenden Ker, visited Ireland, and felt interested with our success in growing the Mistletoe. He then told me he intended to proceed to Vienna, when I begged of him to try and get me some fresh ripe seeds of the Loranthus from the Oak trees of that neighbourhood. After his arrival there, he wrote to me and stated he had seen the parasite, but the seeds were not ripe. He, however, managed to arrange with the late Dr. Schott, Director of the Imperial Botanical Garden at Vienna, to send me some as soon as they ripened, which the latter accordingly did. On their arrival we lost no time in applying them to the bark of Oak trees, similarly as we had succeeded with the Mistletoe on the bark of Apple trees, &c. Our late foreman, Mr. Macardle, put on a number, and I tried a good many myself, some of which continued fresh-looking a whole year, but ultimately fell off without one of them taking root, a result which chagrined both of us very much. When thinking over the matter afterwards, it occurred to me we had probably not taken the right method of applying them, which made me long for another opportunity to try and establish them. This happily offered in 1869, when I met Dr. Fenzl, Professor of Botany to the University, Vienna, at the Botanical Congress, which was held at St. Petersburg, during that year, and who kindly sent to us the fine example of Loranthus europæus now before you in January 1870, when it was covered with ripe seeds. At the same time he stated that he thought we should not succeed in getting them to grow, as he had never known any instance of the plant having been propagated artificially save once. We, however, set to work with them. Mr. Keit, the propagator, tried a considerable number of the seeds in various ways on Oak trees, and probably I tried as many more myself, and Mr. Parnell, the

present foreman, put on a few also. Some were again made to adhere to the exterior of the bark, others were put under its epiphleum, and more under the endophleum, resting on the albuminous wood, but by none of these methods were we successful. It occurred to us to bruise gently the soft bud on a young shoot of the previous year, and insert the seed of the parasite in the centre of the partially bruised bud. By this method two of the seeds grew, one on the common Oak and one on the Turkey Oak, *Quercus Cerris*. Although the progress of their growth up to the present period has been remarkably slow, it is still sufficient to warrant me in reporting the success of the experiment. The seeds which were put on in January and February, 1870, soon became covered over with thin viscous gelatine, which hardened and appeared like transparent glue, in which state they remained until the spring of 1871, when it fell away, and soon afterwards a few young leaves of the parasite were pushed out from the bark of the Oak branch, thus showing it had taken root. The leaves continued to enlarge until the autumn of the same year, when they were subject to the natural habit of the plant, and dropped off deciduously. In April of last year, 1872, about a dozen leaves of the *Loranthus* grew at each of the places where those of 1871 had been, and continued healthy all the summer, until the fall of the leaf in autumn, when they again fell off. No branches have yet grown, but there can be no doubt that the parasite has taken vital hold of the trees; and, as I have detailed the method we took to propagate it, we may expect that other experimenters will endeavour to cultivate this curious plant, which, from so small a beginning, may ultimately become of frequent occurrence in the British Isles.

#### NOTES OF THE WEEK.

— We learn that the celebrated *Jardin Fleuriste*, of the city of Paris, which since the war has been in a ruinous condition, is at last to be entirely abolished, and the ground whereon it stood let for building purposes. A few years ago it was one of the most interesting and instructive gardens in existence.

— We regret that owing to our Index and Portrait Supplement not being strictly in accordance with the postal regulations, a charge of 2d. extra postage was made on each copy of our last issue. Such copies as have been refused on that account we shall be happy to replace, on application.

— We saw in Mr. Wills's houses at South Kensington the other day two of the finest specimens of *Cologyne cristata* we ever remember to have seen. They were immense plants, 4½ feet in diameter, and were laden with their beautiful white and yellow flowers, which last long in beauty, and which are so suitable for bouquet making and for similar purposes.

— The value of wild Sweet Violets was never, we imagine, so much enhanced as on the occasion of the funeral of the Emperor Napoleon III. at Chislehurst. The Violet was universally adopted on the day of the funeral by those present: 6d. and 1s. a bunch was readily obtained by the hawkers, who had heard that Violets would be in demand, and so a good supply was kept up, and some cartloads were gathered and disposed of in a few hours, many cottage families reaping a good harvest by the sale of the sweet-scented Violet.

— WINTER has come at last, and those who have empty icehouses will be enabled to fill them. The ice on the ornamental water at Moor Park on Tuesday last measured an inch and a half in thickness, and Mr. Cunningham informs us that skating has been briskly and safely performed on it. Skating in private grounds has now indeed become so fashionable that gardeners will soon have to be as expert in scraping, sweeping, and flooding ice, so as to keep it in good condition for that use, as they have hitherto been in keeping grass in order for cricket or croquet.

— AMONGST many beautiful Orchids in flower at present, in the nurseries of Messrs. Veitch, of Chelsea, we noticed an excellent plant of *Dendrobium crassinode* with several pseudo-bulbs well-furnished with flower buds. One of these bulbs measures 2 feet 8 inches in length, and is ornamented with 34 flowers; of *Dendrobium heterocarpum*, there were also some beautifully flowered specimens, one of which had no fewer than three dozen blooms on one of its pseudo-bulbs. Associated with these was a plant of Dawson's variety of *Laelia anceps*, bearing a fine spike of lovely creamy white flowers, the lips of which are tipped with purple, and the throat marked with purple and yellow; likewise a plant of the new and beautiful *Cypripedium Reichenbachii* bearing one flower spike. This

fine species has delicate pinkish flowers with side petals or "tails" about 4 inches in length, and produces a great many flowers on the same spike, which blooms and grows at the same time, one only being fully expanded at one time. In this collection we noticed, moreover, a plant of *Angraecum citratum*, bearing two flower spikes, each of which was about a foot and a half in length, and densely furnished with rudimentary buds. In two months time or so, we may therefore expect to see this plant in magnificent condition.

— A SECOND volume of that fine work on the plants of the East of Europe—Boissier's "*Flora orientalis*"—is announced as ready for publication.

— A GOOD memoir of Dr. Welwitsch, the discoverer of the wondrous *Welwitschia* and many other plants, appears in the January number of the *Journal of Botany*. It is written by Mr. Henry Trimen, and is accompanied by a very good portrait.

— ANOTHER step in the planting of the streets of Brighton with trees has been taken within the last few days. Two lines of fine young Elms (presented by the Earl of Chichester) have been planted on the outer skirts of the central pavement of the Steyne.

— IN the avenue at Torre Abbey, Torquay, there is a Chestnut tree which sends forth its leaves much earlier than any other. This year it is far in advance of any previous season, for already it has scores of leaves fully expanded, and all the leaf-buds are bursting into leaf.

— WE are glad to see that Messrs. E. G. Henderson offer in their new catalogue plants of the best American Blackberries. It may be as well to state that these are entirely distinct from and superior to our own Blackberries, and that they are well deserving of a trial among our small fruits. The kinds offered are the Lawton, Wilson's Early, and Kittaniny, which are known to be the best.

— *BOUYARDIA FLAVA* is now in good bloom at Messrs. E. G. Henderson's Wellington Nurseries, St. John's Wood. It flowers abundantly from all parts of the old bare wood of the past year, and is a most valuable acquisition. It may be readily brought into bloom in winter and early spring by being introduced to a warm house.

— AT a meeting of the Central Horticultural Society of France, M. Vavin recommended a novel mode of treating the Pampas Grass during the winter. This is simply to burn the exterior of the tufts in the end of autumn, and then leave them to themselves. Plants treated in this way, he says, will, in the following spring, push earlier and better than if they had been protected with mats or other coverings.

— ON Sunday week five excellent half-fat West Highland bullocks strayed into the woods from the Harrowstack Farm, in Westmoreland, and ate freely of the Yew trees that grow rankly there. Four have since died, and on being opened large quantities of Yew, undigested, filled the stomachs of all. The other is still unwell, but likely to recover. Large quantities of oil were administered, but without avail, except in the one case.

— WE have all heard more than was pleasant about the adulteration of coffee with chicory. But there is a lower deep. The Inland Revenue Board are "surprised to find" that there is a trade in adulterated chicory. A chicory-roaster has been detected mixing scorched rye with the article which he sells to the dealers as Chicory, and which they, in turn, would, no doubt, mix with and sell to the public as coffee. The roaster admitted that this has been his practice, but said that he was using up his whole remaining stock of adulterants, in order to start on a new system in consequence of the Food Adulteration Act of last Session.

— IT seems that there are not only fashionable flowers, but fashionable vegetables. This, at all events, is the case in Brussels, where some inventive *cordou-bleu* introduced a new vegetable at a Ministerial dinner, which has now become the *cibus divinum*. The fruiterer's shops exhibit placards in large type announcing the sale of Oxalis, to which generic name seedsmen, being more scientific, add the special denomination *cremata*. Unfortunately, however, the intrinsic excellence of the Oxalis is not equal to the fame it has acquired by appearing in such high society. It is a plant introduced into France some fifteen years ago, and cultivated in the *Jardin des Plantes*. It is, gastronomically, a failure, the herbaceous part of it resembling insipid Sorrel, and the bulbous part tasting like a bad Potato. Such a disappointment in the quality of the new plant matters little abroad, where there is a plethora of vegetables, but it suggests a passing remark on the limited nature of our ordinary stock. How seldom do we meet, for instance, with that useful plant Sorrel, with which the Oxalis is disadvantageously compared. Many excellent vegetables are, indeed, known in England, but they do not find their way into our markets in any sufficient quantity, and this is the case with some useful roots, such as Salsify, the neglect of which is not explained by any particular difficulty or expense in its cultivation.

## THE INDOOR GARDEN.

### ORCHID HOUSES IN THE NATURAL STYLE.

THE accompanying sketch of an Orchid house in the natural style gives some idea of the beauty and grace of that fine tribe of plants when judiciously arranged. Still, however beautiful houses arranged in this manner may be made to appear, from an æsthetic point of view I can scarcely hope for their general adoption at present, though even the most enthusiastic admirer of Orchids must admit that our Orchid houses, as at present arranged, are not generally noted for any special beauty or elegance, in any other than a floral sense. Indeed, when the generality of Orchidaceous plants are out of flower, they do not give a tithe of the pleasure that an ordinary observer would derive from a collection of the commonest Ferns or Succulent plants. To the professional Orchid grower or enthusiastic amateur, there is a certain attractive beauty in the strong growths, fresh foliage, or plump pseudo-bulbs, but an ordinary visitor overlooks these minute details, the general effect of the whole only being taken into consideration. Some Orchids, however, have a graceful habit, as *Aerides*, *Vandas*, and a few others, but in general they are unattractive when not in bloom. We get a step nearer to natural arrangement, and see a little more of its beauty when we group gracefully-habited Ferns and Palms along with our Orchids. As I have before pointed out, Orchids grow luxuriantly in their native habitats in close contiguity with Ferns, Melastomads, Grasses, and Palms, and it is possible to follow nature to a certain extent in the way of natural arrangement here in our Orchid houses at home. I am quite well aware of the practical difficulties that present themselves to our notice, and know that these in some cases are amply sufficient to preclude the possibility of the natural system being attempted, but there are cases in which this plan may be followed out judiciously, and with the best possible results. Terrestrial Orchids in pots are portable, and more convenient for many reasons than when planted out, though I very much doubt whether they ever grow so luxuriantly as they would if planted out in a suitable structure. In a state of nature Orchids grow with a wild luxuriance quite unknown to us, their aerial roots extending in all directions in quest of food and moisture; and they would grow more vigorously in our plant houses if planted out in suitable composts, though, as a matter of course, this plan could only be adopted in places where there was no probability of their having to be removed. All

that are specially amenable to this course of treatment, and in this respect cultivators should be judicious, only selecting such plants as are likely to succeed and give satisfaction. There are several beautiful Ferneries arranged in the natural style in this country, with fountains and little trickling brooks bordered by moist banks of sphagnum and turf, and to these the addition of a few Orchids would be a marked improvement. A moist, spongy bank partially shaded in such a structure would be just the situation in which to plant out the glorious *Disa grandiflora*, and to grow it in perfection. It has grown and flowered out-of-doors during the summer months in this country, but the chances of success would be far greater under

the above conditions than when subjected to either the vicissitudes of our climate or to having its eager roots cramped within the circumference of an earthenware pan. Give it a chance on one of these moist banks, where its roots can ramify in all directions, and its fresh vigorous foliage will bid defiance to thrips or red spider, and it will form an object of beauty not easily excelled. There are other terrestrial Orchids admirably adapted for planting out, such as the evergreen *Calanthes*, *Phajus* and *Sobralias*. *Phajus grandifolius* and *P. Wallichii* would soon establish themselves and make noble specimens, being gross feeders and very abundant bloomers. The golden-flowered *Cyrtopora flava* and many other terrestrial Orchids from India, South America, and the Cape, might be grown in perfection if planted out in suitable situations, since it is almost impossible to do justice to them when grown in pots. Our illustration, which represents an Orchid-house arranged in a picturesque manner, shows what the idea is when properly carried out. The pipe carrying the water for the cascade passes round the boiler. The plants have a graceful appearance, and the *tout ensemble* is considerably heightened by the little cascade tumbling from the partly hidden rockwork. It is easy to recognise such plants as *Peristeria elata* (Dove plant), some species of *Oncidium* and *Cyenoches Loddigesii* in the foreground, while *Cœlia macrostachya*, *Senticaria Steelii*, *Renan-*

Orchid House in the natural style.

*thera coccinea*, *Vanilla planifolia*, and a *Stanhopea* or two complete the group. The water below might have been utilized by the culture of some of the smaller *Nymphaeas*, or other aquatic plants. In houses of this kind suitable openings could be left in the rockwork, so as to introduce pots containing flowering plants as they come into bloom; and by adopting this system, a naturally arranged house might always be kept gay with choice exotics, while Ferns, Selaginellas, and Mosses, together with a few trailing plants, would form an appropriate background to the delicate colours of the fragrant flowers.

F. W. B.

## PAULLINIA THALICTRIFOLIA.

This is one of the most beautiful of recently introduced plants, and one that cannot fail to become a favourite. It is a native of the southern Brazils, whence it was introduced by Mr. Bowman to the nurseries of Messrs. Veitch & Sons, of Chelsea. In general appearance it is not unlike a minutely cut leaved *Adiantum*, and, indeed, so much does it resemble a Fern that it might easily be mistaken for one. It, however, is in reality a hardwooded plant belonging to the Order Sapindaceae. The leaves are of a rich shade of green, and as the specific name implies, they closely resemble in shape those of some species of dwarf *Thalictrum*. The young branches are clothed with a velvety down of a greenish-chocolate colour, and the woody stems are also tinged with brown. The true habit of the plant is semi-scandent, a character which it always assumes in its native country, where, as the plants become aged, they lose that compactness of growth so necessary to their attractiveness in this country, and become coarse and straggling. The graceful appearance which they have when in a young state is admirably represented in the accompanying illustration (see p. 87). If only required for decorative purposes there should be no inclination to make the plants produce flowers, which are inconspicuous; therefore the main object should be to have plenty of healthy foliage. To secure this, the plant should be grown in stove temperature, and if one part of the stove is more adapted to its growth than another, it is the dampest part. After this plant came into the possession of Messrs. Veitch, and before its true value became known, some plants of it were placed in a corner of an old very damp stove pit, in which position they grew wonderfully strong, and quite surpassed in vigour and beauty those that were, as was then supposed, placed under more advantageous circumstances, *i.e.*, in drier and lighter parts of other houses. Care is therefore now taken to keep them where abundant atmospheric moisture can be supplied, and for this purpose they are in some cases plunged amongst *Sphagnum* and in others the pots are set on shelves that are overlaid with an inch or two of the same material, which is constantly kept moist by being sprinkled with the syringe. This plant may be grown to train on a small trellis or to alix to short rafters, but the best mode is to grow it so as to form little well foliated specimens. A compost consisting of two parts good substantial peat and one of loam, together with some silver sand, suits it admirably.

W. F.

## CANTUA DEPENDENS.

If any of your readers have ever flowered this plant under pot cultivation, they have certainly been more fortunate than the majority of cultivators. When first introduced by Messrs. Veitch & Son, then of Exeter, blooming examples were shown at a meeting of the Horticultural Society in Regent Street and Chiswick in pots securely mossed down; and therefore, as the whole of the great plant growers of that time failed to bloom the plant, I have reason to infer that the specimens exhibited were cut from a specimen planted out which was known to bloom annually in the Exeter establishment. I well recollect the anxiety with which I waited for and welcomed the plant when first distributed, thinking, or rather believing, we were about to receive something that would form a gem of the first water, even in the most select collection of stove or greenhouse plants. But I was doomed to disappointment; the plant grew freely enough, and made handsome specimens, but the harvest of bloom which I expected to reward my trouble never presented itself. Every scheme to induce the blooming principle failed, not only with one, but with, I may say, every grower in the country. Disheartened, the plant was consigned to the rubbish heap among the outcasts, and I ceased to think of it from that time until very recently, except as being worthless. In the spring of last year I was invited to visit the garden of Mr. Marriott, Cropwell Butler, near Nottingham, when, in looking through the conservatory I observed a blaze of gay flowers, depending from standard plants each about 4 feet high, splendid racemes, or rather corymbs, of tubular flowers, each 3 or 4 inches long, bright crimson with an orange violet throat. I knew the plant perfectly, but was some time before I could call its name to mind.

I had seen it blooming when planted in the conservatory against a sunny wall or pillar, but, as far as I can learn, Mr. Marriott's is the only garden in which the plant has bloomed successfully year after year. Nor is there any mystery in its treatment. The plants, though 3 to 4 feet high, were growing in 8-inch or 10-inch pots, in common loam and leaf-mould; and, rather than bearing evidence of luxurious treatment, they wore a somewhat neglected appearance. This was the key to their successful treatment; for, upon inquiry, I found that the plants, after they had done blooming—and, be it remembered, they flower for several months, say from April to the end of June, according to the temperature in which they may be kept—were dried off for a short time, and then cut close in; that is, the shoots which were made last year, and which will bloom this spring, will be cut back, after they have ceased blooming, to within two or three joints of the wood from which they started. After they had broken in the greenhouse and been hardened, they were placed in front of a south wall in the full sun, liberally supplied with water during the early growing season, and then subjected to autumn treatment, with a limited but sufficient supply of water, which had the effect of securing the thorough maturation of the wood. I am glad to record this much of one of Flora's most beautiful productions, because, the principles of cultivation being understood, a little neglect will not kill it, and consequently any intelligent amateur may grow it in perfection. To convey an idea of the beauty of this plant, I may say to those who have seen *Fuchsia corymbiflora* or *fulgens* blooming in their best form, that the *Cantua* produces its flowers in the same manner, the depending spike and spikelets frequently being a foot in length. To conceive anything more brilliantly striking than a finely-bloomed plant of this would be difficult.

Passing to cultural particulars, the *Cantuas* are propagated readily by cuttings of the partly ripened wood in the growing season. These must be prepared in the usual manner, and put in sandy soil under a bell glass. For the first two or three weeks, until they are callused, the cuttings must be subjected to cool treatment; but after the callus has formed, the pots may be placed in a gentle bottom heat, and a temperature of 55° to 65°, when the roots will protrude, and the cuttings will start into active growth. Allow them to grow for a week or two to gain strength, then pinch off the tops, and as soon as side shoots are produced, pot them in small pots, taking care to check them as little as possible. Retain the young plants in the same temperature until they are established, and then gradually inure them to the greenhouse. Presuming the cuttings to be rooted immediately, I should endeavour to get them so strong, and thoroughly established by the end of June that when cut boldly back they would show up five, eight, or more branches. I would then shift the strongest plants into 6-inch pots, the others into smaller ones; protect them for a fortnight until fresh roots are made, and gradually inuring, place them in the full sun. From each plant I should endeavour to carry up as many equally balanced shoots as I could get, not stopping them, but allowing them to attain their full stature. Carefully supplying water through September and October—giving sufficient to sustain healthy root action, but not more—I should expect the plants to produce bloom in the following season. This, however, would be but preliminary treatment, as it would be after the second and future seasons that I should expect the full and complete development of the plants. After pruning, and when the plants have broken into growth in the second season, repot them from the 6-inch into 8-inch pots, and continue this kind of small shift every season. Place them in the hottest and most sunny part of the garden, turning them weekly to keep the sides equal. When the pots are full of roots, assist the plants by waterings of weak liquid manure during the early growth of the shoots, and then make sure of thorough maturation by gradually withdrawing the supply. In this way success in blooming may be considered certain. The best soil may well consist of three parts rich fibrous loam, with a fourth part of leaf-mould, and sufficient small charcoal or broken oyster shells and gritty sand to make the whole healthy and workable. Pot firmly, and the result must be certain. The plant is subject to red spider, thrips, and fly, but syringings with soap, sulphur, and tobacco water will destroy all these. A.

GARDEN DESTROYERS.

THE WINTER MOTH.

(CHEIMATOBIA BRUMATA.)

THIS is one of the most injurious insects to fruit trees that we have in this country. In many points in its structure and habits it is very similar to the Lime-looper (*Hybernia defoliaria*), as in it the female is nearly wingless. Like it, it is a winter insect, the perfect moth only appearing in October, November, and December. The males come out first, and sit quietly during the day in some concealed place; but come flying out at night seeking the female, whom they generally find sitting at rest on the stem of a tree. Like the Lime-looper, too, it undergoes its metamorphosis in the ground, and when the perfect insect emerges from the chrysalis, the female has to creep up the trees to lay her eggs near the place where the larvæ will find their food. She lays them singly on the buds, or in their vicinity, or on the back of the twigs and branches, or in crevices in the bark. They are glued firmly on, and, although laid in November and December, and left exposed to the severity of winter, they remain uninjured until next spring, when they come out about the beginning of April. The eggs are at first light greenish, but gradually

*Cheimatobia brumata.*—Male and female, natural size.

become darker, passing through the stages of orange and olive, until at last they become brown. They are usually hatched about the same time that the buds expand: but not always, for it happens at times that they come out before the buds, in which case their instinct leads them to attack the unopened buds, and to eat their way into the heart. When the bud is half expanded, the small young caterpillar makes a fine web between the calyx and the petals of the flower buds, or between the leaves of the leaf buds, within which they lie concealed and protected, so that it is very difficult to observe them. When the leaves are expanded a little later, the caterpillars make a sort of nest or tent, composed of two or three leaves tied or glued together, and it is the way in which the buds, whether flower or leaf-buds, are glued together so as to be prevented from expanding properly that most readily betrays their presence. When the fruit is formed, they also attack it, and they consume it almost entirely. It has the same habit as the Lime-looper of hanging, swinging by a short thread from the leaves. At first its colour is grey, but ere long it usually changes into green. Examined more closely, a darkish stripe is to be seen running down the middle of the back, and three (or sometimes four) narrow white stripes down each side; but these markings are not conspicuous. A superficial observer would call the caterpillar green, but the colour

varies in different individuals: sometimes, instead of green, it is olive-brown, or even blackish brown. It takes about a month or six weeks to feed to maturity; so that it is usually full fed in the month of May, when it descends to the ground and buries itself a little under it, and there passes into the chrysalis, which is reddish brown. The moth does not always appear in winter; sometimes it remains in the pupa state until spring, and only lays its eggs then, which of course do not come out so soon as those laid in November. The perfect moth, male and female, is figured of the size of nature in the accompanying woodcut. The male has the fore wings of an ash-grey colour, with darker waved bars, and the hind wings pale. The female is of the same colour as the male (perhaps a trifle darker); but her wings are very short, and not adapted to flight. She runs about, however, with considerable activity.

This moth feeds on all kinds of trees, and of course, where fruit trees are, they suffer likewise, but they are certainly not more exposed to its attacks than other trees. It is, however, chiefly in connection with them that we have our attention drawn to this moth, and the reason is obvious. The caterpillar attacks the flower-bud, and it is usually only in fruit trees that we care much whether the flower-buds are meddled with or not. A Hornbeam may have all its flower-buds destroyed by it without our noticing it, or at least distressing ourselves about it; but touch our fruit buds, and that is quite another affair. In all fruit districts, therefore, and more particularly in our cider counties, the winter moth is a very important personage. We have already, under the head of *Hybernia defoliaria*, mentioned the precautions which have been successfully adopted against it. The same means apply to this species. Smear the stems of the trees in the end of October, the month of November, and the beginning of December, with a broad band near the ground of a sticky mixture composed of tar and cart grease in equal proportions. Across this band the females cannot pass. They become entangled in it, cannot escape, and are detained until they die. The mixture retains its adhesive properties for several days, but the operator must be cautious to renew it before it has lost them; and as to this he must satisfy himself by constant inspection. It is well to begin protecting the trees before the moths appear, but if this be thought unnecessary, the stems of the trees should be examined by lantern-light every night after the middle of October; and as soon as the presence of the moth is noted, a ring of the sticky material should be daubed round the stem. Mr. Newman ("British Moths") thus enforces this advice. From the 20th of October to the 20th of December, (says he), the gardener should examine his plantation every evening with candle and lantern, and destroy by hand all the moths within reach. The couples are mostly on the stem, or within reach, and very visible. If he finds the moths numerous—and sometimes they are (the men say) as thick as bees—he should, the following day, daub his trees with a ring of this composition round the stem or branches in the most convenient places, taking care to leave no other path to the tree, such as side shoots, or contact with the branches of other trees, for the ascent of the female. By these means hundreds—nay thousands—of females have been destroyed on a single plantation in one night; and as each female is calculated to lay two hundred eggs, the destruction of caterpillars for the following season is very great. The daub must be renewed every few days, and the trees should be well shaken when it is applied, to dislodge, as far as possible, any female moths that are in them. The composition loses its stickiness in frosty weather, but the moths do not then come abroad. Prof. Westwood has recommended bird-lime instead of the tarry mixture, as requiring less frequent renewal; but this is much more costly and difficult to procure. Mr. Newman also wisely recommends that where this moth is prevalent, the pruning of fruit trees should be delayed until after Christmas, that a portion of the eggs may possibly be carried away with the prunings, and these should be burned.

The titmice and other small birds do much service in searching the buds for the young larvæ. They have, indeed, been said also to destroy many sound buds in their search for them; but even assuming this to be true (which we do not admit to any great extent) the good they do much more than counterbalances the attendant evil.

## THE PROPAGATOR.

### INFLUENCE OF FOREIGN POLLEN ON FRUIT.

BY C. J. MAXIMOWICZ.

It is universally admitted that, in the fertilization of an organism with the pollen or farina of another species, the influence of the foreign pollen or farina on the offspring produced is very distinctly observable. But the cases where this influence has previously shown itself in the mother plant, in a change of form, colour, or size, in the fruit produced, have been hitherto exceedingly rare. The few instances may be found collected in Gaertner or Darwin. Thus Manz asserts that he observed different kinds of fruit on a Pear tree, of which a number of blossoms had been castrated, and, as he supposed, fertilized afterwards by neighbouring trees. Pavis maintained that the fruit of Apples, Melons,\* and Maize underwent alteration in form, colour, and special qualities when they were planted near other kinds. Bradley even says that he had seen an Apple which was sweet on one side and sour on the other, and one half of which became soft when boiled, while the other remained hard. But these are only observations and not experimental results. Wiegmann first obtained the latter in Peas. Gaertner tested experimentally many of the statements which we have quoted, and made experiments on other plants besides. He was only able, however, to confirm Wiegmann's results to a certain extent. He is therefore disposed (and with much reason) to attribute the majority of such cases to variation in the individual; he allows, however, as a rare exception, the possibility of change even in the mother plant itself. Other observers (as, for example, Knight, and recently Nägeli) deny even the possibility of such an influence. More recently Darwin has again quoted cases where, by crossing yellow and dark Maize, cobs were produced which contained both yellow and dark grains. Hildebrand confirms these observations, and further cites the instance of an Apple which bore traces in its marking of the influence of another sort. But whilst the question has been in these cases only a variation in the colour, in the three which follow we find it affecting the form. Hartsen has seen on *Solanum edule* (the well-known Egg-plant) a fruit which in colour, size, and shape exactly resembled a Tomato, and possessed only the greater dryness and firmness of the flesh of the Egg fruit, besides the smooth border of the seed, which in the Tomato is villous. Dr. Kanitz met with a case of a hybrid fruit, between *Lycopersium esculentum* and *Capsicum annuum*. Fritz Muller fertilized *Cattleya Leopoldi* with *Epidendrum cinnabarinum*, and obtained seeds of the former with the shape belonging to the latter. Meehan, lastly, observed that the bough of a Pear tree, which had always been altogether unfruitful, projected into the boughs of a neighbouring Apple tree. Fruits were produced which in skin and flesh were altogether Apples, and had only the seeds, carpellary partitions, and stalk of the Pear.

These are all the cases with which I am acquainted. Considering, then, that the observations of Bradley, which are the earliest, date from the year 1721, and that the list has only increased very slowly, notwithstanding the vast opportunities for noticing these cases which botanists and gardeners have had in crossing different species of plants, we must allow that Gaertner was quite justified in declaring that the immediate influence of foreign pollen upon the mother plant is a rare exception. If we agree with Gaertner in excluding from the list, as possibly due only to bad-variation, those cases which are not the result of direct experiment, the only well-established ones which remain are those of Maize, Peas, and *Cattleya Leopoldi*. The amount of evidence being so limited, it has seemed desirable to me to publish a case from my own observation, where, two species being reciprocally cross-fertilized, the influence of the foreign pollen upon the fruit fertilized by it has been distinctly recognizable. During the last summer I cultivated indoors a number of species of *Lilium*, in order to study their specific distinctions. They all came into bloom early, and before those in the open ground. My house being surrounded by high trees for some distance, and there being no other cultivation of Lilies in the neighbourhood, no question could arise as to the influence of foreign pollen. Moreover, my Lilies did not come into bloom simultaneously, but one after the other. The capsules being far from well known in all the species, I fertilized the flowers (with which I was better acquainted) as they expanded themselves. I did this when possible with the pollen of their own species, but of a different individual, or, failing this, with the flower's own pollen. The latter was the most frequent; yet the capsule was fully developed in most cases, although it contained fewer seeds; it is well known, however, that in the Liliaceæ self-fertilization is reputed to be more successful than in other families.†

\* Livingstone states (and the incident has not, I think, been quoted) that in the case of *Citrullus vulgaris*, Schrad., which varies with sweet and bitter fruit, "Melons in a garden may be made bitter by a few bitter Kengwe in the vicinity. The bees convey the pollen from one to the other." (Travels in S. Africa, p. 49.)

† With *L. tigrinum* alone I have failed in producing fruit even in the open

*Lilium davuricum*, (Gawler (*L. spectabile*, Link), and *L. bulbiferum*, L., the two species which are the subject of this paper, were amongst the earliest which flowered with me. Both are described by numerous recent authors as forms of one and the same species.\* They admit, however, of being distinguished from one another by differences which lie in organs the study of which in the genus *Lilium* has hitherto been very much neglected, namely the bulb and the fruit. The bulb of *L. bulbiferum* is firm and compact, and composed of innumerable pointed scales closely and tightly packed in many rows. The outer scales are attached by their broadest part, and are gradually attenuated to a point; the inner scales are slightly contracted above the base, and are widened out again towards the apex. Taking in the hand for comparison a bulb of *L. davuricum*, its loose structure immediately strikes us with surprise; it allows mere pressure to crush the whole bulb into separate scales. These are smaller and are curved away from one another, so that the arrangement is imbricated, and the scales can be distinctly counted, while in the former species only the points of the inner scales are visible.

The author describes minutely the form of the scales. Even the outermost exhibit above the base a distinct contraction; in the next row this becomes so evident that the scale appears to have a stalk. If, however, a young bulb, such as occasionally forms itself in a scale-axil at the base of the previous year's stem, is examined, the outermost scales are simply ovate without any trace of a contraction above the base. These are probably absent from the old bulbs through decay. Although a contraction of the inner scales above the base takes place even in *L. bulbiferum*, it is very different from the constriction in *L. davuricum*, which further inwards in the bulb assumes more and more the character of an articulation. The scales break off at the constricted point very readily and smoothly. The constriction runs quite round the scales; and occasionally broods of small bulbs break out on the broken off scales at the articulation. From what has been said, the difference in the structure of the bulb in the two species becomes sufficiently evident. It has, in fact, long been known to gardeners, who amongst hundreds of bulbs can pick out those of *L. davuricum* with the greatest certainty.‡

Scarcely less distinct are the differences of both species in the capsules; and as they readily produce fruit, it has been already repeatedly described.‡ The capsule of *L. bulbiferum* is long and narrow, almost cylindrical, 6-grooved, and the top deeply umbilicate, because each cell projects in an elevated point-like knob. The seeds have a very narrow wing: "seminum discus ala octuplo latior," says Lallemand. The capsule of *L. davuricum* is shorter and broader, nearly obovate, 6-grooved, and the top flat and almost truncate, from the cells being shortly rounded off. The seeds have a very broad wing, almost half the width of the seed. Both species also afford good distinctions in the floccose hairiness of the long-pointed leaves, and the externally pubescent flowers of *L. davuricum*, contrasted with the absence of hairs, the lanceolate pointed leaves, and the externally glabrous flowers of *L. bulbiferum*. These characters, however, are often insufficient to diagnose the species, because in gardens so many forms present themselves (possibly originated through hybridisation) that one may often be in doubt as to the species in the absence of bulb or capsule to settle the matter.§

As I believed I had noticed that in *L. bulbiferum* the scales of different bulbs sometimes exhibited a very indistinct contraction above the base, while sometimes it was distinct, it occurred to me whether in the last case I might not have had a hybrid between this species and *L. davuricum*. I fertilized therefore a flower of *L. bulbiferum* with the pollen of *L. davuricum*, and a flower of this with the pollen of the first. This was the only fertilization effected, because these individuals bore only a single flower each, and I neglected the operation in the case of others. The ovaries of both species swelled up and developed. But after the capsule of *L. davuricum* had become about 2 inches long and 5 lines in diameter, it ceased further growth and dried up. It had, however, sufficiently developed itself to show the characteristic form of the capsule of *L.*

aur, and after cross-fertilizing numerous individuals. The reason was, perhaps, because I neglected at first to break off the small axillary bulbs; and afterwards it had become too late in the autumn.

\* Asa Gray, Mem. Amer. Acad. n. s. vi. p. 115; Miquel, Proc. Fl. Jap. 320; very recently, again, Baker's new synopsis of the genus *Lilium*, Gard. Chron., 1871, p. 1034. Miquel separates the two plants in the Ann. Mus. Lug. Bat. iii. 156; Baker also keeps them apart as sub-species, relying upon the absence of axillary bulbs in *L. davuricum* as the main distinction.

† *L. avenaceum*, Fisch., exhibits a similar appearance of articulation (see my diagnosis and the figure in Regel's Gartendora, 1865, p. 290, t. 45). Compare also, and on other structural distinctions of Lily-bulbs, my essay on the Lilies of Japan in the Arbeiten des kais. Bot. Gartens.

‡ See the excellent essay of Lallemand in the Index sextus Sem. Horti botan. Petrop. 1839, pp. 54, 58. For the capsule of *L. davuricum* see Glehn. Supp. ad Ind. Sem. H. Petrop. 1868, p. 19 (under *L. spectabile*). For a figure, Trautvetter, Fl. Ross. III. t. 19. f. g.

§ Baker, in fact, describes *L. bulbiferum* proper as having the stem, especially in the upper part, clothed with scattered pubescence, and the perianth slightly cotony externally, while in *L. davuricum* the stem is nearly smooth.

bulbiferum, the male parent. On the other hand the capsule of *L. bulbiferum* grew and ripened, and was not cut off till it had dehisced; it had completely the character of the male parent—that is, of *L. davuricum*.

Both species, then, had so completely changed their capsules, that, having forgotten to which the long and deeply umbilicate, and the short and flat one belonged, I did not observe the wonderful state of the case till I was about to incorporate the *corpus delicti* into the herbarium, and compared it previously with descriptions and other fruit-specimens. This inattention of mine was very blameable, because, believing the other capsule which did not complete its growth of no value, I allowed it to drop. The developed capsule I have carefully preserved: it contains about 130 seeds; a few, not exceeding a dozen, may have been lost. The breadth of the wing was about the mean of what it is in the two parents; it varied from one-third to one-sixth of the breadth of the seed. About fifty of the seeds were abortive; about seventy were well developed, of the normal

ment, and in the event of its not succeeding, to bear in mind that Gaertner was unsuccessful in confirming the observations of Pavis, while Savi, Hildebrand, and others succeeded. I should like to invite all who are interested to repeat my experiments, since probably by that means the second objection might be weakened—namely, that this is a solitary case, which proves nothing, and that it is an accidental sportive variation. Other researches will probably prevent me following further observations of this kind myself. The weightiest objection would be this, that the *L. bulbiferum* with which I experimented was already itself a hybrid, that this was the explanation of its fertilization by one of its parents turning out so successfully, and that it probably, independently of this, possessed (owing to its hybrid origin) the capsule which is peculiar to *L. davuricum*. That this is probable I have already shown in describing the bulbs; and I do not know what form its capsule would have had if it had been fertilized with its own pollen or that of a genuine individual, inasmuch as the capsule which I obtained

*Paullinia Thalictrifolia* (see p. 54).

size of the seeds of these species (8 mm. long, 5 mm. broad), and supplied with an apparently well developed embryo, the characteristic slightly curved, longish, linear form of which was readily recognised by transmitted light.

I would not attach any great importance to the seeds having a middle form between that of the two parents, because the sizes hardly allow themselves to be expressed with the exactness which Lallemand assigns them. The wing of the seed may be bent round or compressed towards the border, and in measuring the breadth of the wing this compression cannot be taken into account. What objections can be advanced against the case which I have just related? I can foresee the following:—

First of all, some one may say that the whole observation rests upon one fundamental error, an interchange, and so forth. The circumstantial explanation I have given above, I hope, speaks for itself. An obstinate doubter I can only invite to imitate the experi-

ment, and in the event of its not succeeding, to bear in mind that Gaertner was unsuccessful in confirming the observations of Pavis, while Savi, Hildebrand, and others succeeded.

I should like to invite all who are interested to repeat my experiments, since probably by that means the second objection might be weakened—namely, that this is a solitary case, which proves nothing, and that it is an accidental sportive variation. Other researches will probably prevent me following further observations of this kind myself. The weightiest objection would be this, that the *L. bulbiferum* with which I experimented was already itself a hybrid, that this was the explanation of its fertilization by one of its parents turning out so successfully, and that it probably, independently of this, possessed (owing to its hybrid origin) the capsule which is peculiar to *L. davuricum*. That this is probable I have already shown in describing the bulbs; and I do not know what form its capsule would have had if it had been fertilized with its own pollen or that of a genuine individual, inasmuch as the capsule which I obtained

\* The only example of the fruit of *L. bulbiferum* in the Kew Herbarium is one from Corsica collected by Mabilie. This, Mr. Baker assures me, is indubitably the true plant. The capsule, however, almost precisely accords with that attributed to *L. davuricum*. This, so far, weakens the case as far as *L. bulbiferum* is concerned, and confirms what the author himself states above; it leaves, however, matters unaffected with respect to *L. davuricum*.

## THE FRUIT GARDEN.

### REQUISITES FOR PEAR CULTURE.

The following inquiry has been made by a landowner who proposes to plant a large Pear orchard for marketing, viz.: "What points must I attend to to avoid failure, which so many have met with?" In answer, we would say that the first requisite is

**EXPERIENCE.**—We may learn a great deal from advice and directions, but after all, a certain amount of experience is absolutely essential. Different localities, soils, aspects &c., may require different treatment, and these modifying influences can be fully understood only by a certain amount of practical observation: We may get much of this from our neighbours, if they have made the trial, and so obtain the advantage of their losses and gains at their expense. If Pear trees have failed in a certain neighbourhood, under all kinds of management, the prospect is not encouraging, and yet there may be detrimental influences capable of being removed. But it would not be advisable to plant largely in such a place until a full trial should promise success. We will proceed to point out more in detail what are usually found essential requisites.

**SOIL.**—This may vary greatly in appearance, and yet grow good Pears. We have never seen better than where grown on trees standing in sandy soils in one locality, and in strong clay in another. Actual trial must test the question. But the soil must have thorough natural or artificial drainage. We cannot expect a good orchard where water remains several weeks in spring a foot or two below the surface. If holes dug 2 feet deep for the purpose early in spring will hold it several days, Pear trees will be a doubtful experiment, unless thorough under-drainage is resorted to.

**CULTIVATION.**—Soils vary greatly in fertility, and the amount of cultivation must depend on circumstances. The true guide is to observe the annual growth, which, on bearing trees, should not exceed 2 feet. As trees become old, 1 foot will indicate sufficient vigour. On dwarf Pears, kept highly cultivated and manured, as they always should be, and sufficiently pruned, a more rapid growth would be proper. The healthiest trees are those of medium growth, not so much enriched as to cause canker, nor so feeble as to give small and poor growth.

**PRUNING** must also vary with circumstances. All dwarf trees need frequent pruning, to keep the tree in symmetrical shape, to prevent it from becoming stunted by too great a mass of fruit spurs, to equalise the vigour over the whole, and to give good large fruit instead of a quantity of small rubbish. To impart vigour to the growth, the pruning should be done before the buds swell.

**THINNING THE FRUIT.**—This is of greater importance than many suppose, and is not sufficiently attended to. Overcrops have two bad results. They exhaust the tree, and the fruit is poor in quality. When thinned, the Pears are larger in size, better in quality, and sell for much higher prices. A neighbour, last season, had one-half of his Pears picked off when small from a part of his trees, and another part was left unthinned. The Pears on the thinned trees grew so much larger that they actually exceeded in bushels those on the unthinned trees, and he said it would have been better had he taken off two-thirds of the number. The objection that the thinning increases the labour and expense is imaginary, for it is easier to pick off Pears when small than afterwards, and a few large specimens remaining are more rapidly gathered than many of inferior size.

**SELECTION OF VARIETIES.**—In making a selection of sorts for a market orchard, two requisites must be attended to. They should be good in quality, and they must be popular. Private growers may please themselves, but the market grower must not only grow good kinds, but those that are certain to be in demand in the market. *Cultivator.*

### FRUIT CULTURE IN CALIFORNIA.

MR. NORDHOFF has, in his new book on California, an interesting chapter on the cultivation of fruit in that country, which has been attended with a degree of success that seems almost incredible. The Orange, Almond, Olive, Lemon, Citron, Lime, and English Walnut are the fruits to which attention has been specially directed for some

years in the southern counties, although they grow in many other parts of the State. The Almond begins to bear at three years from the bud, and at five years will yield 12 lbs. to the tree, or 1,200 lbs. to the acre, which at twenty cents a pound would give 240 dollars an acre. They bear for several years, and at eight years may be reckoned on for 20 lbs. to the tree, which would give 400 dollars to the acre. The Almonds fall to the ground when they are ripe; the husk is easily picked off; and as the harvest-time is dry, the shells are bright and clean. The Olive grows slowly at first, beginning to bear at four years, but does not yield a full crop until the tenth or twelfth year. It then returns on an average for the orchard about twenty-five gallons of Olives for each tree. It is more profitable to make the fruit into oil than to pickle it. From five to seven gallons of ripe Olives go to one gallon of oil. The Citron, which bears in four or five years, is also a profitable crop. It is a straggling tall shrub; three of them in Los Angeles, bore, at four years, without special care last year, 45 dollars worth of fruit. The Lemon, which becomes a stately fan-sprading tree, bears in ten years a valuable crop. It is not yet planted in orchards to a great extent; one tree, ten years old, which I saw in Los Angeles, yielded 600 Lemons; one fifteen years old, bore 2,000 Lemons, which fetch in San Francisco 30 dollars per 1,000.

### ORANGE CULTURE.

Last I come to the Orange. "All these trees do well, and are profitable," said an Orange cultivator to me; "but they don't compare with the Orange; when you have a bearing Orange orchard, it is like finding money in the street." Los Angeles is, at present, the centre of the Orange culture in this State. The tree grows well in all Southern California, wherever water can be had for irrigation. It does best nearest the mountains, among the foot-hills, probably because it there gets a more uniform temperature; and I think I have noticed in orchards at Los Angeles, San Gabriel, and near San Bernardino, that it is grateful for such protection as house, out-buildings, or hedges give it from severe winds. At Los Angeles the frosts are sometimes severe enough to nip the tender leaves of the young plants, and on the plain near San Bernardino I found that year-old plants were protected with some slight covering during the past winter, which everybody tells me has been uncommonly hard. Sixty Orange trees are commonly planted to the acre. They may be safely transplanted at three or even four years, if care is used to keep the air from the roots. They grow from seed; and it is believed in California that grafting does not change or improve the fruit. It begins to bear in from six to eight years from the seed, and yields a crop for market at ten years. With good thorough culture and irrigation, it is a healthy tree; if it is neglected, or if the "Gopher" has gnawed its roots, the scale insect appears; but a diseased tree is very rarely seen in the orchard. It is in California, as elsewhere, a tremendous bearer. At Los Angeles I saw two trees in an orchard, one seventeen years old, from which 2,800 Oranges had been picked, and it still contained a few; the other, three years younger, had yielded 2,000 Oranges. At from ten to twelve years from the seed the tree usually bears 1,000 Oranges, and they are selling now in San Francisco for from 15 dollars to 35 dollars per 1,000.

I have satisfied myself, by examination of nearly all the bearing orchards in the southern counties, and by comparing the evidence of their owners, that at fifteen years from the seed, or twelve years from the planting of three-year-old trees, an Orange orchard which has been faithfully cared for, and is favourably situated, will bear an average of 1,000 Oranges to the tree. This would give, at twenty dollars per 1,000, a low average—a product of 1,200 dollars per acre. One man can care for twenty acres of such an orchard; and every other expense, including picking, boxes, shipping, and commissions in San Francisco, is covered by five dollars per 1,000. The net profit per acre would, therefore, be a trifle less than 900 dollars. To show that this is not an over-statement, I will tell you that I have been in an orchard of less than nine acres, which has produced for its owner for several years in succession a clear profit of over 8,000 dollars. An orchard of forty acres in Los Angeles is reported to me to bring a clear rent of 15,000 dollars per annum; and the lessee is believed to have made a fortune for himself. You will probably believe, after all, that I have exaggerated the profits of this business, but the Orange-growers of Los Angeles will smile at the extreme moderation of my statement. "People tell large stories about Oranges," said one such man to me; "but the truth is big enough—at ten or twelve years trees may be safely counted on to average ten dollars each, clear profit, with sixty trees to an acre, and that is big enough for anybody." And thereupon this Orange-grower proceeded to show me the accounts of one little orchard of his own, which so greatly exceeded his moderate statement that I shall not give you the figures. After ten years the tree rapidly and steadily increases in fruitfulness; the older trees in the orchards are now bearing, so every owner assured me, very little less than 2,000 Oranges to the

tree. The best cultivators do not prune the tree at all; but in all the orchards willow poles are used to prop up the overlaid branches. Near Los Angeles, at the Mission San Gabriel, there are two large and fine places, those of Mr. Wilson, State Senator from this district, and Mr. Rose. Both are able men, and careful horticulturists. Of Mr. Rose's place, as a model of its kind, I will give you a few particulars, which will bring before your eyes the manner and extent to which fruit culture is practised here. Mr. Rose has 2,000 acres of fine, fair-lying land, well watered, so that he can irrigate the whole of it. 1,200 acres are under fence, and in cultivation and pasture. He raises, as field crops, Barley, Wheat, and Oats, and keeps a large range for a valuable herd of mares and colts. His orchard consists of 400 young but good bearing Orange trees, 4,000 not bearing, and 2,000 more now being planted; 500 Lemons, of which 50 are in bearing; 135,000 Vines, from which he made 100,000 gallons of white wine and 3,000 gallons of brandy, last year; 350 English Walnuts, 150 Almonds; and the place contains besides, in considerable quantities, Apples, Pears, Peaches, Apricots, Nectarines, Pomegranates, Figs, Spanish Chestnuts, and Olives. He mentioned to me, as part of his last year's crop, 250,000 Oranges, 50,000 Lemons, 25,000 lbs. of Walnuts, &c. He thinks his success due to deep and thorough cultivation, and regular irrigation. He irrigates all his trees once in six weeks, and ploughs or hoes after every irrigation. I did not see a single weed or bunch of grass in all his orchards, and such clean culture is very pleasant to the eye. He has on his place wine-presses, and a still-house for making brandy. One man on his place, and with his system, can care for twenty acres of orchard, and one man can pick 5,000 Oranges in a day. He buys the shooks and makes his own boxes, and also makes his own wine-casks. His regular force consists of fifteen men, of whom the ploughmen are Indians; some others are Chinese.

**Mildness of the Season—Caution.**—Notwithstanding what one daily hears of the mildness of the season and the stereotyped evidences of it chronicled in the daily press—erratic Rose blooms, precocious Primroses, and budding Hawthorns, we must ask our friends not to be lulled into false security, but, on the contrary, to be more than ordinarily on their guard. If the season has been somewhat remarkable for its mildness, it has been specially so for its almost continuous and unprecedented rainfall. A cold summer, wet, sunless autumn, and a drenching winter are badly calculated to place our fruit trees in a condition fit to bring them safely through, in the event of being subjected to the action of severe frost. Notwithstanding present appearances, such a contingency is by no means improbable; on the contrary, experience teaches us that heavy and continuous rainfalls are not unfrequently succeeded by frosts—sudden, sharp, and destructive. Should such occur during the present or succeeding months, we dread the results; for assuredly never was the condition of our fruit trees, &c., less calculated to resist their effects. Green, unripe wood, gorged vessels, sap in motion, and roots in soil cold and drenched to saturation, go to make up the conditions which render tree or plant less capable of resisting the destructive agency of frost. It, therefore, behoves all to be on their guard, and to take measures accordingly, more than if the winter was of an opposite character, calculated to retard rather than promote vegetation. Dryness at the root and dryness of the exposed parts of the more tender wall trees should be secured as much as possible. Any measures calculated to retard the bloom are also worthy of consideration, as its premature development is just one of those newspaper evidences of the mildness of seasons which the practical man and fruit grower has reason to regard with anything but complacency. Though, of course, hopeful that mildness will continue to be the character of what remains of winter, as also of the spring that is to follow, it can do no harm to look ahead, and let the watchword be “Caution.”—*Irish Farmers' Gazette.*

#### NOTES AND QUESTIONS ON THE FRUIT GARDEN.

**Apples in Barrels.**—With reference to the packing of the Apples now sent from the other side of the Atlantic to our markets, we are informed that it is very important that the barrels be headed up on a dry and cool day, and not when the atmosphere is damp. Apples keep better in somewhat loose than in very tight barrels, better when the barrels are laid on their sides than when standing upright, and better in a cool dry cellar than elsewhere.

**Rag Manure for Fruit Trees.**—Monsieur M. E. Jacquemyns, who has for many years endeavoured to render fertile the sterile lands of Campine, has sent us the following communication on the subject of the best manure to be employed at the time of planting fruit trees. “You have seen,” he says, “my fruit trees in Campine, on recently cleared heath, the soil of which is far inferior to that of any other part of my property. The trees have been planted without farm manure, but each tree received at the time of planting from 20 to 24 lbs. of woollen rags, a manure very rich in azote. This kind of fertiliser produced excellent results, and will be welcomed by all who are about to plant in localities where farm manure is scarce.”—*Bull. Gen. P. Agric. Cult.*

## THE LIBRARY.

### THE HANDY BOOK OF FRUIT CULTURE UNDER GLASS.\*

THOSE who have read Mr. Thomson's “Handy Book of the Flower Garden” will be able to anticipate the character of the work now before us. But this does more for the fruit grower than that did for the lover of flowers. The author truly says in his preface that most of the fruits treated of have either been included in larger works or have formed the subject of separate observations; but the object now is to furnish a book of moderate size on all points necessary to the successful cultivation and forcing of hardy fruits. While the information given cannot fail to be useful to all, the author has chiefly had in view the requirements of young gardeners entering on their professional career and inexperienced amateurs wishing to superintend their own fruit houses and to manage them so as to obtain from them the most speedy and certain return with a minimum amount of labour and cost. In order to do this effectively, Mr. Thomson begins at the beginning and goes through to the end. Thus in 80 pages the whole matter of Vine growing is discussed from first to last; from the choice of a site to the consumption or transportation of the fruit, Mr. Thomson never leaves his pupils to a doubtful course.

In advertisements we often read of strong canes for fruiting from 10s. 6d. to 15s. each; good planting Vines 3s. 6d. The inference to the inexperienced is that almost any Vines will do for planting, and the idea of special and careful preparation for this object has been too much ignored. Let us hear what Mr. Thomson says on this subject.

#### PREPARING YOUNG VINES FOR PLANTING.

To prepare one-year-old Vines for planting, about the middle of January select the necessary number of strong prominent buds from Vines that have thoroughly well and early ripened their wood. Cut away the wood to within a quarter of an inch on the upper side of the bud, and that on the underside to within an inch—making clean cuts with a sharp knife. The buds are thus ready for insertion. Take the required number of 4-inch rather deep pots, drain them well, and fill them up rather firmly with three parts light fibry loam, and one part of finely-sifted, well-decomposed leaf-mould. Make a hole in the centre of each to receive the buds, into which they are to be inserted, and surrounded with a little propagating sand. Cover them to the very tips of the buds. When they are put in, place them in a house slightly warmer than a common greenhouse; and if the soil is moist, do not water them for a week. The first week of February remove them to some house or pit where they can be plunged near the glass in a bottom heat of 80 to 85°, with a night temperature of 55 to 60°. Keep them steadily and moderately moist, and they will soon burst their buds; and as they begin to develop their leaves, raise the temperature 5°, and let it run up 10° more with sun-heat by day before giving air. The process of leaf-development and the formation of roots will be nearly simultaneous, although generally leaves slightly precede the roots. Consequently, after they have formed two or three small leaves, they halt in growth till the roots have fairly commenced their work. At this stage see that they do not become over dry. Just keep the soil moist, but not wet, and always with water at a temperature of 80°. As soon as the young roots reach the sides of the pots and down to the drainage, raise them by degrees out of the plunging material and stand them on its surface. Range the night temperature at 65° at night, with 10° or 15° more by day with sun. As soon as they have pretty well filled their pots with roots, and begun to grow away freely with stronger and more transparent-like growth, shift them into larger pots—7 and 8 inch pots are large enough for growing Vines into an excellent condition for planting; for far more depends on the character of the roots they make, and the ripeness and soundness of the canes, than on mere bulk of growth.

There is nothing that so much influences the character of the roots that young Vines make after this stage as the nature of the soil, and the position in which they are grown. Take one of these young Vines now ready for a shift out of a 4-inch pot; let an 8 or 10-inch pot be drained, as is so often the case, with a few large pieces of broken tiles or even bricks put into the bottom of the pot in a careless manner; put them in a soil of rather tenacious character, and add to it a large proportion of rotten manure; plunge them in bottom heat, and grow them crowded together far from the glass, and what

\* “The Handy Book of Fruit Culture under Glass.” By David Thomson of Drumlanrig. Blackwood & Sons, Edinburgh.

is the result? The soil, instead of being thoroughly filled with well-ripened fibry roots at the end of the season, is only occupied by a comparatively few long fleshy roots, which never ripen properly, and die in the winter. The cane itself is not of that compact, short-jointed, well-ripened stamp which alone is a sure indication that all is right. When such a Vine is shaken out in spring to be planted, it is found comparatively rootless, and in every way inferior.

Take the same young Vine and shift it into a well and carefully drained pot not larger than 8 inches, in a compost composed of a good, sound, rather light loam, having a fourth part of thoroughly-decomposed manure, and a sprinkling of bone-meal and sand mixed with it. Pot firmly, and stand it on the surface of the plunging material, or even on a shelf or the floor of a light house, and grow it the whole time without bottom heat, and the result is a potful of beautifully well-ripened fibrous roots, that keep fresh through the winter in such quantity that when they are shaken out of the soil for planting in spring, the pot appears to have been full of roots and nothing else. There is no comparison between these two descriptions of Vines for planting. All is in favour of the latter, of course. Avoid, therefore, in growing young Vines, badly-drained pots, a close retentive soil, and *bottom heat after they are well rooted*.

The italics are ours. We believe hundreds of Vines have been ruined by an excess of bottom heat. We once received a batch grown over the pipes in a Pinery. Most of these died when planted out the following spring. Opening the book at p. 193 we find the following sensible instruction upon—

#### PRUNING AND PINCHING FIGS.

When the trees have shed their leaves, they should be kept comparatively dry at the root all winter. What pruning is necessary should be performed in winter when they are at rest. Very little pruning will, however, suffice, if their summer growths have been produced and regulated according to the foregoing directions. There will be the main stems, with the cordon branches that were established the previous year, when the young plants were in pots,—now extending right and left to about 4 feet,—with their lateral growths at regular intervals, and the cordon growths produced this season. My practice in pruning Figs thus trained horizontally, and from which two crops are to be annually ripened, differs somewhat from that usually pursued, and may be described as a mixture of Vine pruning on the close spur system and ordinary Peach pruning. The first crop of fruit is produced from the young wood of the previous summer's growth; and the second, which ripens generally in September and October, from the young growths of the same summer, and which are produced contemporaneously with the first crop of fruit on the previous season's growth. In order to have a regular crop over all the tree at these two seasons this habit must be borne in mind, and the pruning performed accordingly, so that the trees may be regularly furnished with these two sets of growth.

The shoots that bear the early fruit are only allowed to form about two leaves. Each branch, therefore, bears a double crop before it is cut back—an autumn and a spring one. It then gives place to a young shoot, and so on for ever. The result is highly satisfactory as regards fine fruit, and the orderly appearance of the trees. There is no crowding, no confusion, and, with good management, the certainty of a regular crop. We trust that we have said enough to show what may be expected to be found in this truly useful book, which is illustrated by woodcuts when necessary, and contains a good calendar for every month in the year, together with a few piquant observations on heating by hot water.

#### GROTESQUE ANIMALS.\*

THERE is a certain irresistible charm in the wildest phantasies of great artists. The villa-studio of Raphael, close beneath the walls of Rome, with the walls of its chambers scrawled all over with the holiday aberrations of a pencil, every touch of which is immortal, is one of the shrieks of modern Rome most sought and most enjoyed by enthusiastic tourists. The caricatures dashed off by other great masters, Rubens, Rembrandt, and even Michael Angelo himself—who was not ashamed to descend from the *terribilis via* on rare occasions, and allow his pencil to indulge in trenchant sarcasm, or even playful gambols—are always full of that kind of fascination which genius alone can impart; and each grotesque, after its kind, is as thoroughly enjoyed by true connoisseurs as the grander works of the artist. Only a few years ago Mr. Lear, an eminent landscape painter, and a

man of real genius, took the town by storm with a "Book of Nonsense," which was beyond doubt the popular book of the season, and gave rise to a perfect deluge of imitators. Now we have Mr. E. W. Cooke, the gifted marine painter, whose pictures have formed a leading feature in all recent exhibitions of the Royal Academy, coming out in a blaze of exuberant fancy with *his* book of clever nonsense, and of science turned inside out, a work which he entitles, "Grotesque Animals." The possibility of the existences of these creatures of his fancy he evidently wishes us to indulge in, as things that might be, he himself playfully gives in the supposition that their entity or nonentity may be reasonably asserted or disputed, according to the philosophical bias of the disputants. It is in that happily placed frame of mind upon the subject that he has placed the following lines upon his title-page.

These oddities, from fancy drawn,

May surely raise the question,

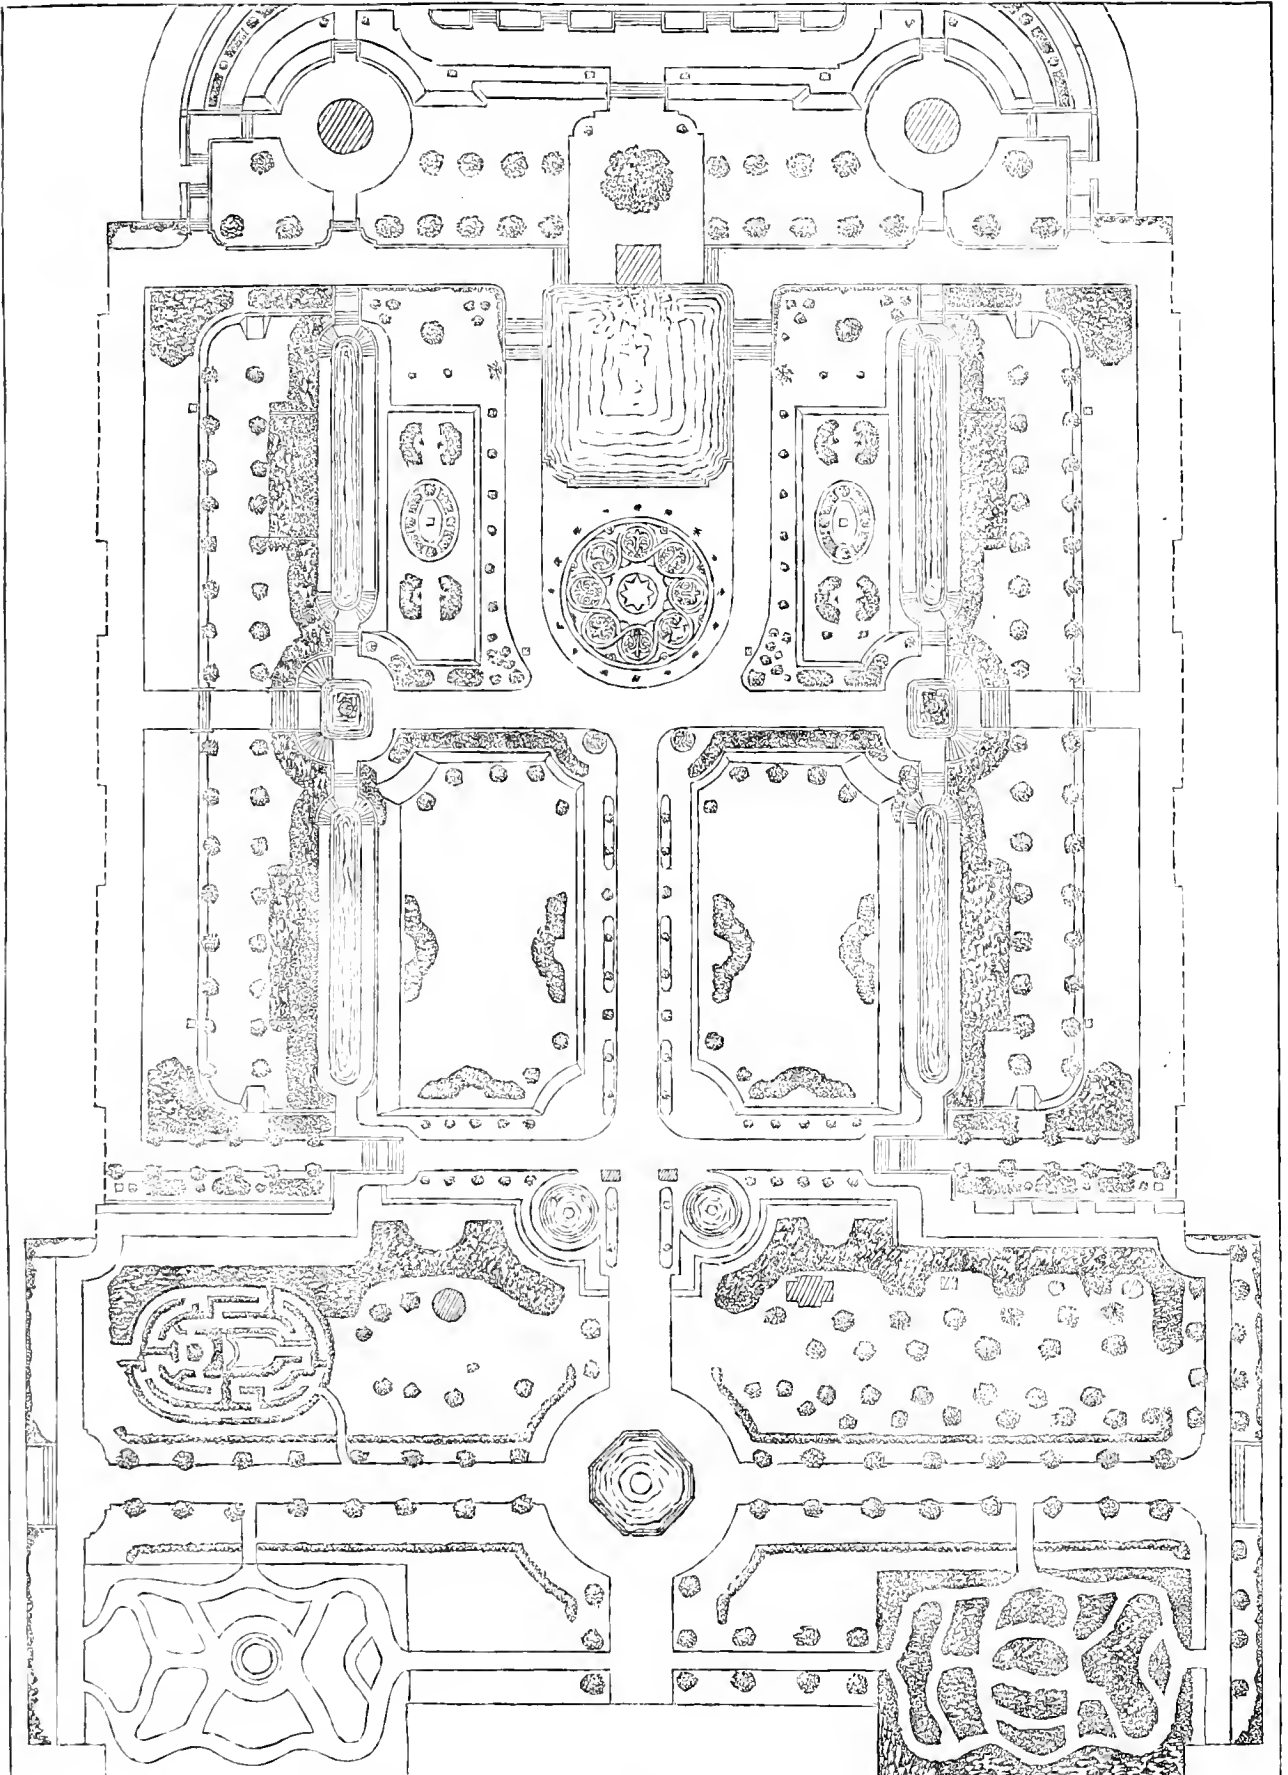

Will Darwin say—by chance they're formed,  
Or natural selection?

Some of the combinations of form are exceedingly humorous, and have that smack and flavour which only genius and fancy combined can produce. The ammonite shell, for instance, of which the form of the ancient inhabitant is now unknown to science, is supposed by the artist to have been the dwelling of the crested Cocotoo! whose head is seen emerging quite naturally from the opening of the shell. Inasmuch as chickens live for a time in shells, and afterwards leave them, this is not a very far-fetched idea. This shell bird is supposed by Mr. Cooke to have been a monopede—a deduction arrived at by way of the well-known fact that the inhabitants of many kinds of recent shells achieve locomotion by means of a single "propeller," and this shelly-birdy creature is, therefore, by an admissible process of reasoning, made to stand upon a single leg—*en bene! se non e vero e ben trovato*. Half a hundred such fancies—one more curious and ingenious than another, follow each other with a fecundity of invention that is perfectly astounding. One is reminded, by the felicity of the dovetailing, of the remark of one of the great physiologists and naturalists of the age, as quoted by the author of these artistic phantasmagoria—"How all the parts of the animal kingdom fit each other." This had, indeed, been instinctively felt long anterior to the year of grace 1873—in the celebrated "Chronicle of Nuremberg," printed by the ingenious artist, Koburger, in 1493. There are in that ponderous volume fancies depicted by the clever gravers of contemporary artists, almost as fantastic, but not so learned as those wrought out by the gifted pencil of Mr. Cooke. Following the verbal pictures of Pliny, St. Augustine, Marco Polo, and Mandeville, we have in this quaint old volume the verbal descriptions reduced to positive forms by very realistic pencils. The Cynocephali or dog-faced apes, for instance, are metamorphosed into well-formed wild men, with positive dogs' heads. The account of a large-eared race of North Eastern Asia is turned to account by making these organs resemble those of lop-eared rabbits, but being made big enough to serve as a mantle to wrap about the body (*aves tam magnas habent ut contegant totum corpus*). But in these old-world fable pictures there is little of that rich humour and playfulness which distinguishes Mr. Cooke's inventive series, to which we heartily wish a favourable reception and just appreciation by the public, though we almost fear they are a shade too clever for those not rather deeply versed in the mysteries of natural science. To those who are, the book will form a fanciful treat of no ordinary kind.

#### HORTICULTURAL GARDENS, SOUTH KENSINGTON.

IN pursuance of our wish to publish in THE GARDEN plans of all our notable gardens, we this week present one of the Kensington Garden of the Royal Horticultural Society. Utterly opposed as we are to this style of garden, it need hardly be said that the plan is not offered for admiration or imitation, but simply as one of a series showing our gardens as they are. Our plan, taken from the ground specially for THE GARDEN, shows all the latest alterations. These chiefly consist of modifications as to the show-grounds at the south end of the garden and of the abolition of some of the panelled gardens which "cut up" the garden so much. By these changes the aspect of the place is somewhat improved here and there, but the general design is still much too complicated. This garden, which has perhaps been more censured than any public garden ever created, affords a good example of the mischief sometimes wrought by what is called a "nice-looking plan." The plan of the garden, as originally published, looked pretty on paper, and writers describing it, without knowing the very great difference between a plan wrought out on the

\* Grotesque Animals: Invented, drawn, and described by E. W. Cooke, R.A.

NEW PLAN OF THE ROYAL HORTICULTURAL GARDENS, SOUTH KENSINGTON.

ground and one on paper, were eloquent upon it as "full of rich and carefully wrought-out detail." Alas! it proved when carried out rich in nearly everything that was wrong in garden design, and so cut up with details, so devoid of anything like what we understand as breadth and repose, that it was difficult to imagine oneself in a garden at all. Let it long be a caution to all who have to design a garden, that even where the style of gardening is geometrical of the most pronounced type, the necessity for breadth and repose is as potent as in gardens in the natural style, and that to dot about "panel gardens," and mazes, and small ponds, and hedges, &c., almost as thickly as they can be placed over the surface is a blunder unworthy of even an amateur who makes a first attempt at laying out a garden.

#### THE DESCENT OF THE SAP.

WE have received the following communication from one of our correspondents, requesting information as to the cause and nature of the descent of the sap in autumn:—

"I and a few horticultural friends have lately been discussing that highly interesting subject, the descent of the sap at the fall of the leaf. As is usual a difference of opinion existed amongst us, and several expressed a desire to know if the question had been settled by scientific authority, and if so, by whom."

The inquiry is a very fair one at this time, for men's minds are shaking off the old received opinions on the subject, and the new ones have not yet got completely settled. Six or seven years ago to such an enquiry the reply would have been that the sap ascended in the vessels of the cambium next the wood and descended in those next the bark. Mr. Herbert Spencer, however, in a paper read to the Linnean Society in 1866 (*Trans. Lin. Soc.* XXV. 405) upset this view completely. By a series of beautiful experiments he showed that there was only one set of vessels, and that consequently there could be no circulation. There might be a certain amount of swaying backwards and forwards like a tide, but nothing of the nature of a circling flow from the roots to the leaves and back again. His proof of this left nothing to be desired, but he set himself to account for the descending sap, and there, although equally ingenious, he was less happy in his argument—and for a very good reason—for it seems very questionable if there be really such a thing as descending sap. As Mr. Spencer pointed out, there may be a strain on a bent branch which will close the vessels for a time, as the veins over our knuckles are closed by pressure when we shut our hand, and the fluid in them may be forced back; but that a true continuous descent of the sap ever takes place is yet to be proved. We know that we can see something like circulation going on in the cellular tissues of certain plants; but this appears to be something different and distinct from the general rise of sap from the root to the leaves, and has at all times been generally regarded as a special and collateral phenomenon.

Professor W. McNab, following up the thread of Mr. Herbert Spencer's observations, about two years ago, made some interesting experiments, which we strongly recommend to the perusal of our correspondent. Speaking from memory, the result of Professor McNab's numerous experiments was, that in no instance could he discover the sap descending. It was always on the ascent, and depended on the presence of the leaves. If they were cut off, and in proportion as they were cut off, the flow of sap ceased. Our correspondent will see that he has an interesting and not yet exhausted field of inquiry before him.

The conclusion at which we individually have arrived is, that the leaves and tender covering of the twigs (what may be called the whole true skin of the tree), acts as a combination of suckers (perhaps everystoma, and the reader will find them on the skin of the twigs as well as on the leaves, is one), which under the influence of the air and temperature act as a pump, and draw up the sap that enters by the roots. As is perfectly shown by Mr. Herbert Spencer, a portion of the sap penetrates through the walls of the vessels, and deposits itself as wood around them; another portion is, no doubt, evaporated through the leaves. Of course, when the vessels are full, no more can enter, but the fuller they are the

more will be squeezed through the walls, and the more wood formed. When night comes and the influence of the day is gone, when, as it were, the pump will not draw, the flow of sap ceases, and it may fall back in the vessels; at all events, as deposition goes on, the quantity in them will decrease. When the leaves fall off in autumn, the pump has, as it were, lost its suckers, and the ascent of sap all but ceases. It does not descend, it only ceases to ascend. Professor McNab found, indeed, that when he had cut off all the leaves, there was still a feeble ascent; this, according to our view, is produced by the stomata in the bark covering the twigs, and an examination of the annual rings of ligneous deposit in a stem or branch shows that there is a certain amount of flow of sap and deposit going on in winter as well as in summer, although too slight to be capable of direct observation. Do not let it be supposed that we imagine that this rude comparison of the machinery of the flow of sap in a tree to that of a pump by any means explains the whole mystery of its rise and flow. It is at best only a clumsy attempt to illustrate one part of the process; but so far as it goes, it is consistent with fact, and if it be a true explanation, there can be no *descent* of the sap in autumn. If our correspondent takes a different view, it is for him to prove that there is, not by hypothesis or theory, but, as has been done on the other side, by actual experiment.

A. M.

METHINKS I see great Diocletian walk  
In the Salonian Garden's noble shade,  
Which by his own imperial hands was made:  
I see him smile (methinks) as he does talk  
With the ambassadors, who come in vain  
To entice him to a throne again.

"If I, my friends (said he) should to you show,  
All the delights which in these gardens grow;  
'Tis likelier much that you should with me stay,  
Than 'tis that you should carry me away:  
And trust me not, my friends, if ev'ry day  
I walk not here with more delight,  
Than ever, after the most happy fight,  
In triumph, to the Capitol, I rode,  
To thank the gods, and to be thought myself almost a god."

COWLEY.

**A City of Magnificent Perspectives.**—Stand at the head of Sixteenth-street, Washington, and the eye sweeps down nearly two miles over a paved and well planted street to the very portals of the White House; stand at the War and Navy departments, looking west through F and G streets, and the waters of the Potomac are seen glistening in the sun; stand at the foot of Vermont-avenue, at Lafayette-square, and the eye has an uninterrupted view of three miles to the Harvard University; stand on the portico of the White House, looking out New York-avenue, and the eye sweeps uninterruptedly a distance of five miles to the north-west, beyond Glenwood Cemetery; stand on high ground in the city at the corner of Massachusetts-avenue and Twelfth-street, and the eye ranges over five miles of broad street on towards the south-east, and two miles on towards Kalorama Heights in the north-west; where the President's private mansion and the great public park ought to and probably will be.—*Times*.

**A Persian Eden.**—The remembrance of a garden which had charmed me as we passed hurriedly through it two days before, enticed me back to Kazeroon. This garden was 2 or 3 acres in extent, and surrounded by walls high enough to keep out intruders and ensure privacy; within them were the coolest shade, the most brilliant colouring, the sweetest of perfumes, and the softest of nature's music. Tall, graceful Date Palms waved their feathery branches aloft in the bluest of skies, gently fanning dark still groves of Orange and Lemon trees laden with golden fruit; below and amongst them were thickets of Pomegranate bushes, bright with their rich scarlet waxen flowers, and endless quantities of blooming Roses and Jasmine; the soft balmy air was luxuriously redolent with fragrant odours of Orange blossom and attar, and filled with the sweet warbling of nightingales, and the soft cooing of turtle doves. In the centre, and approached by grassy avenues and long bowers of sweet Lime trees, stood a ruined kiosk and a broken fountain; there, in the checkered shade, my carpet was spread and my bed stretched; for, once within these fairy walls, why should I leave them? Was not this a spot where wintry cold, burning sun, dreary desert, the whole world outside, might be forgotten? Was there not here the beauty, the quiet, the contentment of Paradise? What was wanting? The sympathetic love of the fair Eve, whom most men search for, but few find; whom the most fortunate find in time, the most unfortunate, too late.  
—A. H. Mouney.

## THE ARBORETUM.

## HARDY TREES AND SHRUBS.

BY GEORGE GORDON, A.L.S.

THE WOOLLY-LEAVED NEPAUL MAPLE (*ACER VILLOSUM*).

THIS forms a splendid large deciduous tree 60 to 80 feet high, with the habit and general appearance of the common Sycamore. It is a native of Upper Nepal and the high Alps near the line of perpetual snow in Kamaoon and Sirmore. It was first introduced in 1845 by Messrs. Osborn, of Fulham. The leaves are large, somewhat angularly five-lobed, palmately veined, cordate at the base, set on long footstalks, and when young, like the buds and petioles, thickly coated all over with a silky down; but when full grown, they are smooth and deep green above, and densely covered with rusty coloured soft hairs beneath. The lobes are ovate with acute points, entire on the edges, and the three outer ones much the largest. The flowers are pale yellow, with the petals bearded at the apex and fragrant; they are produced in long, slender, lateral, nodding, simple spike-like racemes in great abundance in May. The fruit or keys are rather large and villous, with thick

*Acer villosum.*

carpels and ample cultriform, crenelated wings but slightly diverging, and in long pendulous simple racemes. The length of a full-sized leaf is 12 inches, including the footstalk, which is frequently 5 or 6 inches long, and the breadth is 8 inches.

## ASA GRAY ON GEOGRAPHICAL DISTRIBUTION.

THE remarkable facts in regard to the Eastern American and Asiatic floras, which these speculations were to explain, have since increased in number, more especially through the admirable collections of Dr. Maximowicz in Japan and adjacent countries, and the critical comparisons he has made and is still engaged upon. I am bound to state that in a recent general work\* by a distinguished botanist, Professor Grisebach of Gottingen, these facts have been emptied of all special significance, and the relations between the Japanese and the Atlantic United States floras declared to be no more intimate than might be expected from the situation, climate, and present opportunity of interchange. This extraordinary conclusion is reached by regarding as distinct species all the plants common to both countries between which any differences have been discerned, although such differences would probably count for little if the two inhabited the same country, thus transferring many of my list of identical to that of representative species, and then by simply eliminating from consideration the whole array of representative species, *i.e.*, all cases in which the Japanese and the American plant are not exactly alike. As if, by pronouncing the cabalistic word

species, the question were settled, or rather the greater part of it remanded out of the domain of science; as if, while complete identity of forms implies community of region, anything short of it carries no presumption of the kind; so leaving all these singular duplicates to be wondered at, indeed, but wholly beyond the reach of inquiry. Now the only known cause of such likeness is inheritance; and as all transmission of likeness is with some difference in individuals, and as changed conditions have resulted, as is well known, in very considerable differences, it seems to me that if the high antiquity of our actual vegetation could be rendered probable, not to say certain, and the former habitation of any of our species, or of very near relatives of them in high northern regions could be ascertained, my whole case would be made out. The needful facts, of which I was ignorant when my essay was published, have now been for some years made known, thanks mainly to the researches of Heer upon ample collections of arctic fossil plants. These are confirmed and extended through new investigations by Heer and Lesquereux, the results of which have been indicated to me by the latter. The *Taxodium*, which everywhere abounds in the miocene formations in Europe, has been specifically identified, first by Goepfert, then by Heer, with our common Cypress of the Southern States. It has been found fossil in Spitzbergen, Greenland, and Alaska, in the latter country along with the remains of another form, distinguishable, but very like the common species; and this has been identified by Lesquereux in the miocene of the Rocky Mountains. So there is one species of tree which has come down essentially unchanged from the tertiary period, which for a long while inhabited both Europe and North America, and also at some part of the period the region which geographically connects the two (once doubtless much more closely than now), but has survived only in the Atlantic United States and Mexico. The same *Sequoia* which abounds in the same miocene formations in Northern Europe has been abundantly found in those of Iceland, Spitzbergen, Greenland, Mackenzie river, and Alaska. It is named *S. Langsdorffii*, but is pronounced to be very much like *S. sempervirens*, our living Redwood of the Californian coast, and to be the ancient representative of it. Fossil specimens of a similar, if not the same, species have been recently detected in the Rocky Mountains by Hayden, and determined by our eminent palaeontological botanist, Lesquereux; and he assures me that he has the common Redwood itself from Oregon, in a deposit of tertiary age. Another *Sequoia* (*S. Sternbergii*), discovered in miocene deposits in Greenland, is pronounced to be the representative of *S. gigantea*, the big tree of the Californian Sierra. If the *Taxodium* of tertiary time in Europe and throughout the arctic regions is the ancestor of our present bald Cypress, which is assumed in regarding them as specifically identical, then I think we may, with our present light, fairly assume that the two Redwoods of California are the direct or collateral descendants of the two ancient species which so closely resemble them.

The forests of the arctic zone in tertiary times contained at least three other species of *Sequoia*, as determined by their remains, one of which, from Spitzbergen, also much resembles the common Redwood of California. Another, "which appears to have been the commonest coniferous tree on Disco," was common in England and some other parts of Europe. So the *Sequoias*, now remarkable for their restricted station and numbers, as well as for their extraordinary size, are of an ancient stock; their ancestors and kindred formed a large part of the forests which flourished throughout the polar regions, now desolate and ice-clad, and which extended into low latitudes in Europe. On this continent one species at least had reached to the vicinity of its present habitat before the glaciation of the region. Among the fossil specimens already found in California, but which our trustworthy palaeontological botanist has not yet had time to examine, we may expect to find evidence of the early arrival of these two Redwoods upon the ground which they now, after much vicissitude, scantily occupy. Differences of climate, or circumstances of migration, or both, must have determined the survival of *Sequoia* upon the Pacific, and of *Taxodium* upon the Atlantic coast, and still the Redwoods will not stand in the east, nor could our *Taxodium* find a congenial station in California. As to the remaining near relative of *Sequoia*, the Chinese *Glyptostrobus*, a species of it, and its veritable representative, was contemporaneous with *Sequoia* and *Taxodium*, not only in temperate Europe, but throughout the arctic regions from Greenland to Alaska. Very similar would seem to have been the fate of a more familiar gymnospermous tree, the *Ginkgo* or *Salisburia*. It is now indigenous to Japan only. Its ancestor, as we may fairly call it, since, according to Heer, "it corresponds so entirely with the living species that it can scarcely be separated from it," once inhabited northern Europe and the whole arctic region round to Alaska, and had even a representative further south in our Rocky Mountain district. For some reason, this and *Glyptostrobus* survived only on the shores of Eastern Asia. *Libocedrus*, on the other hand, appears to have cast in

\* Die Vegetation der Erde nach ihrer klimatischen Anordnung, 1871.

its lot with the Sequoias. Two species, according to Heer, were with them in Spitzbergen. Of the two now living, *L. decurrens*—the Incense Cedar—is one of the noblest associates of the present Redwoods; the other is far south in the Andes of Chili. The genealogy of the Torreya is more obscure, yet it is not unlikely that the Yew-like trees, named Taxites, which flourished with the Sequoias in the tertiary arctic forests, are the remote ancestors of the three species of Torreya, now severally in Florida, in California, and in Japan. As to the Pines and Firs, these were more numerous associated with the ancient Sequoias of the polar forests than with their present representatives, but in different species, apparently more like those of eastern than of western North America. They must have encircled the polar zone then, as they encircle the present temperate zone now.

I must refrain from all enumeration of the angiospermous or ordinary deciduous trees and shrubs, which are now known by their fossil remains to have flourished throughout the polar regions when Greenland better deserved its name, and enjoyed the present climate of New England and New Jersey. Then Greenland and the rest of the north abounded with Oaks, representing the several groups of species which now inhabit both our eastern and western forest districts; several Poplars, one very like our Balsam Poplar or Balm of Gilead tree; more Beeches than there are now, a Hornbeam, and a Hop Hornbeam, some Burches, a Persimmon, and a Plane tree, near representatives of those of the Old World, at least of Asia, as well as of Atlantic North America, but all wanting in California; one Juglans like the Walnut of the Old World, and another like our black Walnut; two or three Grape Vines, one near our Southern Fox Grape or Muscadine, the other near our Northern Frost Grape; a Tilia very like our Basswood of the Atlantic States only; a Liquidambar; a Magnolia, which recalls our *M. grandiflora*; a Liriodendron, sole representative of our Tulip tree; and a Sassafras, very like the living tree. Most of these, it will be noticed, have their nearest or their only living representatives in the Atlantic States, and when elsewhere, mainly in Eastern Asia. Several of them, or of species like them, have been detected in our tertiary deposits west of the Mississippi by Newberry and Lesquereux. Herbaceous plants, as it happens, are rarely preserved in a fossil state, else they would probably supply additional testimony to the antiquity of our existing vegetation, its wide diffusion over the northern and now frigid zone, and its enforced migrations under changes of climate. Concluding, then, as we must, that our existing vegetation, as a whole, is a continuation of that of the tertiary period, may we suppose that it absolutely originated then? Evidently not. The preceding Cretaceous period has furnished to Carruthers in Europe a fossil fruit like that of the Sequoia gigantea of the famous groves, associated with Pines of the same character as those that accompany the present tree; has furnished to Heer, from Greenland, two more Sequoias, one of them identical with a tertiary species, and one nearly allied to Sequoia Langsdorffii, which in turn is a probable ancestor of the common Californian Redwood; has furnished to Lesquereux, in North America, the remains of another ancient Sequoia; a Glyptostrobus; a Liquidambar which well represents our sweet gum tree; Oaks analogous to living ones; leaves of a Plane tree, which are also in the tertiary, and are scarcely distinguishable from our own *Platanus occidentalis*; of a Magnolia and a Tulip tree; and "of a Sassafras undistinguishable from our living species." I need not continue the enumeration. Suffice it to say that the facts will justify the conclusion which Lesquereux—a very scrupulous investigator—has already announced, "That the essential types of our actual flora are marked in the cretaceous period, and have come to us after passing, without notable changes, through the tertiary formations of our continent."

According to these views, as regards plants at least, the adaptation to successive times and changed conditions has been maintained, not by absolute renewals, but by gradual modifications. I, for one, cannot doubt that the present existing species are the lineal successors of those that garnished the earth in the old time before them, and that they were as well adapted to their surroundings then as those which flourish and bloom around us are to their conditions now. Order and exquisite adaptation did not wait for man's coming, nor were they ever stereotyped. Organic Nature—by which I mean the system and totality of living things, and their adaptation to each other and to the world—with all its apparent and indeed real stability, should be likened, not to the ocean, which varies only by tidal oscillations from a fixed level to which it is always returning, but rather to a river so vast that we can neither discern its shores nor reach its sources, and whose onward flow is not less actual because too slow to be observed by the ephemera which hover over its surface or are borne upon its bosom.

Such ideas as these, though still repugnant to some, and not long since to many, have so possessed the minds of the naturalists of the present day that hardly a discourse can be pronounced or an investi-

gation prosecuted without reference to them. I suppose that the views here taken are little if at all in advance of the average scientific mind of the day. I cannot regard them as less noble than those which they are succeeding.

**Measuring Trees.**—A contributor sends to *The Country Gentleman* the following rule for measuring trees, which, he says, he has tested to his satisfaction:—"A stick of timber is desired, say 50 feet long; select your tree, measure 50 feet in a direct line from the foot of the tree, on as near level ground as possible; now cut a stick the exact height of the observer, and stick it in the ground exactly perpendicular; now let the observer lie flat on his back, his feet against the stick and head in the line of the tree and stick, and look directly over the top of the stick, and where the line of vision strikes the tree will be the length of stick, 50 feet, desired. If the ground is not level, the measure will not be exact, but allowance must be made."

**Effect on the Rainfall on Trees.**—Whatever may be the effect produced on garden and field crops by the enormous rainfall of the past three months, there can be no doubt that our large trees will benefit by it immensely. A real soaking had become for them an absolute necessity, as in many places the soil deep down at the base of the trees was thoroughly dried, and for several years past branches have been dying at a most alarming rate. Worse still, large trees have also died entirely, no doubt starved for want of moisture, the comparatively small amount of rain that has fallen for several years previously having entirely failed to give the ground about the roots that thorough drenching that it has now obtained. Next summer we may reasonably look for a strong growth of young wood, in the case of all kinds of trees, and no doubt, also, the foliage will even, under unfavourable conditions, be retained until a much later period of the year. In some of our parks, gardens, and avenues, we have seen magnificent trees die without being able to assign a reason for such a mishap. How much has drought at the roots had to do in promoting this disaster? Possibly much more than is commonly imagined. When the surface of the soil is either trodden very hard or macadamised over, but a very small amount of the rainfall can possibly reach the roots, and starvation soon ensues.—A. D.

**The Ailantus as a Timber Tree.**—What dimensions the *Ailantus glandulosa* may assume in the southern parts of the kingdom, I know not; but one thing I do know, that it has not been my gratification to see it as a fine timber tree anywhere, especially from where I write, North Lancashire. Being at a gentleman's residence some time ago, and walking round the kitchen garden, I was so struck with what appeared to be a peculiar and beautiful Ash that stood outside the garden wall on the lawn, that I could not resist going to see what species of Fraxinus it really was, its noble deep green pinnated foliage being quite new to me. Guess my surprise on nearing it to find it to be a fine tree of the *Ailantus*—a tree in every sense of the word—a tree that would even tell a tale in a timber-yard, one that would have taken considerable adzing and squaring to prepare it for the sawpit. I had often seen it as a semi-shrub rising above Hollies and Laurels in shrubberies, but never before as a fine stately tree. I know nothing of the nature of its timber, but know that it is a very fast grower; the wood is said to be very close and hard, taking a polish like satin. It will grow in the worst of soils. Why is it not more common?—T. Williams.

#### NOTES AND QUESTIONS ON TREES AND SHRUBS.

**Catalpa syriaca.**—In the garden belonging to Emmanuel College, Cambridge, is a fine old specimen of this tree, with a reclining stem and large spreading head. At 7 feet from the ground the girth of the bole is 8 feet.—J. J. CHATER, Cambridge.

**Large Tulip Tree.**—In the Fellows' garden at Emmanuel College, Cambridge, is a Tulip tree, about 70 feet in height, the branches of which are 15 feet from the ground. The bole, at 2 feet from the ground, is 2½ feet in diameter, and at 14 feet from the ground its circumference is about 6 feet. It is altogether a magnificent specimen of this kind of tree.—J. J. C.

**Neglecting Young Trees.**—I can quite sympathize with your correspondent "A Soldier" (p. 56) as regards the loss of his trees. Some years ago I purchased some dozens of fruit and ornamental trees, and a few of them are now doing pretty well, while others are dead and forgotten. The fact is that planting trees requires a great deal of personal attention, especially in poor soils. I formerly left mine to the care of others; but experience has taught me that newly planted trees require good sized holes, say from 1 foot wide to 4 feet deep, on poor soils like my own, with the addition of some loam and manure, unless the ground has recently been well broken up, two or three spits deep. Although the holes are the size described the trees should be planted near the surface, the roots carefully spread out, so that they get the benefit of the sun, the air, and the rain, and afterwards kept free from weeds for two or three feet round. A digging in the autumn, also, I have found beneficial. If your correspondent directs these little matters personally, I think he will be amply repaid for his trouble.—O. S., Ipswich.

## THE FLOWER GARDEN.

### SUB-TROPICAL GARDENING.

EXPERIENCE has so thoroughly established the possibility of employing subtropical plants out of doors in summer with advantage, that the all-absorbing topic now is, not that such plants will not succeed out of doors, but what kinds shall be planted out next season. In selecting plants for that purpose those only should be decided upon which are of bold growth and ample foliage, plants which stamp their image upon our memory by their individuality of character, and by the beautiful contrasts which they make with their associates, be they in groups or planted as single specimens. I cannot perhaps make myself better understood than by referring to the accompanying illustration, in which are represented several exquisite groups. Prominent in the background is a Palm with charmingly divided leaves; then there is the massive and beautiful Abyssinian *Musa*, which is readily distinguished from all around it. A little behind it rises the great tussock and large feathery plumes of the Pampas Grass, backed up by dark leaved Conifers that not only afford a splendid contrast and serve to render the picture complete, but help to ward off any sudden or destructive gales of wind that may arise. Another type of leafage is seen in the Fan-leaved Palm and the large and deeply-lobed foliage of *Gunnera scabra*, while beautiful *Yuccas* and the long spear-like shoots of Bamboos which appear on the right of the picture make a *tout ensemble* capable of attracting the attention of even the most obtuse lover of nature. It will thus be seen that rich effects may be produced without having recourse to the most tender exotics, which should be kept for ornamenting our stoves.

The endeavour, indeed, to use tender plants so as to produce an effect totally different from that derivable from our ordinary hardy plants led, in the early days of sub-tropical gardening, to the most disastrous results; for not only were many fine leaved plants from stoves killed by their sudden transference from these to the open air, but many plants that had not the slightest claim to be used for such a purpose (except that they came from a tropical country) also met their death at that time from reckless exposure. Thus many failed in their first attempts at sub-tropical gardening, and then condemned the system. It must not be inferred that every stove plant can be induced to become an ornament to our pleasure grounds during summer, even when properly treated, simply because no amount of management will enable some plants to *live* out of the hot damp air of the stove; indeed, some plants which we grow indoors lose all pretensions to beauty in the open garden, and, therefore, should not be used out-of-doors. But why rush to the stove when it is really not at all necessary that stove plants should be employed? To

this fact I wish to direct particular attention, especially that of those who live in the suburbs of large towns. Too often we see shapeless masses of one kind of shrub planted in even *small* gardens, where, had a variety of plants been selected, each remarkable for its beauty of outline or boldness of foliage, they would have formed the framework for a pretty home landscape, whilst amongst them flowering plants, shrubs, and trees might be mixed, and small groups of sub-tropical plants introduced in summer with much advantage. Surely such a style of planting must be better than a mere hedge of Laurel, Yew, or similar common-place shrubs, in front of which run a few straight lines of colour, which, however gay for three or four months, lie bare and blank for the rest of the year. A far greater amount of pleasure is derivable from a garden planted as is here represented than from one in which bedding plants form the chief feature. Our flower gardens, indeed, as a rule, have too much colour in them. Nobody having any pretensions to taste would admire a bouquet, let it contain ever so many rare and choice flowers, if it was not relieved by green leaves and fronds of Ferns. We have plenty of grand hardy plants which would form splendid ornaments in suburban gardens; but, in the meantime, I only wish to say a few words upon the management of tender plants intended for the open air. It is but feasible to imagine that any plant wintered in a high temperature will not grow in the summer if planted in the open air; therefore I prefer inuring such plants as are intended for the sub-tropical garden to the very lowest temperature they will bear during the winter. This gives them such a thorough rest that they wake up with vigour, and produce strong, hardy growth. This system will be found far better than inducing the plants to make their growth indoors, and then hardening them off; for no amount of hardening will render such foliage so robust as that made in the open air.

G.

View in a Sub-tropical Garden.

### Garden Primroses.—

For very early blooming flowers of the most charming character commend me to our

garden Primroses. So early do they flower that in moderately sheltered spots, or during mild seasons, they commence throwing up their pretty blossoms in November, and as long as there are no severe frosts, they will continue to bloom right into the spring. Perhaps none excels in earliness, in richness of colouring, or in abundance of flower the single crimson, its very earliness enabling the plants to form new crowns early in the year, thus maintaining its character. For a sheltered winter garden, or for the banks and dells of a wild garden, or for keeping in countenance the pure white of the Snowdrop, or the rich hue of the *Scilla sibirica*, I know of nothing that can excel this lovely Primrose. I have had that sort as well as seedling forms of it, and other shades of colour, in flower, in a fully exposed situation, and in cold stiff soil, for these past six weeks, and this fact will afford some idea as to what a charming plant it is when in warm, sheltered nooks or borders. It has one drawback, namely, that being so close to the ground, the flowers soon get soiled; but this

may be obviated by the use of a little Cocoa-nut fibre strewn around the plants. Both in the Primrose and in all the hardy Primula tribe, the great cause of early blooming is keeping the plants growing on through the heat of summer, and not permitting them, through drought, to lose their foliage. Thus the blooming crowns are formed early and strong, and there is no weakening of the plant, a result that always follows loss of foliage in this class of hardy perennials. Garden Primroses vary in colour from white to all the shades of yellow, lilac, purple, red, violet, and crimson, and as they produce seed moderately well, are thus capable of considerable increase.—A. D.

#### BANKS *v.* FLAT GROUND FOR SPRING FLOWERS.

For some years I have been advocating elevated base lines for trees, shrubs, and flowers. Even plants bedded out are most effective on banks or rolling ground, though that system of planting has mostly to be carried out on flat beds and borders. There can, however, be no question that raised borders and banks are best for the display of spring flowers and herbaceous plants generally. It is a simple method of doubling, trebling, if need be, their height. Place a Hollyhock on the flat; it runs up say to 10 feet at the most; set it on the summit of a mound 20 feet high, and virtually you have the effect of a Hollyhock 25 or 30 feet in height. This may be thought an extreme way of putting the case. But it is true nevertheless, and the same rule holds good with Phloxes, Peonies, Pentstemons, Dahlias, and all other plants. Again, the raised base lines make us in our arrangements to a great extent independent of the natural stature of plants, and this endows us with marvellous powers in the disposition of colours and forms. For instance—a glorious patch of blue or yellow is wanted at a higher elevation than usual—a mound of earth will enable us to form it of *Alyssum saxatile* or *Myosotis dissitiflora*. The effect of these masses on the same or even on higher levels than the beds of Phloxes, Hollyhocks, &c., would be quite a new feature in the blending of colours and the contrasting of forms. And there is hardly any limit to the extent to which this might be carried.

But in a season like this, unprecedented for its rainfall, another merit belonging to raised banks claims attention. They are drier than flat beds, drain the latter ever so thoroughly. I observe, too, on the slightest frosts that plants are always the most severely nipped that are on or nearest to the level. The elevation, by shooting off the water, likewise keeps out the frost. There are, however, other reasons for the comparative immunity from injury from frost on raised banks. On an even surface, as a rule, the closer to the earth the greater the cold. Little inequalities act like rocks in the ocean. They break the waves up, and cause a dispersion of the monotonous sweep of the cold into little waves of air. Anything that thus disturbs the constant sweep of the cold is likely to prove a pure gain to the plants. Besides there is no difficulty in getting up to 8 or more feet, and above that line the air for some considerable distance is warmer than it is below it. Almost every year I have noticed certain Conifers and shrubs browned up to about 3 feet from the ground; beyond that they are quite green. How often are young *Laurustinus* killed, when old plants, from 6 to 12 feet high, escape? All this speaks in favour of raised base lines for spring and other flowers. Again, by sloping them to the south and west, what an accumulation of warmth we get. Such raised borders absorb the heat infinitely faster than level ones. The sun hits them at an angle that warms the earth, on the principle of compound interest; and even if we must have two faces to such raised banks, beds, or borders, we can plant the eastern and northern sides with hardier plants. Or by planting both sides with the same sort we may enjoy two seasons' beauty instead of one. It is also a singular fact that many rather tender plants will stand the frost better on the cold side of a raised border than on the flat surface of a level one. They are drier, warmer, and subject to fewer alternations of temperature on the former, whence their greater safety. As to the artistic effects, they are all in favour of raised base lines. *Anubrietas*, *Aconites*, *Arabis*, *Forget-me-Nots*, *Violets*, *Snowdrops*, *Squills*, *Anemones*, *Crocuses*, *Tulips*, *Pyrethrums*, annuals, and herbaceous plants in general, how they bulk out, fill the eye, and seem to come to meet one cheerfully and happily from a raised border! *Verbenas* you have

to go and look for them, with head down, to find them on the flat. For these and other reasons that might be given, I would strongly advocate a search for variety this winter where it can be assuredly easily and cheaply found, in the structures of beds, borders, or banks, for spring and other flowers, herbaceous and Alpine plants. D. T. FISH.

#### PLANTS IN BLOOM IN HERTFORDSHIRE.

The following flowers were in bloom in the garden at Drayton-Beauchamp Rectory, Tring, on the 21st inst., viz.:—

<i>Alyssum argenteum</i>	<i>Crocus variegatus fl.</i>	<i>Hepatica triloba</i> and its red and white double-flowered varieties	<i>Primula vulgaris</i> (various) and <i>veris</i>
<i>Arabis blepharophylla</i>	<i>alba velutensis</i>	<i>Iberis scinperflorens</i>	<i>Pulmonaria grandiflora</i>
<i>Anemone blanda</i>	<i>volvans</i>	<i>Jasminum nudiflorum</i>	<i>Scilla sibirica</i>
<i>Anubrietas</i>	<i>volvans</i>	<i>Lanatum</i>	<i>Vesicaria grandiflora</i>
<i>Borago purpurea</i>	<i>Cyclamen Atkinsi</i>	<i>Leucium vertum</i>	<i>Viburnum Tinus</i>
<i>Borago orientalis</i>	<i>Donda</i>	<i>Myosotis dissitiflora</i>	<i>Violet</i>
<i>Calendula officinalis</i>	<i>Epactis</i>	<i>Orobis cyaneus</i>	<i>Horibunda odorata</i> and its double-white variety
<i>Calendula arvensis</i>	<i>Erica herbacea</i>	<i>Petasites alba</i>	<i>Czar Giant</i>
<i>Celsia hymenodes</i>	<i>Erodium</i>	<i>Primula altaica</i>	<i>precox</i> (Russian)
<i>Arcturus</i>	<i>hymenodes</i>	<i>clatior</i> (Japan)	<i>Neapolitana</i> and its variety
<i>Cheiranthus Cheiri</i>	<i>Erantia hymenodes</i>	<i>variabilis</i> (Polynathus) various	<i>Marie Louise</i>
<i>mutabilis</i>	<i>Erysimum helveticum</i>	<i>macrocalyx</i>	<i>suavis</i> and <i>tricolor</i>
<i>Crocus aureus</i>	<i>Galanthus nivalis</i> and its double-flowered variety	<i>Hose in Hose</i>	<i>Alchemilla vulgaris</i>
<i>billoni</i>	<i>Galanthus plicatus</i>		
<i>Dalmations imperati</i>	<i>Helicoborus atrovirens</i>		
<i>luteus</i>	<i>foetidus</i>		
<i>minimus</i>	<i>niger</i>		
<i>nivalis</i>	<i>orientalis</i>		
<i>reticulatus</i>			
<i>suaveolens</i>			
<i>variegatus</i>			

H. HARPER CREWE.

**Plants in Bloom in Warwickshire.**—Yesterday (Jan. 24th), in spite of the frosts of the last few days, the following plants were in bloom in my garden, viz.: *Cydonia japonica*, *Jasminum nudiflorum*, *Gentiana acaulis*, *Tussilago fragrans*, *Chimonanthus fragrans*, *Cyclamen coum*, *Christmas Rose*, *China Rose*, *Laurustinus*, white *Iberis*, double purple *Primrose*, *Violets*, winter *Aconites*, *Snowdrops*, *Crocus*, *Erica herbacea*, and *Primula sinensis*. The *Primula* was planted out in the summer, and has flowered all the winter. *Buttercups* and *Daisies* are in bloom in the fields.—M. J., *Ryton-on-Dunsmore*.

**Cortusa Matthioli.**—I have found this plant most capricious in cultivation, and it is evidently sensitive to slight differences of soil and situation. In the autumn of 1870 I brought home a supply of roots from Mont Cenis, and divided them into three portions, one of which I potted in a mixture of equal parts of peat, loam, and sand; a second I planted out in my herbaceous border, and the remainder in a border of peat, partly under the shelter of American plants. The potted specimens grew luxuriously, producing an abundance of large leaves, but failed to throw up a single flower-scape. The patch planted in the ordinary soil of the herbaceous border gradually dwindled away, making but little growth, and no flower-scapes. The patch in the peat border has mended admirably, growing and flowering with the greatest luxuriance, and ripened a good crop of seed. It evidently requires plenty of root-room, a little shade, and a light, peaty, rather moist soil. The original plants were growing at the bottom of a moist ravine, under the shade of a low thicket.—GEO. MAW, F.L.S.

#### NOTES AND QUESTIONS ON THE FLOWER GARDEN.

**Primroses.**—In looking over thousands of Primroses in the woods, the only departures from the normal condition which I saw were two—one a perfectly circular flower fringed round the margin, the other never opens its flowers wide, and they never expand beyond the half-blown state. I shall be curious to know if these two forms are permanent. There is a wide field open amongst our British Primroses for hybridists, as my good novelty in this family of plants seems bought by the public as soon as they become aware of it.—Wm. ELLIOTT, *Beechmont*.

**Helianthemum vulgare.**—The garden varieties of this lovely native plant are very numerous. I have been turning my attention to variegated conditions of this plant, and find that there is one in the nursery trade. I have found three more, a scarlet variety with an even margin of white; a large leaved variety with double yellow flowers, and with a very broad leaf-margin of yellow; this is a most beautiful plant, and I think the Queen of the *Helianthemums*. It is of robust growth and habit. These are varieties worthy of introduction amongst the choicest collections of hardy variegated plants.—W. E.

## THE KITCHEN GARDEN.

### PARIS MARKET VEGETABLES AND THEIR CULTURE.

BY A PARIS MARKET GARDENER.

(Continued from p. 17.)

#### WILD CHICORY.

This is sown on a hot-bed broadcast, and rather thickly, in January or February. The young leaves are cut as soon as they have grown large enough, and before they have become hard. They are cut at intervals as long as the plant is in demand at market, and then the bed is destroyed. It may be sown in the open air in spring, and will continue to yield until autumn. Then the plants are covered with a good layer of spent manure, into which they send out fresh leaves. These are cut and sold under the name of blanched Chicory. In order to obtain the salad known as *Barbe de Capucin*, wild Chicory is sown in April, in drills 6 or 8 inches apart. In October the plants are taken up and laid in a trench. A bed of good mixed manure is then prepared in a dark cellar. As soon as it heats, the roots of the Chicory are placed in it in bundles, the decayed leaves having been carefully removed. The plants are slightly watered until they begin to sprout; afterwards they are only watered if the leaves appear to droop, as unnecessary watering rots the hearts of the plants. A crop may be gathered in fifteen or twenty days. By keeping up a supply of fresh manure to the bed, sufficient heat may be maintained to continue the production of *Barbe de Capucin* until March or April. In the north they grow a variety with large roots, which, when roasted and ground, are used to mix with coffee. This kind is not cultivated by Parisian market gardeners. The seed is gathered in August from plants of the previous year. The heads must be rubbed in the hands to separate the seed. Where it is grown extensively, the seed is threshed out with a flail. It keeps good for eight years.

#### CURLED CHICORY.

The varieties grown by market gardeners are, first and best, the Rouen, then the De Meaux, and Endive. They are sown in January, February, and March, on a hot-bed of mixed manure, covered with frame and lights. When the temperature of the bed is so high that the hand can hardly endure it, the seed is sown on the layer of rotten manure without being raked over or covered. It will germinate in about twenty-four hours, and as soon as it has sprouted fine soil should be sprinkled over it, the bed being still kept at the same temperature. Another bed is prepared for transplanting the seedlings in which they are placed—400 or 500 plants to each frame. They should be well covered from the night frosts. In a fortnight or three weeks they may be planted out permanently in hot-beds. Air should be given whenever the weather will permit. Tomatoes, nine plants to each frame, or other kinds of Chicory half-grown, may be interplanted amongst them. Chicory that is to be planted out should be gradually hardened by the frequent admission of air to the frames. Twenty-five or thirty plants to each light and three to each cloche will be sufficient. Tomatoes may be interplanted, six or nine to each light and one to each cloche. Planting out of doors should not take place before April, otherwise the plants are liable to run to seed. Tomatoes should only be interplanted when the Chicory plants are half-grown. If Chicory is sown in the open ground in September, the seedlings may be transplanted under frames, and will yield a crop in winter if they are well sheltered from the cold, to which they are very sensitive. All sowings made before June should be on hot-beds; however, after April there is no need to hasten the germination. Sowings in the open ground may commence in June. Seedlings in hot-beds may be planted out in May, care having been taken to harden them off previously by the gradual admission of air to the frames. In fact, by the 15th of May all sowings, plantings, and transplantings of Chicory may be exposed to the open air, and the frames and lights removed from the beds. In June white or Turkish Celery may be interplanted with Chicory in beds from which a crop of Cabbages or white Onions has been gathered.

#### ENDIVE.

The cultivation of Endive is not less important than that of the preceding plant, but it takes place in autumn. It is

sown in a hot-bed, if an early crop is desired; but in open ground it is grown in the same manner as Chicory. It may also be interplanted in beds of Cabbage Lettuce, Roman Lettuce, Celeriac, and Cauliflowers. Crops are gathered in September, October, and November, according to the time of sowing. Curled Chicory and Endive are used for salads; and, as they are more highly esteemed when the leaves are white and tender, they are blanched in the following manner: As soon as the plants are fully grown and the leaves well expanded, a piece of straw is tied around each plant and fastened at the top. The leaves are thus pressed closely together, so that the light cannot reach the heart of the plant, which soon turns white in consequence. When this has taken place the plant is pulled up at once. A method of blanching Chicory by placing an inverted flower-pot over each plant has been proposed. In dry weather this plan answers pretty well, but in damp weather the plants rot off. Besides, in the market they will only have Chicory and Endive which have been tied up as we have described, and which have very green leaves outside and white hearts. In order to obtain seed, some good plants are placed under frames and sheltered from the frost. In March they are transplanted, without breaking the ball, in a warm position. The Chicory plants should not be placed near the Endive, or hybridization will ensue. The stems are cut when the seed is ripe, and tied together in bundles, which are hung from the ceiling to save them from the mice, which are very fond of this seed. It keeps good for seven or eight years.

#### CAULIFLOWERS.

There are three varieties grown—the tender, the half-hardy, and the hardy. In spring the tender kinds, Little Salomon and Lenormand, are grown. When grown in hot-beds, the seed is sown about the 1st of September; but if in cold beds, from the 10th to the 15th. In October they are transplanted into a cold frame, 200 or 300 plants under each light, in a good depth of spent manure. After transplanting they are watered, to settle the soil about the roots. In December they are taken up, the ground is deeply dug, after which the plants are replanted deeply in the same place, and a good covering of spent manure laid on. When the weather is not frosty, air is given; but on the least appearance of frost they should be covered with mats or litter. Cauliflowers may be planted in hot-beds in January or February. If there are no Carrots in the bed, six Cauliflowers may be planted under each light; but if there are Carrots, the number of Cauliflowers to each light should be reduced to four. Some market-gardeners plant Cauliflowers on old hot-beds, and interplant George or Gotte Lettuces; but this is a matter of individual taste or fancy. When the Cauliflower plants have attained sufficient strength to do without the frames, these are removed; and should there be a return of frost, the plants should be protected at night by mats placed on cords, which are fastened to stakes driven into the corners of the beds. Cauliflowers which have been interplanted among Cabbage Lettuce and Roman Lettuce in a cold frame may be transplanted in the open air in March, either among sowings of Carrots and Radishes, or interplanted among other vegetables. All the Cauliflowers sown in September come in among the early crops in spring. They may also be planted in the Melon trenches and on spent manure in July. The variety called half-hardy is sown under cloches in November, transplanted under frames or cloches in December, and planted out in April. Monthly sowings are also made from January to June. This plant requires a good deal of attention. As soon as the flower-buds appear, they must be covered with leaves plucked from the parent plant, and looked after daily, as they are prized in proportion to the whiteness of the heads. They require constant watering for two months at least; and all caterpillars, snails, slugs, and earwigs, which are very destructive to this plant, should be destroyed. Cauliflowers should be cut as soon as the flower shows a tendency to expand. Plants sown in September and planted out in hot-beds will yield a crop in May, and in June if planted out in cold-beds; but if planted out in the open air, not till July. Cauliflowers sown on the 15th October (St. Thérèse) come in in July, those sown in January and February are gathered in August, those sown in April and May are cut in September and October, and those sown in June come in in November and December. This last crop is often spoiled by the frosts; in this case the plants

are taken up without breaking the balls, and laid in in a trench under lights covered with mats or dung. No sowings are made between the 15th of June and September. Seed of the tender variety is gathered from the earliest and finest plants; that of the half-hardy kind is obtained in the same way in the middle of the season, and of the hardy kind at the end. The seed-plants are allowed to run to seed, and watered moderately at the root; excess of moisture induces the generation of insects and decay. The seed should be gathered before ripening, and hung up to dry in the shade. It keeps good for five years.

## THE HOUSEHOLD.

### FIR-CONE MUSHROOM.

AGARICUS (AMANITA) STROBILIFORMIS.

This truly magnificent agaric grows generally in Fir plantations, but may sometimes be found in grassy hedgerows under trees; though generally considered a somewhat rare agaric, it has been very abundant during the last autumn. It may be known by its almost pure white colour (slightly inclined to buff), its large patches on the pileus resembling in shape the scales of Fir cones, and its thick, solid, compact flesh and

Agaricus (Amanita) strobiliformis (Fir-cone Mushroom); generally amongst Firs; colour, white or pale buff; size, 6 inches diameter, and 6 inches high. With section and spores enlarged 700 diameters.

stem, and large, well-developed annulus. It is closely allied to *Agaricus rubescens*, and the methods of cooking this species will well apply to *A. strobiliformis*.

**MODES OF COOKING THE AGARICUS STROBILIFORMIS.**—It may be toasted, boiled, or stewed in the ordinary way.

**FRIED STROBILIFORMIS.**—Place the full-grown agarics in water for ten minutes, then drain, and having removed the warty skin, fry with butter, pepper, and salt. The ketchup made from *Agaricus strobiliformis* is rich and good. As it grows freely, and attains a considerable size, it is very suitable for that purpose, quantity being a great desideratum in ketchup-making.

**Marmalade.**—It is well known that the Seville Orange has been for years in high esteem, and formerly the price was much higher than for sweet Oranges; but there was no reason why that especial kind should not be grown elsewhere as well as in Seville: its growth has, therefore, now spread through the whole of the Orange-producing districts of Spain, as well as in the islands of Sicily and Malta, and the only difference between those grown in Seville and elsewhere is in the mode of packing. But this widespread growth has reversed the order of things with regard to price, for whereas the bitter Orange used formerly to be the dearest, it is now often the cheapest; and manufacturers of marmalade have taken advantage of the cheaper material which the increase of supply and the successive reduction of the sugar duties have put in their way, to supply the public with marmalade at prices which, compared with

twenty-five years ago, are about one-half. The quality of the article now supplied has also improved in about the same proportion as the price has diminished. Machinery has here, as elsewhere, of late been largely employed, and with present aids ten persons can produce as much marmalade in one day as formerly employed one hundred; and the public, not slow to appreciate really good and wholesome articles, consume at the present time twenty times as much as was consumed twenty years ago. A parcel of Malaga Seville Oranges was sold the other day at 1s. per half-chest, each containing 500 good sized Oranges; and even this price will leave a profit to the importer. Indeed, the fruit is so cheap in the producing districts that the freight to this country is more than half the first cost. The old notion of marmalade being adulterated with Turnips, Carrots, &c., I believe to be a mistake, for if such were used the article would not be even eatable.—*E. Pink.*

**Baked Apples.**—Apples of uniform size are selected, and simply wiped and cored. This last operation is quickly performed by punching them through the middle with an Apple-corer, thus removing the stem, seeds, and tougher parts, and making an opening for the introduction of sugar in the cooking operation which follows. After dipping the Apples in water, they are placed in any deep pan or baking dish, and sprinkled with sugar, about a teaspoonful to each Apple, and a tea-cupful of water turned on around them. They are then baked with a slow, steady fire till soft, when they should be removed from the baking pans for cooling and the table. When served with cream, this is a dish fit for the gods. Every part of the Apple can be eaten, the sugar having neutralised the acidity in the fruit, and the cooking making tender the skin. It is a capital substitute for Strawberries. There is another way of treating sweet Apples, which some of the ancients did not practise. Stew them in a porcelain kettle, with just enough molasses and water to prevent their burning, till cooked through, and then transfer them to the oven, with all the liquid residuum, to dry and brown. This gives a baked Apple, half jellied, delicious in flavour and moisture, that any one can enjoy.—*American Paper.*

**Absinthe.**—Absinthe is not rare in west-end clubs; a few words on its history, composition, and effects may therefore point a moral in Pall Mall as well as on the Boulevards. Few know how the insidious poison was introduced into Europe. *Artemisia absinthium* is the plant from which "green ruin" is extracted. It grows spontaneously in great abundance in arid and uncultivated regions, and its cultivation for the apothecaries and distillers has become a special industry during the last forty years. The best liqueur is manufactured in the little town of Couvet, in Switzerland, and at Pontarlier, in France. The proportion of alcohol in this liqueur is considerable, its flavour is strong, very aromatic, but not at all bitter. Workmen drink absinthe verte, or absinthe blanche, liqueurs of inferior quality, much less alcoholic, and much less mischievous. Absinthe is adulterated with Angelica, Spinach leaves, Nettles, and sulphate of copper occasionally. It has only been in use as a liqueur for the last thirty years. The extract of absinthe, a common apothecary's drug, was extensively used in Africa against dysentery in the camps. The bibulous ne'er-do-wells of the African legions acquired a liking for the medicine, and an officer of Marshal Bugeaud's staff introduced it as a liqueur into Parisian cafes, making, it is said, a great fortune by the innovation.

**Icehouses.**—Would you kindly give me some information as to the construction of an icehouse. I had one made which held nearly 300 loads. We filled it in November, 1871, and used about two cart-loads of the ice in April. It has only been opened twice since, until the middle of October, when it was found to contain only about three cart-loads. Such ought not to be the case if the house was well constructed; at least I think not, for we could keep the ice better when we had it in a stack. The sides of the house are built of brick, laid in cement, with a hollow cavity behind. The floor is laid with stable tiles, and the house is double thatched, first with straw, and then with heather. There is a good passage and double doors; but no ventilation. Would two or three air tubes assist in keeping the ice longer?—THOMAS ASHB, *Armagh*. [The sides and roof of the house seem properly formed to protect the interior from atmospheric influences. Has the mistake of putting open-air drains below the flooring been made? If so, take the drains up, fill with sand and relay them. The most probable cause of the ice not keeping well was in the fact of its being thin and watery when stored. Ice stored from the comparatively slight frosts of the winter in question did not keep well. Too much stress cannot be laid on the recommendation to pound and pulverise the ice when stored; strong mallets and strong arms should be freely applied for the purpose. Ventilation in an ice well is a matter of difficulty in arrangement, and of doubtful efficiency. The more completely the well is kept from the fluctuations of the outer air the better.—W. F.]

## WORK FOR THE WEEK.

## PRIVATE GARDENS.

**The Flower Garden.**—When the weather is dry, add some turfy loam and well-decomposed manure to beds where large plants, such as those of *Ricinus*, *Ferdinanda*, *Wigandia*, and other gross feeders, are to be grown, *i. e.*, if the beds are now empty. If the soil last year was found to be too moist, turn it out, and place a layer of stones, broken bricks, &c., in the bottoms of the beds. Mulch all newly-planted shrubs or trees, and affix strong but neat stakes to such as require support. Prune back pretty hard some Clematises for early flowering; some of the hardier Rose plants may also be pruned for the same purpose. Tree Pæonies, Myrtles, the Japanese Quince, and several other rather tender plants, should have a little protection from frost; for although their roots and principal stems might escape unharmed, their young shoots might be considerably injured. Lay Box and other edgings, and prune and tie up climbing plants. Where new lawns are intended to be made, the ground should now be cleared of all superfluous trees and shrubs, and the soil should be trenched over, turning all rough material into the bottom of the trenches, and making the whole perfectly level, smooth, and firm by means of rolling and raking. The seed should be sown in the latter half of this month.

**Bedding Plants.**—Hot-beds should now be put up for the propagation of these where hot-water heated structures are not available for that purpose. Such beds may either be raised above the ground or sunk, and in extensive places some of both kinds will be found serviceable. A little extra warmth may be communicated to ordinary frames by means of a lining of fermenting material applied to their sides; this additional heat will induce the plants to start into growth and to soon begin to yield material for cuttings. Propagation of *Verbenas*, *Heliotropes*, *Ageratums*, and other soft-wooded plants should now be commenced, and places heated slightly should be prepared for the reception of the young plants when they are rooted and boxed or potted off. Apply a brisk heat to *Solanums*, *Ferdinandas*, *Abutilons*, *Wigandias*, and other strong-growing sub-tropical plants that were starved in pots last summer, for producing stock, and pinch out their tops, so as to induce the formation of side shoots for propagating purposes. Seeds of various kinds of plants for summer gardening may now be sown, such as those of *Acacia lophantha*, *Cineraria acanthifolia* and *maritima*, *Acanthus latifolius*, *Centarea*, *Cannas*, *Pyrethrums*, *Lobelias*, &c. *Perillas*, *Marigolds*, *Stocks*, *Asters*, and similar plants are best left undisturbed until next month.

**Specimen and Exhibition Plants.**—Large *Heaths*, *Chorozemas*, *Boronias*, *Dracophyllums*, *Genetyllises*, *Aphelandras*, and similar plants should now be staked and tied into such shapes as it may be desired they should assume. A position near the glass is best, and especially one in which all sides of the plants may be subjected to an equal degree of light. In training plants of *Dracophyllum*, unless the long shoots are twined round the base of the plant, and only the points of last year's shoots allowed to grow upwards, a symmetrical or handsomely grown specimen cannot be obtained. Many train the old wood of these plants over a trellis and allow the blooming points to project outwards a little, but the result of such a method is not satisfactory. From specimen *Heaths* whose roots were reduced last summer when repotted, no flowers can be expected during the ensuing summer, and any blossoms that do appear should be removed so as to promote free growth. *Heaths* whose roots are so reduced generally take two years to recover their former vigour, but the second year after the operation, if they have been judiciously treated, a magnificent amount of bloom may be expected. Show and fancy *Pelargoniums* keep in a cool well aired house and in close proximity to the glass. If the stages do not permit of them being near enough to the glass, raise them upon inverted pots, blocks of wood, bricks, &c. Although wirework for training purposes was refixed when the plants were cut back, no attempt should be made to tie down any of the shoots yet; on the contrary, a slow and stocky growth should be encouraged, which is the most productive of flowers; no fire-heat should therefore be employed for these plants in winter beyond what is necessary to expel frost. If required for early shows a little fire-heat maybe applied after February. *Allamandas* may be repotted, cut well back, and allowed to break freely; they should be kept moderately dry for a time. *Dipladenias* will now be producing their young wood, which should be trained to fine string run across the rafters inside the stove. If the pots in which they grow are plunged, or even partially so, in a moderate bottom heat, it greatly assists their growth; and if the wood is produced early without check, and by free exposure to light made firm, abundance of flowers will doubtless be the result. If not already done bring down the shoots of *Clerodendron Balfourii* and *splendens* and train them around the trellises

fixed on the pots. As *Clerodendrons* produce their flowers from the old wood none of it should be removed at present; but after they have done blooming they may be pruned, repotted, and encouraged by bottom heat and a high temperature to produce their young growths, which should be trained along the inside of the glass on threads, as recommended for *Dipladenias*, with the exception of the difference of season, *viz.*, *Dipladenias* from the middle of January until they begin to come into bloom, and *Clerodendrons* from the time they have done blooming until they form and thoroughly mature their young shoots, which will be the blooming ones of next season. *Stephanotises* may now be unfastened from the cords on which they have been supported and trained around their trellises; if required early, raise the temperature of the house or transfer the specimens to a warm moist stove. A too high temperature in winter is, however, more injurious than beneficial, as it deprives them of their proper rest; but it must not be allowed to fall under 55°.

**Indoor Fruit and Forcing Department.**—For *Pines* prepare a good stock of soil for potting, and lay it under cover for some time prior to using it. Water the plants but sparingly, avoiding too much drought, or, on the other hand, a soddened condition of the soil. For stock plants maintain a night temperature of 70° and a bottom heat of 80°; 10° lower temperature will be quite enough for succession plants, which should not be excited till the end of the month. No *Vines* should be allowed to carry any of last year's fruit till now, and if any bunches are still hanging on them, they should be cut off at once, with pieces of the wood attached to them, inserted in bottles of water, and kept in the fruit room; this allows the *Vines* to be properly pruned, and to be got in readiness for starting into growth at any time when required. Give some manure-water to pot *Vines* that are swelling fruit, and keep them in a brisk, moist temperature; 65°, with a dry atmosphere and a little air, are necessary for such as are in bloom. Syringe daily *Peaches* and *Nectarines* that have set their fruit, and attend to disbudding and watering whether the plants are in pots or borders. Keep *Figs* in pots in a bottom heat of from 75° to 80°; if maintained by means of fermenting material so much the better. Syringe daily, and supply water moderately. Keep those for late work in sheds or turned on their sides under stages, quite dry. Prepare hotbeds for *Cucumbers*, placing a little mound of good soil in the middle of the bed over the manure, and letting it rise to within 6 inches of the glass; one mound under each light is sufficient; shift seedling *Cucumbers* into larger pots, and a day or two afterwards pinch out the top of the leading shoot. Maintain a night temperature of 70° both in pits and frames, both for *Cucumbers* and newly-planted-out *Melons*. Keep up a succession of *Strawberry* plants; early *Peach*-houses or *Vineries* will be good positions for the earliest batch; succession fruit houses for the next earliest crop, and frames for a late supply. *Mushroom* beds, if at a temperature of 60°, may now be spawned. Continue the forcing of *Asparagus*, *Seakale*, and *salading*. Sow some seeds of vegetables for very early crops on slight hot-beds.

**Hardy Fruit and Kitchen Garden.**—The pruning of fruit trees, and also the nailing of such as are grown against walls, should be proceeded with, more particularly those grown on south walls. Whilst the mornings continue frosty, manure may be wheeled on to open quarters, the remains of spent crops, such as *Cabbage* or *Brussels Sprouts*, should be cleared off, and preparations made for other crops. Plant some early *Potatoes* in a warm position on a dry light soil. Make new plantations of *Strawberries*, if such was not done in autumn. Make new plantations of *Horse-radish*, *Jerusalem Artichokes*, *Rhubarb*, &c. Sow some early *Cabbage* seeds, also a pinch of *Savoy* seed in a warm situation for early crops. Of *Garlic*, *Shallots*, and *Rocamboule* plant some bulbs in rows a foot apart, and 6 inches asunder in the row. *Tansy*, *Tarragon*, and some other herbs should have their crowns divided, and fresh plantations made, if necessary, with the divisions.

## NURSERIES.

**Indoor Department.**—Proceed with the grafting of *Correas*, *Boronias*, *Azaleas*, *Camellias*, &c., and keep the frames in which they are set closely shaded with pieces of newspaper. Proceed with the propagation of soft-wooded bedding plants, such as *Tropæolums* of the *Lobbianum* section, *Petunias*, *Verbenas*, *Lobelias*, *Salvias*, *Heliotropes*, *Ageratums*, *Pelargoniums*, *Fuchsias*, *Lantanas*, &c. If old plants of these are now placed in a brisk heat, abundance of cuttings may be obtained, and very soon after the cuttings have become rooted, they, in their turn, will afford young tops for the same purpose, so that before May, with plenty of room, heat, moisture, and some old plants to begin with, a good supply may be obtained. The finer kinds of autumn-struck *Pelargoniums* may now be potted off singly into large sixty or forty-eight sized pots, and replaced in their old quarters; if the house, frame, or pit containing them be kept

rather close for some days after the introduction of the newly potted plants, scarcely any check will be sustained. Keep Heath cuttings in frames tolerably close, in a temperature of 45°; shade with canvas or newspapers from midday sun. Pot old stocks of Hollyhocks in good rich soil, and place them in an intermediate house, so that the shoots may be taken off as they grow, and be used as cuttings. If the roots were potted in October or November, and since then wintered in a frame, they will start much more freely than newly potted ones. Prick off young Cyclamens into pots or pans, and keep them near the glass in an intermediate house or pit. Cyclamens are commonly sown in early spring, but, treated in that way, good flowering plants by next winter are seldom obtained, whereas those sown in November in a temperature of 45°, pricked off when they have made two leaves into pots or pans, form excellent blooming plants by the time they are 12 or 14 months old. Plants of *Euphorbia jacquiniiflora* that have done flowering, should have their flower tops pinched off. They should then be encouraged, by means of additional heat and moisture, to make fresh shoots, which, taken off with a heel, or even without one, and inserted under a handglass like ordinary stove plant cuttings, strike as freely as *Verbenas*. The stems of these plants are commonly cut up into little pieces, each having one or two eyes, which are treated like *Poinsettias*, *Vines*, &c., but they do not form such nice plants as those obtained by the former method; neither do they root so quickly nor grow so fast as cuttings do, and the earlier the latter are rooted and the stronger they become before their flowering period, the finer will their inflorescence be. Vine eyes should now be inserted in 60-sized pots, which should be plunged in a moderate bottom heat. If shoots have been saved from *Vines* pruned more than two months ago, and their ends inserted in a border since that time, they will afford good eyes from which to propagate now. *Roses* grafted in November and December, if they have taken well, should be repotted into large 60-sized pots in a good loamy soil. Pot singly rooted cuttings of *Ixoras*, *Dracenas*, *Aphelandras*, *Eranthemums*, *Hoyas*, *Gardenias*, &c., as they become ready, and keep them in a moist brisk temperature. Make a little incision around the stems of *Dracenas*, *Dieffenbachias*, tall-stemmed *Alocasias*, &c., just below the crowning tuft of leaves at the summit of the naked stem, and tie around the incision some damp moss mixed with silver sand, so as to induce the plants to callus and emit roots before they are separated from the parent stock.

**Frame Ground, &c.**—Heaths and other greenhouse plants in frames should be well ventilated on every favourable opportunity, but protected from frost when it occurs by having mats spread over the glass. The sides of the frames should be protected by means of a lining of straw. *Ivies*, *Rhododendrons*, *Jasmines*, *Clematisses*, *Skimmias*, *Magnolias*, and other plants in pots, but not in frames, should be protected from frost by means of a framework of hoops covered over with mats. Every thing at all tender out of doors in pots should be plunged in coal ashes, cocoa-nut fibre, or other material, even although unprotected in other respects. Any somewhat tender small *Conifers* or other evergreen or deciduous plants grown out of doors and likely to be injured by frost should have some straw strewed over them at night, and if the frost abates in the morning it should be removed and again applied at night. Proceed with digging, trenching, transplanting, pruning, and other seasonable operations.

#### MARKET GARDENS.

Get stumps of *Brussels Sprouts* and *Savoys* cleared off old plantations of these vegetables as speedily as possible, and cart manure on to the ground, which should be dug two spades deep, or else trenched and ridged. A few of the finest of each kind should be saved for seed, and should be transferred for that purpose from the open ground to the sides of hedges or to other odd corners. Lift any *Parsnip* roots still in the earth with forks, so that the ground may be prepared for other crops. Keep the hoe at work amongst young *Cabbages*, so that a strong and vigorous growth may be encouraged. Expose freely, throughout the day, *Cauliflower* plants both in frames and under hand-lights, and at night, when the sashes are put over them, tilt them up a little, both at back and front, so as not to crush the leaves, and also to keep the plants pretty hardy. Although subjected to a few degrees of frost, they will not suffer if they have been previously properly cultivated. *Lettuces* in frames should be quite as freely exposed to the air as *Cauliflowers*, but great care must be taken to guard against cold rains, hail, or snow, for such would produce damp amongst them; therefore replace the sashes immediately such unfavourable circumstances present themselves. Thin such beds as are too thick, and dredge well with dry sand or wood ashes. Lift *Rhubarb* roots as required; indeed all that are intended to be forced should now be lifted, and built up into beds, which may be started into growth in succession. Keep up a brisk temperature in such beds as are being forced, and recruit declining heat by means of fresh linings. Of *Asparagus* and *Seakale* also keep

up a good succession. Take great care of *Radish* beds; uncover them every morning when the weather is at all favourable, and replace the litter at night. Preparations must now be made for *Potato* planting, and a piece of the driest ground should be selected for the earliest crop; between fruit bushes, if not too close, will do for the later ones. *Wallflowers* are now coming freely into blossom; and *Sweet Peas* are also growing apace; stakes should, therefore, be applied at once to the latter, if not previously done. Sow some seeds of *Stocks* in a frame, moderately heated, for yielding flowers in early summer.

#### MESSRS. SUTTONS' NEW SEED WAREHOUSES.

THE *Builder* of last week has a good illustration of the Market-place front of Messrs. Suttons' handsome new seed warehouses at Reading. During the last few years (says our contemporary) nearly the whole of the extensive premises belonging to this well-known firm have been either remodelled or rebuilt. The frontage to the market-place remained, however, until quite recently, as heretofore; but possession having been obtained of two houses immediately adjoining, the present handsome structure has been raised. In the front, which is built of white Mansfield stone, are three noble arches, two of which are windows lighting the retail departments; whilst the third, somewhat more elaborate in design than the others, forms, in connection with corridors, the main entrance to the whole of the establishment. The first floor is devoted entirely to the purposes of a library and recreation-room, and has lavatories attached to it. The ground-floor is 15 feet high; the first floor 14 feet, and the total height from the pavement line to the flat of the roof is 63 feet. Immediately at the rear of the market-place block of buildings, is the sample market, 78 feet long, where single sacks, as specimens, of nearly all the more bulky garden and farm seeds, stacked in the larger stores, are ranged for inspection. One of the most remarkable of the departments, however, is that devoted to the execution of kitchen garden seed orders. Here is a room, 92 feet in length, connected with five smaller rooms, all of which are lighted entirely from the roof. The wall-spaces thus obtained are fitted from floor to ceiling with numberless drawers and shelves, loaded with many thousands of packets of seeds, of various dimensions, ready for sending away. Farther on to the south, the buildings are occupied by farm-seeds in sacks, piled in regular order one above another, an avenue being left down the centre. The dimensions of this portion are:—Length, 161 feet; breadth, 34 feet. The whole is terminated by a handsome and capacious lecture hall, completely fitted, with open-timbered roof, stained and varnished and plastered between the rafters. On the opposite side of the road, Messrs. Sutton have built and fitted up a coffee and refreshment house, which is largely used, not only by their own men, but by many others who prefer getting their meals there to the plan of resorting to an ordinary public house. The total cost of the new buildings, exclusive of land and fittings, has been about £17,000.

#### LAW NOTES.

**Lopping Overhanging Boughs.**—Employers are liable for the acts of their servants, but how far landowners are liable for the acts of their trees seems open to doubt. At Newport, a few days ago, Mr. Inglis Jones was summoned for neglecting to cut some trees of his which overhung the turnpike road, after having received a notice to do so. The trees extended over half the road, and it was alleged they obstructed the air and sunlight, that droppings from the boughs damaged the road, and that the lowness of the branches to a certain extent impeded the traffic. On the other hand, evidence was produced to the effect that the trees were ornamental, that they formed part of a plantation, and that the lowest bough was 24 feet 3 inches high. In the end no order was made on the subject, and it is to be presumed that the trees will escape amputation. In the meantime there can be no doubt that when trees standing near a highway are about to be lopped or cut down, due notice should be given to passers-by. On Tuesday an inquest was held at St. George's Hospital on the body of a man, aged sixty-four years, who expired from injuries received by the falling of a tree standing in the grounds of Stratheden House, Knightsbridge. The unfortunate man was walking along the pavement, when he was struck to the ground by the descent of the tree, which was about to be cut down, but suddenly fell without warning, the roots at the back part of it having some time before been cut to make way for the footing of a wall. A verdict of accidental death was returned, and it would be as well in future that when trees standing near a highway so frequented as Knightsbridge are in an unsafe condition, notice should be given to foot passengers of the danger they incur by walking past the premises.

## THE GARDEN.

—o—o—o—  
 "This is an art  
 Which does mend nature: change it rather: but  
 THE ART ITSELF IS NATURE."—*Shakespeare.*  
 —o—o—o—

### BOUQUET MAKING.

THE present season of the year gives better opportunity perhaps than any other for thoughtful practice in one of the most beautiful and interesting of the fine arts—the arrangement of a few cut flowers into a bouquet deserving the name. A well made bouquet is the little lyric poem, so to speak, of the thorough gardener. The greater and more lasting efforts of his talent, those set forth in the arrangement of his outdoor shrubs and plants, should deserve the name of his epic or his dramas: the fragrant little bunch of blossoms he calls his bouquet, culled with judgment, and arranged with due regard to the laws of harmony and common sense, should quite as well deserve to be looked upon as a sort of ode or sonnet, representing in miniature the ideas of the garden itself, though requiring a treatment of its own. Summer always provides for every one; it is difficult for a man to go astray in arranging cut flowers, when the full tide of June and July comes to wrap him round; Nature then almost speaks for herself as to what shall be done. The general rules and principles are nevertheless the same; and however wealthy the bouquet maker may be in material, and however easily things may in summer time seem to fall into their proper places, he should still go on educating his taste. Would that the world in general could or would learn the difference between a bouquet and a mere handful of flowers! However pretty individually, however sweet and shapely each one may be in itself, if taken at random, and simply tied together, flowers they are still, it is true—we cannot cancel the beauty of that little fact—but they are no more a bouquet than the run of the fingers, vaguely and wantonly, over the strings of a harp, is productive of music. There must be symmetry of general form, not mathematical symmetry, but such as we see in a Birch or a Chestnut,—for a bouquet may in general design be either light and tender, or massive and sumptuous; there must be accurate balance also of colour, with plenty of white and green, and a nice concord of scents. The last-named particular, though often one of the least regarded, or never thought of at all, is in reality one of the most vital. The very name "bouquet" carries with it, indeed, this identical idea, being derived from certain ancient words which imply "perfection of odour." The dictionaries often assign it to the French term for a bush, but, excepting in connection with the arbitrary and exceptional term a "rose-bush," the latter hit of etymology may be let go whither it pleases. Sound the word, without thinking of the modern way of spelling, and we are at once reminded of its kindred term, *tokay*, literally the wine of royal odour. These three essentials, general figure and arrangement, proper blending and counterpoise of colours, and a scientific adjustment of the qualities called perfume, stand accordingly side by side in regard to the *beau idéal* of our undertaking. A trifle judiciously thrown in, of some odour comparable with deep bass, or even with a good treble, will often as completely change the quality of a bouquet as a bit of scarlet where previously there was no accent. This matter of the adjustment of odours is so important, not only in bouquet-making, but in reference to conservatories, where the glass often shuts in things that simply slaughter one another, that we shall probably return to it at some future time. Meanwhile we simply name it, as a point never to be lost sight of by those who would be artistic in their every-day life, and who would prove and understand what is incontestably true, though not perhaps seen on the instant, namely, that the "common things" of the world are exactly those which can be devoted the most satisfactorily to the production of the purely beautiful. Colours require to be disposed, as to tone and contrast, after precisely the same principle as that which guides a lady of sense in the choice of apparel. One who is a curiosity in respect of dress must never be expected to produce a good bouquet, let her try till her

fingers ache; and contrarywise, if we want a gem in the way of bouquet-making, we may look with hope—well, certainly *not* to one dressed according to the "newest fashions" and within an inch of her life. All colours are good somewhere and at some time, though the best of the brilliant class may be utterly lost as to effect by mal-arrangement; while delicate ones may be made seem wan and worthless just for want of a little study of what constitutes a wise and friendly juxtaposition. Fancy, for instance, in the flowers of to-day, the effect of the sweet and tender yellow of the winter Jasmine alongside of a white; and, as a contrast, mark the effect of a bit of Maiden-hair Fern placed somewhat *en rapport* with a white Camellia, or of the timely introduction, amid pearly things, of a spray of the scarlet Euphorbia *jacquiniæflora*. There are flowers that should *never* be used in bouquets. These, however, we may speak of another time; for although it must be a remarkable plant indeed for which a suitable place could not be found in the open garden, it is quite a different thing when we have to bring the garden rays, as it were, to a point. There is not a plant in existence that is unfitted to give a charm or a tinge of splendour to scenes receptive of it; and in a certain sense, there is scarcely a plant that may not be utilized as a decorative object. But the bouquet has limitations. In dealing with plants and flowers we are bound not only to treat them kindly, but to treat them justly and honestly, and as members of a community entitled to its rights as well as ourselves. They will be sure to repay our care and equity. The goodness of even the simplest nosegay is dependent exactly upon the amount of thought put into it, and of desire on the part of the artist to be as fair and faithful to the gifts of Flora as we are bound to be to all other things.

### ROYAL HORTICULTURAL SOCIETY'S ANNIVERSARY.

THE annual meeting of the Royal Horticultural Society is announced to be held on Tuesday next at 3 p.m. The retiring members of the Council are the Bishop of Winchester, James Bateman, Esq., and G. F. Wilson, Esq. The names of Fellows recommended by the Council to fill their places are Lord Alfred Spencer Churchill, Major R. Trevor Clarke, and Lord Londesborough. The following are recommended by the Council to fill the several offices in the ensuing year:—President: His Grace the Duke of Buccleuch, K.G. Treasurer: Mr. John Clutton. Secretary: Major-General H. Y. D. Scott, C.B. Expenses committee-men: Mr. John Clutton, Mr. John Kolk, Mr. W. Wilson Saunders, F.R.S. Auditors: Mr. James Nicholson, Mr. John Gibson, and Mr. Robert Hudson, F.R.S.

Respecting the election of Fellows to fill the vacancies in the Council caused by the retiring members, we have received the following from the Rev. C. P. Peach:—"Allow me to state in your columns that the Rev. S. R. Hole and Mr. B. S. Williams will be proposed, together with Major R. Trevor Clarke (one of the nominees of the Council), to fill the places of the members of the Council who are vacating in rotation. I need not, after the recent notice of the Rev. S. R. Hole in your paper, add anything to show how fit a person Mr. Hole is to fill a space at the board, both mentally and physically. Mr. B. S. Williams is to represent the interests of the nurserymen, who, as a class, have done more than any others to promote the true interests of horticulture. I feel sure, therefore, that most of your readers will agree that we cannot appoint two better men to represent the practical interests of horticulture. I do not wish to say anything against Lord A. Spencer Churchill and Lord Londesborough, but I do not think we want persons merely to lend their names and to give an air of nobility to the Board. What guarantee have we got that they will ever attend? Hitherto, the Council of the R. H. Society have been more conspicuous at the provincial meetings by their absence than by their presence, and I have heard many deep and just complaints that the interests of the working bees of horticulture are disregarded. If those Fellows of the R. H. Society who are not able to be present will take the trouble to fill up their voting papers with the names of the Rev. S. R. Hole and Mr. B. S. Williams, and will send them to the Assistant Secretary of the Society previous to Tuesday, 11th inst., they will help to secure that practical horticulture be for once admitted to have a voice on our Council, and will break down the present rule whereby the Council themselves dictate to the Fellows who are to be their associates on the Council Board."

Since writing the above I have received a copy of the bye-laws, in which it is stated (110) "That if any Fellow desire to substitute the name of any other Fellow for that of any one recommended by the Council for removal or election in the said balloting lists, such

Fellow, within seven days after the said lists have been circulated, shall leave at the office of the Society notice in writing of every such proposed substitution." This does not seem to me to accord with Rule 81, and in the balloting list sent round, the foot-note, which purports to be a copy of the Form F., omits the important words, "The name of the Fellow mentioned in any notice given in pursuance of the byelaws for whom he chooses to vote," and the words are, "Any Fellow who disapproves of the names recommended above is requested to strike out such name as he does not approve, and to write opposite to each one so struck out the name of the person for whom he chooses to give his vote." This does not lead any Fellow who receives this balloting list to conclude he can only put in the name of one proposed according to Byelaw 110, and still more it does not allude to Byelaw 114, which is more stringent still. I maintain, therefore, that any Fellow who receives the majority of votes according to the balloting lists sent round, and which, if the instructions on the list are to be followed, may be returned with the names of any Fellow proposed by the Council erased, and another substituted in its place—I maintain, I say, that such Fellow will be properly elected.

### NOTES OF THE WEEK.

— THE hardy spring-flowering *Cyclamens* (coam, vernum, Atkinsi, &c.) are now in brilliant bloom in Mr. G. F. Wilson's garden at Weybridge Heath, and have been so for the past three weeks. Such hardy gems should be cultivated much more extensively than they are at present.

— WE understand that the successful candidate for the clerkship at Kew is Mr. George Nicholson, Sharow Cross Nursery, Ripon, Yorkshire.

— OF *Dendrobium Hillii* there is at present a magnificently flowered plant in the cool Orchid-house at Kew. The specimen in question though by no means handsome as regards growth, has on it as many as 20 flower-spikes, each averaging as many inches in length, measuring from the lowermost buds to the end of the spikes, which are densely covered with flowers, two spikes in several instances emanating from one bulb. *D. Hillii* is an Australian species somewhat in the way of *D. speciosum*, but not quite so compact either in habit or inflorescence.

— A MEMORIAL was lately presented to Mr. Gladstone, signed by a number of eminent botanists, against the removal of the botanical collections at Kew to South Kensington. The reply, addressed to the Rev. M. J. Berkeley, says:—"Her Majesty's Government have not formed the intention of removing the collections to South Kensington, and should anything lead them hereafter to entertain the idea, they will take care that ample notice shall be given, and that the judgment of the persons most accomplished in botany shall be fairly weighed in the first instance."

— WE have just received from Mr. Rivers, of Sawbridgeworth, a boxful of ripe Oranges, large and beautiful in appearance, and exquisite in flavour, each fruit having attached to it a cluster of the bright green leaves of the tree on which it grew. They consisted of the Prata or Silver Orange, the Maltese Blood, the White Orange, and the Egg Orange, all fine specimens of their respective kinds. With here and there an exception, home-grown Oranges are scarcely worth eating; but the specimens before us clearly show that with the command of an orchard house, and a little heat, to keep out frost, and to help them at the commencement of the growing season, anyone can grow Oranges much better than any that are imported. Their fresh green foliage, too, and delightful odour render their appearance on the dessert table very welcome. A friend to whom we submitted some of these specimens pronounced them to be the best Oranges he had ever eaten.

— A FEW winters ago (says the *Grocer*) we were consulted by a friend who had a small greenhouse containing half-hardy plants that only required a little protection during hard frost. Gas had been tried and was found to be ruinous to his plants; we therefore suggested that he should buy a dozen common cheap paraffin lamps, light them, and distribute them in different parts of his greenhouse. The experiment was tried, and found satisfactory. The present frost suggests that the same expedient might be used with equal success by others. Suitable lamps may be bought from 6d. each and upwards. In selecting them, they should be chosen with a large vase in proportion to the size of the flat wick, in order that they may continue burning all night without refilling or other attention. A large number of such small lamps has an advantage over a single large one, as by judicious arrangement their heat may be equally distributed throughout the greenhouse. It will be readily understood that whether one or many lamps are used, the total amount of heat

given off is proportionate to the quantity of oil burned, provided the combustion is complete; and in using a lamp all the heat of combustion is utilised—none goes up the flue, as with stoves and fireplaces.

— WE learn from the *Athenæum* that when, in April next, Mr. Henry Cole retires from the post he has so long held at South Kensington, General Scott will succeed him as secretary. Mr. Cole will undertake the management of the London International Exhibitions.

— WE are informed that the following are the arrangements of the Manchester Botanical and Horticultural Society for the present year:—Floral and horticultural meetings at the Town Hall, Manchester, on Tuesday, February 11th; Tuesday, March 25th; and Tuesday, October 21. The annual Whitsuntide show, May 30th to June 6th; exhibition of American plants by Mr. Anthony Waterer, to open on May 30th; international exhibition of fruits, vegetables, and autumnal flowers, September 3rd, 4th, 5th, and 6th.

— IT was agreed at a recent meeting of the Scottish Arboricultural Society that the following deputation be appointed to visit the forests of Germany and France:—Mr. McCorquodale, forester, Scene Palace; Mr. Thomson, deputy surveyor, H. M. Chopwell Woods; Mr. T. Methven, nurseryman and seedsman, Edinburgh; Mr. D. Syme, Edinburgh; and Mr. Anderson, jun., Perth. That the treasurer receive subscriptions from members of the Society, to assist in defraying the expenses of two of the deputation, the others to pay their own expenses. Dr. Cleghorn stated that he would draw out a plan of route for the deputation, and give them all the information he could for their guidance.

— IN the Report of the Council of the Manchester Botanical and Horticultural Society to the 45th annual meeting, held the other day, we learn that, notwithstanding an almost unprecedentedly wet and unfavourable season, the working of the past year has resulted in a gross profit of £555 18s. 2d., and in a reduction of the debt to the amount of £263 7s., a result mainly attributable to the successful Horticultural Exhibition held at Whitsuntide. We also learn that the total income of the Society for the last year was £4100; the total expenses of the great show at Whitsuntide £1213, and the receipts £2016, showing a profit of £800. This return was realised, notwithstanding that some 5000 or 6000 persons were admitted under cover of season tickets. At this Exhibition the sum of £652 was awarded in prizes, of which amount £86 was presented in special prizes.

— KEW BRIDGE is to be opened to the public to-day, and great preparations have been made to celebrate the event. Among other influential gentlemen invited to take part in the proceedings, besides the Bridges Joint Committee and their officers, are the Lord Mayor and the Sheriffs of London and Middlesex, the High Sheriff of Surrey, Viscount Enfield and Lord George Hamilton (members for Middlesex), Mr. H. W. Peek and Sir R. Baggallay (members for Mid-Surrey), Lord John Manners, M.P., the Chairman of the Local Magistrates in Middlesex and Surrey, the representative of the late owners of the bridge, &c. The civic guests will be met near the Gunnersbury Station about 2 o'clock, when a procession will be formed, headed by the band of the Honourable Artillery Company. On reaching the bridge, which will be tastefully decorated, the key of the gate will be delivered up, and the bridge declared free for ever. The procession will then cross the bridge, drive round Kew Green, and return to the Star and Garter Hotel, where luncheon will be provided for eighty guests, the chairman on the occasion being Mr. James Montgomery. The opening of this bridge will be a boon to the numerous visitors to the Royal Gardens.

— THE Tyneside Naturalists' Field Club propose (says *Nature*) to obtain a complete record of all remarkable trees at present growing in the district embraced by the club, whether from their age, dimensions, or historic associations. Seventy or eighty such trees have already been catalogued from information supplied by the members of the club; and it is proposed that the record shall be as full and complete as possible, both in respect to letterpress and illustrations. The letterpress is to consist of the fullest particulars obtainable as to measurements and history, and it is recommended by the committee appointed that the illustrations be photographs taken by some permanent process, either Swan's "carbou" or the "Woodbury;" the expenses to be paid out of the general funds of the club, the catalogue to be supplied to members of the club for a small subscription, to the general public at a higher rate. It is obvious that such an illustrated catalogue will become very useful in after years, especially if the observations are repeated on the same trees at intervals. Though the Woolhope Club has already published in its reports photographs of a few remarkable trees, we do not recollect that anything of this kind has been hitherto attempted in a systematic way.

THE INDOOR GARDEN.

VANDAS.

ORCHIDS generally are not remarkable for beauty, except when in flower; but some of the tropical Vandas, of which *V. suavis* and its congener *V. tricolor* may be taken as types, are, when well furnished with fresh green foliage, truly elegant in appearance. The grand specimens of Vandas at Chatsworth are amongst the most remarkable that I have seen, one plant alone of *V. suavis* having borne no fewer than twenty fine spikes, on which a large proportion of the flowers were open at one time. When well grown, Vandas may, indeed, be considered the noblest of all East Indian Orchids, not even excepting Phalaenopsis themselves, which is saying a great deal in their

*Vanda suavis.*

favour; but I refer more particularly to their graceful habit. Vandas require a warm atmosphere, rather close, and a plentiful supply of moisture both at the root and also in the atmosphere, more especially when growing; they should, indeed, never be allowed to become thoroughly dry at the root, not even when at rest. Vandas are apt to shrivel during dry, frosty weather, unless the atmosphere is kept moderately moist, and if once they become debilitated in an arid atmosphere, it requires a great deal of time and care to enable them to recover their former freshness; it, therefore, becomes necessary to keep up the moisture even during winter, while an occasional light syringing on bright sunny mornings is beneficial in preserving them in vigorous health. Dryness at the root at any season renders them liable to lose their lower leaves, and to become what is technically called "leggy"—a state of things to be avoided as much as possible. There are

about twenty species in cultivation, but the following selection comprises the best of them:—

*V. CATHEARTH.*—This reminds one of a remarkably robust growing *Renanthera*; it bears short, pendant spikes furnished with four or five waxy flowers, the sepals and petals of which are chocolate-brown, with yellowish transverse bars, the three-lobed lip having a peculiar thickened margin round its central lobe. This is yet a rare species in collections, though one of the fastest growers we have. It does best at the cool end of the East Indian house, and should be repeatedly syringed daily when in a growing state.

*V. CÆRULEA.*—This is remarkable on account of its blue flowers, a colour extremely rare amongst epiphytal Orchids. It is one of the finest species in cultivation, bearing spikes of nine, sixteen, or even more flowers, which vary in size from 3 to nearly 5 inches across. This species is found growing on trees, and its flowers in a wild state are of a more intense blue than those which are produced in our dull English climate. *V. cœrulea* grows at about the same elevation in Assam as *V. Cathcartii* does in the Sikkim Himalayas. It flowers during the winter months, a circumstance which makes it doubly valuable, and it lasts in flower fully a month.

*V. INSIGNIS.*—This is one of the finest species in cultivation, and one which must not be confounded with the variety of *V. tricolor*, long known and sold under this name. This plant is a native of Java and the Moluccas, and was figured by Blume in his "Rumphia" many years ago, though it has only recently been introduced to our gardens by Messrs. Veitch. It bears from three to seven flowers on a short spike. The sepals and petals are of a cinnamon-brown spotted with darker brown. The lip is three-lobed, the central lobe being concave and of a delicate lilac colour, white at the base. The true *V. insignis* is one of the rarest species in cultivation.

*V. SUAVIS.*—This fine old species bears pendant spikes of white flowers blotched with rich purple. There are several fine varieties of it in cultivation, of which the plant represented by the accompanying woodcut is one of the best.

*V. TERES.*—This is a distinct habited species, from the jungles of Burmah and Sylhet. Its terete foliage puts one in mind of *Rhipsalis funalis*, being of a bluish-green colour, and about as thick as a swan's quill. It bears erect spikes of large flowers of a delicate purple and white colour. The lip is streaked with crimson-purple, and suffused with yellow. This plant has been grown and exhibited in fine condition by Mr. Denning, gardener to Lord Londesborough, and when well flowered it may be considered to be one of the finest species in cultivation, though common in every collection. *V. teres* var. *Andersonii* is a better coloured form than the original species.

*V. TRICOLOR.*—This species and *V. suavis* resemble one, another in most respects excepting in colour, the flowers of tricolor having a yellow ground instead of white. There are several variable forms of this plant, two of the best of which are *Dodgesonii* and *Russelliana*, both named after enthusiastic amateur cultivators in the north.

The other kinds in cultivation are the following:—

- |                        |                          |
|------------------------|--------------------------|
| <i>V. Batemami.</i>    | <i>V. gigantea.</i>      |
| <i>V. Bensoniae.</i>   | <i>V. Hookeri</i> (rare) |
| <i>V. cœrulescens.</i> | <i>V. Roxburghii.</i>    |
| <i>V. cristata.</i>    | <i>V. cœrulea.</i>       |
| <i>V. Denisoniana.</i> | <i>V. Parishii.</i>      |
| <i>V. alpina.</i>      |                          |

F. W. B.

IMPORTING ORCHIDS.

HAVING been repeatedly questioned in reference to this important subject, perhaps a brief allusion to it here may not be out of place, more especially as it is generally acknowledged that there is much to do in this way ere even our great collections approach completeness. We are moderately rich in epiphytal species, but terrestrial Orchids are but poorly represented, even in our best public and private collections, and will no doubt continue to be so until private enterprise clears the way to their introduction to this country. There are many localities where an enterprising collector might do well. The vegetation of Central Africa is as yet comparatively unknown, though not unheard of, and even the plants of the southern or Cape district, including some of the finest

terrestrial Orchids that could be grown, are as yet unknown to cultivators. The Orchids of Upper and Lower Assam, not to mention those of other parts of the great continent of India, are in the main unknown to cultivators. Suddiyah in Upper Assam is a rich locality for new or rare plants, which grow profusely in the neighbouring mountains. It is difficult for any European to enter these mountain gorges, as the wild tribes object to this; they, however, allow natives to enter, and they will bring down both flowers and plants, or both, for a mere trifle. These tribes, the Misloneys and Nagahs, come down to Suddiyah and Debrooghan to trade during the winter season, and return during the warm season to their hills. An officer lately in the Bengal army has kindly supplied me with his experience of various parts of India, and mentions many lovely Lilies, Primulas, Rhododendrons, and Ferns which he has met with in profusion whilst hunting and shooting in the mountains, but which he has never seen in cultivation. A collector going out to India should understand something of the language, or else make up his mind to take into his employ a native who understands some English, or innumerable difficulties will be thrown in his way. Many persons in this country have resident correspondents in India, who could in some favourable instances send over a case or two of choice Orchids. Plants that are known to grow in any special locality may be obtained by giving the native tribes graphic coloured drawings of them, and offering a certain small sum to the first who succeeds in bringing them from the hills. In addition to the plants mentioned above, different species of Iris, Myosotis, Delphinium, and Fritillarias were noticed in the vicinity of Panchoa. Panchoa is a small village near to the Oontadoora Pass, at an elevation of nearly 17,500 feet. The Orchids do not reach that elevation, but many herbaceous plants scarcely less beautiful or interesting might be obtained from that locality. Many parts of the Himalayan range might be thoroughly well investigated, with both pleasure and profit, by any well-qualified collector.

Collecting plants, however, is but half the duty of a collector, for if great care is not taken in packing and transporting them, there is every probability of their being lost on their journey to this country. If possible Orchids and bulbs should be packed when at rest, or during the dry season. Packed tightly in a common packing case, among dry fibre or shavings, at that season they generally reach this country in good condition. If the plants are growing, it becomes necessary to pack them more carefully in a glass-roofed plant-case, allowing the growths plenty of room. It is of but little use to crowd growing plants together in a case, for if one commences to decay the evil soon spreads, and a mass of stagnant rotteness is the result. A few robust plants carefully packed have a much greater chance of reaching this country in excellent condition than great numbers closely huddled together. In the case of some epiphytal Orchids, it is possible to obtain them thoroughly well established by lopping off the branches of the trees on which they grow. The logs so obtained can afterwards be trimmed, and if nailed or screwed firmly to the sides of the cases in which they are to be sent home, there need be but little fear of their reaching their destination in safety. *Phalanopsis Parishii* and *P. grandiflora* packed in this manner have often arrived in excellent condition.

In sending Orchids to this country from abroad, care should be taken to ship them so that they will reach here during warm weather. Inattention to this has disappointed many, when the only cause for failure was their having been shipped off too late in the season, and their having reached this country during the winter months. The rigour of our northern winters has ruined the contents of scores of cases of valuable plants, often after a large amount of both capital and labour had been expended to collect them in their native habitats. In the case of glass-roofed cases, it is a good plan to make arrangements, if possible, with the captain or other officer of the steamer on which they are placed, to have them shaded during bright sunshine. These little details will soon suggest themselves to the collector, but it is as well to know and prepare for any adverse circumstances that may render the importation of living Orchids less certain than it is at present. Many bulbs, and the tubers of many terrestrial Orchids, are best brought or sent over when at rest, packed in

their native earth. Many seeds of Palms and other tropical plants and shrubs are best sent over packed in moist clay or earth, as dryness is certain death to them. There are many seeds that will keep for years in a dry place without their vitality becoming impaired; but there are others, as the *Amherstia nobilis* for example, that cannot be imported or preserved for any length of time in good condition. Nature sows her seed as soon as it ripens and falls from the tree and in some cases this becomes an imperative necessity for the gardener or collector to adopt. Tubers of *Habenarias*, *Satyriums*, *Disas*, and many other of the South African terrestrial Orchids might be sent over in quantity during the resting season, packed in soil. Many of the European Orchids and rare or interesting Alpine or herbaceous plants may be sent by post, packed in a little damp moss, and wrapped in thin sheet india-rubber. Dr. Hooker recently observed, in reference to sending plants by post, that he had received living plants of a species of *Vanda* from India sent in that way. There can be no doubt of this being a convenient and inexpensive method of obtaining small parcels of living plants from abroad, when one has friends there to collect and send them.

F. W. B.

**Poinsettias.**—Some of my Poinsettias are tall and straggling; will it injure or kill them if I cut them down after flowering?—J. C. [Do not cut your plants down yet; store them under the stages or on back shelves of your stove or warm greenhouse, and keep them dry and free from drip. If under the stage, lay them on their sides and rest them until they show decided signs of growing; then cut them back to two good eyes above the soil, shake them out of the pots they are in, and repot them into 6 or 8-inch pots, in a compost of three parts yellow loam and one of leaf-mould, with the addition of a little peat and rotten manure. As soon as they become established, pinch the two shoots that push from the eyes left at the second or third joint, and do not pinch again. The tops that were cut off should be cut up into single eyes, and treated as Vine eyes, or into pieces having two eyes, one to be inserted under the soil, and the other to remain above it in small pots, afterwards shifting them into their flowering ones. These operations are best done in May or June. Both the cuttings and old plants should be started and grown on in a brisk bottom heat, in a position as near the glass as possible. Give the eyes and cuttings the assistance of bell-glasses until they have become well rooted.]

**Lisianthus Russellianus.**—I observe that one of your correspondents complains of not being able to grow this plant as it was grown in the days of "Cuthill and Green." I was personally acquainted with Mr. Cuthill when he used to grow it so well, and, when I lived in that neighbourhood, I could grow it too. Upwards of twenty years ago Mr. Thomson, of Clovenfords, also grew it well. I have been in this quarter nearly twenty years trying to grow it, but have neither been able to do it satisfactorily myself nor have I seen it done (except in one instance) by any one else. The only difficulty I have found is that I can hardly call them pretty before they become a prey to thrips, which I have never yet been able to kill without, in the end, killing the plants. Our soil appears to be quite natural for them to breed in. When I grew the plant in question, within ten miles of London, I scarcely knew what a thrip was. With a good mellow loam, a little leaf-mould, and sand according to the nature of the loam, with a dung bed or stove, and constantly stopping whenever you can do it till about June or July, I see no difficulty in flowering plants of *Lisianthus* by the August twelvemonths after sowing in March. It is a long time to wait, but well worth it, if successful. I suspect that in these days of steam and telegraph, our present race of gardeners have not the patience required to grow it well. I had some nice plants in the spring, but they are gone.—ONE OF THE OLD SCHOOL.

#### NOTES AND QUESTIONS ON THE INDOOR GARDEN.

**Saccolabium.**—I am obliged to "G." for having pointed out my little mistake in reference to *Saccolabium Holfordianum*. I think with him that it is absolutely necessary that such errors should be pointed out as soon as discovered, so as not to mislead beginners in Orchid culture.—F. W. B.

**Maranta Veitchii.**—In your correspondent "G.'s" article about *Marantas*, (p. 544, Vol. II.) he says of *Maranta Veitchii* the blade of the leaf is upwards of 1 foot long, with a foot-stalk from 12 to 18 inches in length. I have a plant here with forty-two leaves, each averaging 18 inches in length by 10 in. in width, borne on foot-stalks 3 feet long. The plant, including the pot, is precisely 6 feet in height. This plant was purchased in the nurseries about eighteen months ago, and has been grown to the above size since that time.—W. H., *Cambridge Wells*.

## THE FRUIT GARDEN.

### THE FRUITS OF ANCIENT ROME.

IN respect of fruits specifically distinct in kind from one another, the ancients were well off. Grapes, Figs, Pomegranates, Almonds, Apples, Citrons, Dates, Olives, and several others are mentioned in the very earliest pages of human history; and by degrees, in one country or another, were added Walnuts, Chestnuts, Peaches, Pears, Filberts, Medlars, Mulberries, Cherries, Plums, Quinces, and the fruit of the Service tree. As with the culinary vegetables, certain fruits also were esteemed, more or less, that in England have never been recognised, in some cases because unsuited to our climate, as Jujubes, Arbutus-fruit, and the berries of the *Cornus mascula*. Most of the superior kinds, again, like the best of the esculent vegetables, were originally from the east; the Vine, for instance, probably a native of Armenia, was first brought into Europe by the Greeks; the Fig (which being said to have first come from Caria, a province in the south-west of Asia Minor, still bears the appellation of *Ficus Carica*), the Walnut and the Peach from Persia, and the Cherry from Pontus. The Pomegranate, though a native of Asia, was brought into Italy from Carthage; the Olive was introduced from Greece, and the Pistachio nut from Syria. Others, such as the Chestnut and the Hazel nut, which was the parent of the Filbert, belong to the spontaneous flora of Southern Europe. Some of these fruits were not conveyed westwards till the Roman power was reaching its acme; the Cherry, for instance, not until B. C. 73, or when Lucullus obtained his victory over Mithridates, and carried it home as a part of his spoils. Rome, the mistress of the world for so long a period, became, through acquisitions of this nature, a point or centre for their diffusion. However selfish may be the motive for accumulation, things must needs get distributed, if anyone will take the trouble to collect. Good comes in the end even of avarice; and lateral advantage to some one, of every kind of heaping together, whether it be flowers, or books, or pictures, that are amassed. This is the true sense of the axiom that "charity begins at home;" it applies alike to nations, and to the acquisitiveness of individuals; and hence we find that some 120 years after it was first seen in Rome, or in A. D. 48, even this comparatively insignificant Cherry was carried into Britain, then an island of barbarians. To the Romans, likewise, England owes the introduction of the Vine and the Chestnut, and almost certainly, too, the introduction of the Turnip and the Carrot, Beans, the Beetroot, and their favourite Cabbage plant, for the name of "Kale" occurs in the oldest English records. In reading of the pomps and vanities of that great people the Romans, their wars, superstitions, profligacy, and barbarities, we are apt to forget sometimes how they fostered the minor details of civilization. In the midst of their conquests and cruelties, they never lost sight of the useful and beneficial arts of life, showing themselves willing learners of whatever they found new and serviceable, and at the same time dispersing their knowledge over the countries they vanquished. The benefits which they conferred were often of a nature calculated to alleviate the miseries caused by the sword; if the benefits did not appear immediately, they have, at all events, outlived the miseries, and in many instances they form the noblest monuments that remain of the ancient presence—the Chestnut to wit, and the Vine, in our own country. Take only that glorious old Chestnut at Tortworth, to say nothing of the thousand princely examples in our parks; who can be other than glad beneath its calm and antique shade? A fair and consistent man, who would do unto others in the way that he himself desires to be done by, will always ask first what good has been effected by the nation or the individual waiting judgment, and leave the objectionable and the unamiable points to the last. So governed in his spirit, he lives, at all events, in an atmosphere charged with pleasant things instead of painful ones, a matter more important than he may think, since men's own characters and capacities for happiness are coloured by the surroundings they spin, like a silkworm, from themselves.

To what extent the multiplication of "varieties," technically so-called, of any of the Romans' fruits may have been carried prior to the Christian era, is not now ascertainable. It is certain, however, that under the Cæsars, the Romans pos-

sessed of Pears more than thirty-six varieties, and of Apples at least twenty-two; those which answered to what we should now-a-days call dessert fruit, being elegantly termed Melimela or "honey Apples." Cherries they had in about eight different kinds, Figs also in variety, and a very considerable number of sorts of Plums, including one said to have been raised near the renowned Syrian city of Damascus, and thence called the Damascene. This last, judging from the epigram in Martial, had plenty of stone and very little flesh, and perhaps corresponded to the modern Prune. Whether our nineteenth century "Damsion" is a descendant of the ancient Damascene as well as heir to its name, is an open question. The Vine, being sedulously and universally cultivated, of course presented many varieties of fruit. One of the sorts had the berries so remarkably elongated that they were termed Dactylides or "finger Grapes"; while some of the varieties were adapted for being dried, as long before in Asia, into Raisins. Here it may be interesting to note that the juice of the Quince was by the Romans mingled with honey, so as to make a pleasant conserve, the antetype of our modern marmalade; the kind employed for this purpose being one that was yellow both inside and out, and thence called *Chrysomela*. Marmalade, a term derived from the Portuguese words for "bitter Apple," literally and properly designates only such a preparation as that in favour with the Romans, *i. e.*, one from the Quince *pur et simple*. The metaphor by which the name has been extended to the familiar and delightful sweetmeat manufactured from the Citrus Bigaradia is, however, perfectly legitimate; the very best of the Roman conserve was probably still inferior to the delicious dulcamara which at our breakfast tables makes us thank heaven for the Seville Orange—and for those who manipulate it. Among the fruits little cared for by the Romans, though profoundly in favour with ourselves, were Apricots, probably because of inferior sorts only, and those which are commonly called "bush fruits"—or Gooseberries, Currants, and Raspberries. These three do not appear even to have been known to them; while their acquaintance with the Strawberry was only as a wilding of the hills, or brought down therefrom, just as cloud-berries, the produce of the *Rubus chamamorus*, find their way occasionally into the fruit shops of the north of England, or as the Whortleberries of the moors where sportsmen go for grouse, come, in September, into the market places. Even at the present day, the climate of Italy is found unsuited to the generous and always welcome little Rosewort; it succeeds only upon the higher grounds, and the same is to be said of the fruit-bearing species of Ribes, which flourish, as regards countries, in inverse proportion to the Olive and Fig. Where these hardy children of the north—the Gooseberry and Currant—attain perfection, the former are exotic curiosities. Contrariwise, where the Fig and Olive prosper, the others stand abashed, turn to evergreens, and forget their language. Mounit Ida, close to the Hellespont, gave its name to the Raspberry, *Rubus Idaeus*. The fruit, however, seems to love England better than the famous eminence where the goddesses, appealing to the verdict of Paris,

"the veil divine

Cast unconfined, and gave him all their charas."

LEO GRINDON.

### GRAPE GROWING AT CASTLE KENNEDY.

THIS fine place, belonging to the Earl of Stair, in the west of Scotland, has for years enjoyed a well-merited reputation for the size and excellency of its Grapes. At the first International Fruit Show at Edinburgh, Mr. Fowler showed some magnificent fruit. Muscats and Hamburgs of from 12 lbs. to 15 lbs. per bunch, White Nice 17 lbs., and others in proportion, were something to charm the eyes and gladden the hearts of Grape growers. The bunches, too, were not only large, but the berries were also very fine and the finish perfect. Since then, Mr. Fowler has kept in the front rank among Grape growers, though at the Fruit Show in Edinburgh, in 1871, he allowed a pupil of his own—Mr. Johnson, of Glamis Castle—to run in and win most of the premier prizes. Last September, however, at the great International Fruit Show at Glasgow, Mr. Fowler again carried off many of the first prizes. "How does he grow his Grapes?" is a question often

asked. Well, I took a long journey to try and find out, and as Mr. Fowler has no secret in the matter that he cares to keep back, the fault will be mine if I do not succeed in revealing his whole art of Grape culture.

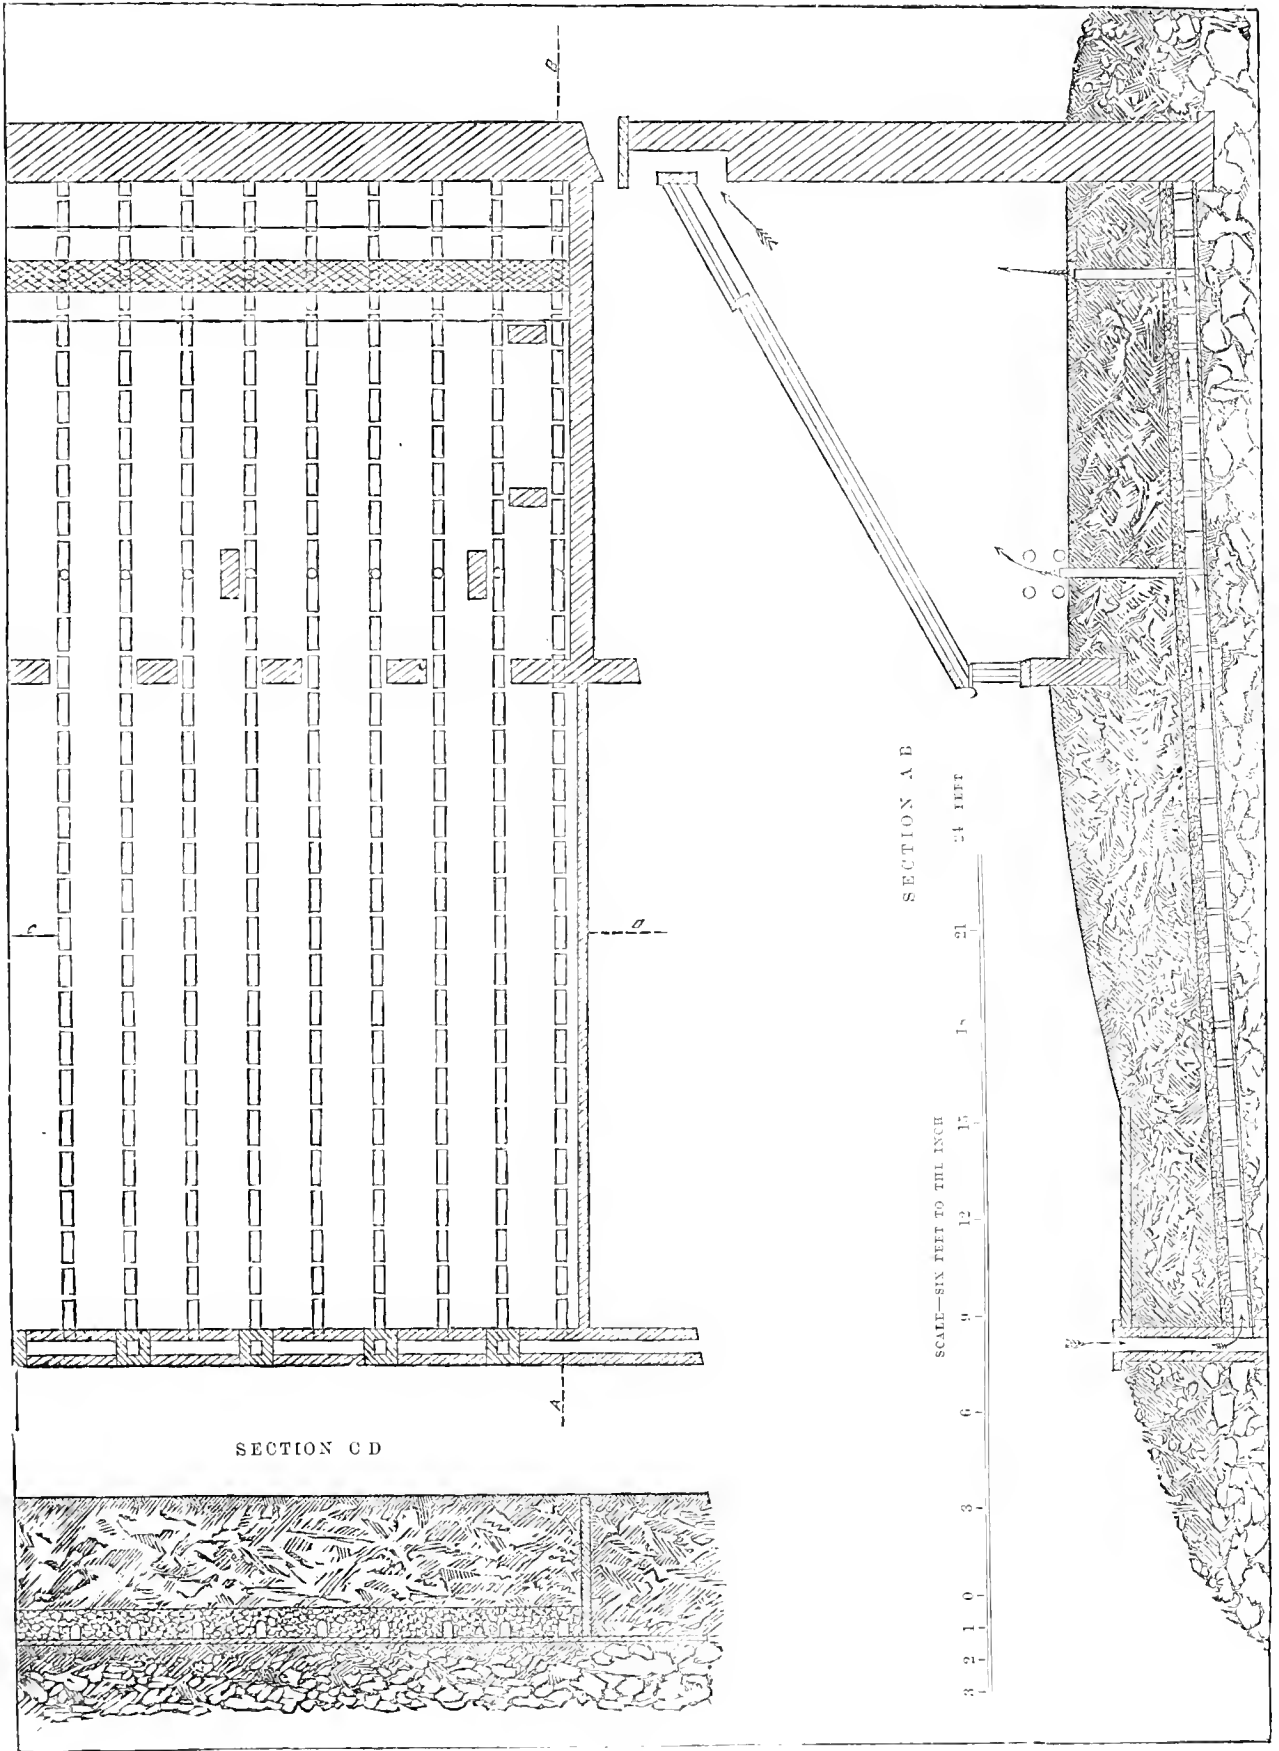

The position of the Vineries at Castle Kennedy is by no means favourable. The entire demesne is almost a peninsula, enclosed between two splendid sheets of fresh water, called the Black and White Lochs. The kitchen garden is pitched at a low level, close to a canal that connects these lochs, intermixes their waters, and keeps them at one level. The Vineries are within a stone's throw of the canal and a very few feet above its level. In such a position it is no marvel to learn that Grape growing used to be a work of difficulty. The Grapes kept the gardeners in hot water—in revenge, probably, for their roots being kept so near to the cold. Gardeners there could succeed in other matters, but most of them failed, more or less, in Grape growing. The most brilliant prospects were wrecked again and again on the road from "show" to finish. The growth was strong, the "show" promising, the first swelling free; and then came the stoning, colouring, finishing—no, not the finishing; that consisted of nothing but shanked red berries. When Mr. Fowler took possession, under a former Earl, he was informed that if he could grow good Grapes—well; if not, he must go the way of former gardeners. Such instructions would have intimidated many young men; they only, however, served as a stimulus to action in the case of Mr. Fowler. A glance at the situation suggested the probable remedy; the Vine roots must be got up and kept out of the water.

It is, however, a singular fact that many of the best Grapes in the country—those at Trentham, Chatsworth, Drumlanrig, and Castle Kennedy, for instance, are grown within a few feet of the water level; and I have heard the excellency of the Grapes in most of these places attributed to their near proximity to the water. This is, however, the very opposite of the truth; for I believe in all these places the roots are either tempted out or forced out of the water by artificial expedients, and the Grapes largely owe their superiority to the skill and success with which this is done. Even aeration, as Mr. Fowler's first experiments proved, will not suffice if the roots are permitted to reach water mark. The concreting or building out of Vine roots from cold subsoil and colder water has long been a favourite practice with the best cultivators. Where the water is lower down or the subsoil less ungenial, deep drainage, or the artificial elevation of Vine borders above the surrounding surface has been adopted as short cuts to the same end, viz., the enticing the roots to the surface and keeping them out of the water. In addition to this various attempts have been made to aerate the entire border by means of a layer of rubble or coarse stones resting upon a network of drains, rising to the surface at both ends, to open or shut at pleasure. It is obvious that by some such expedients a good artificial root run may be formed for Grape Vines, or for other trees in any situation, even over a marsh, a lake, or a sea of mud. With pillars to support an artificial base of stones, a good border may be made above, wholly independent of what is below. By rendering the bottom impervious to roots, and giving it sufficient pitch to prevent water from lying upon it, we may begin *de novo*, and form the border of whatever we choose it shall consist. This is exactly what Mr. Fowler did. The foundations of his new borders were laid in two inches of solid concrete, forming a sharp, impenetrable dividing line between the old earth and the new borders. All on the upper side of the concrete was for the Vines; all below it was forbidden ground. Having made the border impenetrable, the next point was to lay it dry. This was effected by forming a capacious drain in front, at a lower level than the concrete, and covering the surface, from front to back, with rows of 4-inch drain tiles, at intervals of 2 feet. The spaces between the tiles, as well as a few inches over them, were then filled in with stones, using the largest ones at the bottom, set on edge as hollow as possible, and the smaller ones at the top, with a surfacing of gravel, the whole porous mass averaging 8 or 9 inches in depth. An inverted turf shuts the door of the drainage against the soil of the border, and preserves it perfect for many years. The soil used was good maiden loam mixed with turfy fibre, enriched with a

liberal sprinkling of inch bones, and about one load of lime rubbish to ten or twelve of loam. This was all—no manure nor nostrums of any sort. Neither is there any charm in the depth or width or form of either the borders or the Vineries. Both are wide; the houses rather lofty, and the borders of an average depth, the surface being rather more sloped than the bottom, as will be seen on an examination of the accompanying illustration.

So far the borders vary little, if at all, from thousands of others. Thorough drainage, fibry loam, lime debris, inch bones, roots near the surface, are universal items in Vine borders. Well may doubters ask is there nothing more?—no better instruction than this to be got at Castle Kennedy? There is, and it is this: the importance of ventilating the earth in which the roots live, as well as the atmosphere in which the tops grow. This is the secret as regards success, if there is one to be found at Castle Kennedy or elsewhere. The lines of drain tiles carried from the water drain in front to flued or pigeon-holed drain inside the Vineries, are neither socket pipes nor laid end to end, but placed 2 inches asunder, as will be seen on reference to the plan (C D). Then at intervals along the water drain square hollow pillars or shafts are carried up above the surface furnished with hinged lids, to be opened or shut at pleasure. Other two drains come to the surface inside the Vineries, one under the front pipes, the other under the grating at the back of the house, as shown in the section. All these can be opened or shut at pleasure. In general terms the outside one may be shut in cold weather and opened in warm, and early in the season they are shut at night and open in the day; whereas in summer and autumn they often remain open night and day. They are seldom opened till March, opened by day and shut by night till July, and left open till October. There might seem to be little advantage in these arrangements, and in fact, little or no circulation of air through the drains or borders. It is, however, quite otherwise. The air passes freely through the drains into the house, and not infrequently a reverse motion is also observed from the houses into the drains. The proper working of the drains doubtless largely depends upon the taking of the house atmosphere into partnership with them. Singly and alone the drains would neither aerate nor warm the border much, if at all. In fact I have seen a similar system of drains, one end terminating outside the house, and the other coming from the front of the borders, resulting in a total stagnation of air. So placed there was not sufficient disparity of temperature between the two shafts to disturb the equilibrium of damp stagnant air beneath. But bring up the air drains in close proximity to the hot-water pipes, or even under the gratings of a warm Vinery at work, as at Castle Kennedy, and the drains begin to work at once. Even in September, when the difference between the external and internal atmospheres was at a minimum, the draught from the gratings at the back agitated a paper held near them. Of course the greater the disparity between the external and internal atmospheres the more rapid will be the circulation. As a system of ventilation by which a constant change of air is provided without draughts, I consider these air drains worth ten times their cost. By leaving, as is mostly done at Castle Kennedy, more or less air on always at the top of the Vineries (as will be seen in the section), a stagnant or effete atmosphere becomes impossible. It would be difficult, indeed, to over-estimate the importance of the passage of so much air, not only through the drains, but also through the entire substance of the border, the temperature of which is thus sensibly raised several degrees higher than it otherwise would be. The influence of so much genial air upon the texture of the borders is perhaps equally, if not more, important than the increase of temperature. The soil continues sweet and porous for years, and at all seasons it is filled with healthy rootlets active in quest of food.

The reason why so many young Vines thrive so well in most places at first is because the new borders are aerated in the best sense of the term. The turfy loam is permeable to air in all directions, and the roots run into it freely. By-and-by the fibres disappear from the loam, the mass gets consolidated in spite of the hard matter mixed with the earth, and then follows unwholesome growths, shanking, and other evils to which Vines are liable. Aeration seems to

SECTION C D

SECTION A B

SCALE—SIX FEET TO THE INCH

VINE BORDERS AT CASTLE KENNEDY.

prevent these. The borders at Castle Kennedy, after twelve or sixteen years, are as sweet and full of roots as ever. There are no annual root rottings by the rains; no seasons of sour sterility or partial and total paralysis or arrestment of vital action. On the contrary, root growth seems continuous, and the supplies for the Vines, in all stages of growth, seem ever in advance of the demands. The possibility of a back action of air from the Vineries to the borders has already been alluded to. There is no doubt that this occasionally takes place, and doubtless a great portion of this heat is also sent up through the border. The air that comes through from the outside is likewise well charged with moisture in the drains before it enters the houses, and the constant supply of fresh moist air is insensibly, as it were, brought in.

Some have objected to this mode of aerating Vine borders, on the ground that the drainage would be excessive in dry weather, and that the hot dry air, passing in and through the borders, would lick up any moisture that remained, and thus create a water famine. Opposed to these objections may be placed the watering pot and hose, and shutting down the lids of the drains. There is no more reason that we should use them during severe drought than when the thermometer is at zero, and thoroughly drained Vine borders often need a thorough soaking, whether aerated or not. Besides we are not obliged to use a power we do not want merely because we happen to have it. Wherever aerated Vine borders have been fairly tried they have succeeded admirably. Mr. Fowler has planned such borders at Glamis Castle, Sir W. Wallace's, Carrigorman, and elsewhere, and in all cases they have given the utmost satisfaction. I do not say that by aeration alone superior Grapes may be grown: great care, skill, and ability have doubtless much to do in achieving success. But this much I know, that whereas clever men grew Grapes at Castle Kennedy little larger than white Currants, we have seen bunches from the same gardens over 17 lbs. in weight, and with berries approaching the size of Damsons. Hence it follows that Grapes of the highest excellence may be grown on well made aerated borders. Mr. Fowler does not expend the strength of the Vines on a few monster bunches; on the contrary, he takes a full crop every year. The Vines are in robust health, by no means young, and look like doing in the future as well as they have done in the past. D. T. FISH.

**Vitality of Fruit Tree Cuttings.**—The report of the Horticultural Society of the colony of Victoria gives some facts proving that scions and cuttings retain their vitality much longer than has been generally supposed. The Society had a case of fruit tree cuttings forwarded to it from Chiswick. These cuttings were from among the prunings taken off in October. They were forwarded in December, and reached Victoria in about six months after they were cut from the trees. On their arrival in April, "there being no stocks in condition for grafting," they were kept over for another four months, or until the following August, when they were worked. Thus, more than three quarters of a year elapsed from the time the cuttings were taken from the parent tree at Chiswick, until they were used as scions at Victoria; but notwithstanding the delay, the result is, that out of the consignment, five Vines, eight Plums, twenty-four Figs, sixty-six Apples, and seventy-two Pears have been saved. The importance of this fact is not to be overrated.

#### NOTES AND QUESTIONS ON THE FRUIT GARDEN.

**Two Varieties in one Apple.**—Professor Asa Gray reports receiving an Apple from the Smithsonian Institute gathered from a tree of Spitzbergen which was on the surface one half Spitzbergen and one half Russet. A tree of the latter fruit stood about 200 yards off. Several cases of this sort are known, in which, as in this, the division is into two exactly equal parts of the circumference, the line of demarcation being abrupt.

**Ill-ripened Peach Shoots.**—One of the surest indications of imperfectly ripened wood is the pushing of the leaf-buds, simultaneously with the flower-buds. When the wood is hard and perfectly matured, the flowers always open first and freely, and are large and of good substance; but when the leaves push hurriedly at the same time they should be pinched clean back to the germ again with the finger and thumb, otherwise the flower-buds, after pushing a certain length, will stop and eventually drop off without opening. In pinching the leaf-buds back, care should be taken to do it in time—in fact, as soon as the point of the bud can be got at with the finger nails; but the base of the bud should be left, and it will not fail to break again. Sometimes it is necessary to pinch twice. This practice will often ensure a good "set" of fruit that would otherwise be a failure.—S.

## GARDEN DESTROYERS.

### THE OAK-LEAF ROLLER.

(TORTRIX VIRIDANA).

THE Oak has many insect enemies, some of large size and very destructive; but the tiny little moth of which we are about to give an account makes up for its minuteness by its numbers, and does as much mischief as any of them. Fortunately it is not always, nor even very often, that it appears in such great numbers as to do serious injury; but it is always with us in sufficient abundance, and not rarely in too great abundance. The perfect insect (Fig. 1, c) is a lovely little moth with the fore wings above of a uniform pale emerald green with the anterior margin whitish or yellowish; the hind wings are pale grey with a white fringe. The size is indicated in the above woodcut. The caterpillar (Fig. 1, a) varies from lead coloured with a greenish tinge or a dirty greenish yellow to a rich dark green. The head, a plate or shield on the first segment, the feet, and a quantity of little dots, from which a stiff hair springs, scattered over the body, are all bright shining black. The chrysalis (Fig. 1, b) is black or brownish-black, and has a double row of small spines on the margin of each segment. Its life history is as follows:—

Under normal circumstances it feeds exclusively upon the Oak; when hard pressed it may occasionally take to other trees. In some parts of Germany, in 1838, when the Oaks were totally destroyed by frost, it took refuge in the Ash trees, which had suffered less, and changed to the chrysalis in their rolled up leaves, but unless under such exceptional constraint it confines itself to our two indigenous varieties of Oak (*Quercus pedunculata* and *Quercus sessiliflora*), a fact which we may incidentally remark strengthens the view that these two so-called species are only varieties of the same tree, and it is said to give the preference to the former because it is usually first in leaf. It has been observed that the American Oaks, although growing close beside our English Oak, have not been touched by it, while the latter have been defoliated. This peculiarity it may be well for Oak lovers to remember, especially if they reside in a district which suffers from the presence of this insect. The eggs are laid in the end of summer or in autumn and remain dormant throughout the winter. Some difference of opinion has existed among observers as to the place where they are laid, some stating that they are simply glued on to the bark in the neighbourhood of the eyes which are to come out as buds in spring, others holding that they are in some way introduced into the bud itself. There is something to be said for both views, but the structure of the ovipositor of the female moth seems to settle the question. It has no apparatus for piercing substances of even moderate hardness, and we therefore go with those who say that it glues its eggs upon or about the embryo buds of next season. As soon as the eggs are hatched the young caterpillars commence upon the young buds, and make their way into the interior, a circumstance which, together with the sickly appearance of the bud into which the grub has entered, has given rise to the idea that the eggs are deposited in the bud. Ratzburg has observed, for instance, that when he has caught the caterpillar in the bud at an early stage, before it had eaten much, it lay close under the outer scale in a fine web surrounded by atoms of debris. This, however, is not inconsistent with either view. They do not, however, long remain in the bud; as soon as the leaves are out, which is usually before they have eaten farther into the bud than through the two outer leaves, they leave it and take to the expanded leaves, and one of their first steps is to make themselves houses by rolling up the leaves like empty cigaritos. They affect no particular form for the roll, sometimes rolling it up transversely, sometimes longitudinally, and at other times obliquely.

The process of rolling it up and tying or strapping it up in the position it is to maintain is very curious. Those of our readers who are accustomed to a country life, or who even only now and then pass a few days in the country, must have often seen leaves so rolled up, but probably few have taken the pains or had the patience to watch the process, and yet if they will think a little how they would set about to do it themselves with the simple means that the caterpillar has at its disposition, we imagine that they would give it up as a puzzle that

they could not solve. It is all done by the judicious application of straps. The only appliances or apparatus which the caterpillar has are its own weight and a reservoir of glue or liquid silk in its salivary glands, which is adhesive at first, but rapidly hardens when exposed to the air. This it can draw out as a thread of silk by allowing a drop of it to stick to any point, so that on drawing back its head the silk is drawn out of its mouth as a thread. With this simple machinery, it rolls up the leaves in all the various modes in which we find them.

There is, however, one requisite without which it cannot get on at all, and that is a certain amount of curvature in the leaf before it begins. If the leaf were perfectly flat it might strap it as it liked, and would never get it out of position. But given the smallest bend, it has a lever to act on, and the difficulty is over. It attaches a thread on one side of the curve of a concave part of a leaf, then tossing its head to the other it fixes it there: then passes it back, and wagging its head to and fro fixes it alternately on each side by a simple touch. It thus gradually makes a broadish flat strap, consisting of many threads stretching over the hollow of the bent leaf and ties the opposite walls of the curve together; that fixes a certain amount of curve to start with. But how is it to get it further bent? Simply by repeating the operation, but this time obliquely over the first straps, and as in doing so it rests its weight on them, that causes them to sink a little, and brings the points of attachment a little nearer, and that increase of nearness is secured and maintained by the second set of threads or straps.

As the breadth of the roll increases, the number of separate and independent straps is increased too. This process it

The Oak-leaf Roller.

repeats again and again, until the leaf is rolled up as much as it desires. When a stiff, unbending nerve or midrib stands in the way, and refuses to bend, it cuts out a little bit here and there from the rib, exactly as a carpenter saws half through a lath that he wishes to bend, and thereby makes it yield to the extent desired. After the roll is complete, the caterpillar uses it both as its house and larder. Being provided with an opening at each end it has a ready mode of escape from intruders, and it can feed both inside and out; and as one leaf is not sufficient food for the whole life of a larva, which may eat four or five, it either has recourse to neighbouring leaves, retiring to its house as a castle of refuge when necessary, or, if a new house becomes necessary, it recommences the process of rolling a new leaf. As in all insects that spin cocoons or line their abodes with silk, so with these the flow of silk from the salivary glands becomes greater as the period of passing into the chrysalis approaches. Then they seem to have more than they know what to do with. They are then found hanging in numbers by threads from the trees; webs may be seen on every side, and numbers of them may be found spinning them in common, enveloping leaves and twigs together in a white silken covering.

The larva usually passes into the chrysalis in the rolled leaf, the interior of which it then lines with silk, but sometimes out of it in crevices in the bark, or in the brushwood. It is to assist the perfect insect in emerging out of the rolled leaf that the chrysalis is provided with a double row of little spines at the margin of each segment. By means of these it wriggles forward to one of the mouths of the rolled leaf, so that when the perfect insect emerges it has only to step out of the roll into the open air; and, when the insect has changed into the chrysalis, in its roll, we can see the black hulls of the chrysalis

protruding at its mouth, after the flight of the moth. The perfect insect comes out towards the end of June, and at that time, by beating the branches in woods infested by them, they can be knocked down in showers. They lay their eggs chiefly on the topmost branches, at least we may infer this from the topmost buds being especially attacked, and sometimes quite full of caterpillars, and from the tops of the trees being first denuded of their leaves. When its ravages are severe, whole forests are denuded of their leaves, so that they look as if struck by lightning. The effect of denuding the tree of leaves is of course to retard its growth, and, if repeated often enough, to kill the tree.

This species occurs in Britain, France, Belgium, and Germany, wherever the Oak abounds. No satisfactory remedy or prevention for its ravages has yet been found. Bechstein proposed to set fire to the caterpillars hanging by threads, and then to crush them. Ratzeburg suggested gathering the chrysalids by sweeping down the rolled leaves by a strong broom or rake to the foot of the tree, and then destroying them *en masse*. But neither plan seems very practicable. Boisduval regards the increase of small birds as likely to be beneficial, and in support of this recommendation mentions that the insect was less numerous in the forests of Senart, St. Germain, and Fontainebleau, than in the Bois de Boulogne, where, of course, small birds were scarcer. Ratzeburg attaches little importance to the efforts of birds, because when the ravage is at its worst, he says they are then breeding and retire into the woods; but still they have to be fed, and general opinion, we think wisely, now recognizes their importance.

It has been observed that whenever any species is increasing in disproportionate numbers, some enemy, parasite, or destroyer increases in a proportionate degree. This is the case with the ichneumons and parasites that feed on the Tortrix viridana. On some occasions when they were numerous Boisduval found that out of a large number which he attempted to rear the one-half had been rendered abortive by ichneumons. But for some such check there would seem to be no limit to their increase, for they are so ingeniously protected by their rolled leaf that neither birds nor other enemies, rain nor cold can get at them. The only weather that seems to reach them is heavy rain for some days in warm weather, just when the caterpillars are coming out, and before they have got their houses made. Frost they can stand, unless it were to be so late and severe as to destroy the leaves on which they feed. As one fire burns another out, so sometimes the cockchafer starves the caterpillar to death by eating up all the leaves, but this is no satisfaction to foresters, who have no preference for one agent of mischief over another. A. M.

**Woodlice.**—By the following very simple method, frames and pits might be kept comparatively free from woodlice; at any rate the insects might be so far subdued by it as not to be injurious to plants. Put a cold boiled or roasted Potato into a small flower-pot; cover the Potato with moss, leaving a little hanging out of the pot by way of enticing the insects to enter; then lay the pot on its side in a corner of the frame. Woodlice feed in darkness, and at the approach of day they trot off to their hiding-places in cracks and crevices, or amongst the loose soil or bark; the moss is, therefore, necessary to induce them to remain in the pot, to which they will flock in hundreds, after having once tasted the Potato. Every morning the pots should be taken out of the pits and the insects destroyed. The same bait will serve for a week or longer. If properly attended to, half-a-dozen pots so prepared will soon clear a frame of this troublesome insect. Another plan is to pour boiling water round the sides of the frame or pit, taking care in doing so, however, not to injure the roots of plants.—J. M. H.

An old physician was declaiming, in our hearing, the other day upon the propensity which a majority of people display for eating unripe fruit and vegetables. Said he, "There is not a fruit or vegetable growing in our gardens that is not best when arrived at maturity, and most of them are positively injurious unless fully ripe."—"I know one thing that ain't so good when it's ripe as 'tis green," interrupted a little boy, in a very confidential, but modest manner.—"What's that?" sharply said the physician, vexed at having his principle disputed by a mere boy. "A Cucumber," replied the lad. The doctor winked at us with both eyes, but said nothing.

THE FLOWER GARDEN.

SOUCIET'S NEW GLADIOLI.

MONSIEUR SOUCIET, of Fontainebleau, who is unusually successful in the cultivation of Gladioli, has again raised some new kinds, remarkable for their size and perfection of form, as well as for new colours. Among them, the following will be found desirable additions to any collection, viz. :—

**Addison.**—Spike large; flowers very large and of a deep amaranth, striped with white. A lovely plant of middle height.

**Benvenuto.**—Spike long and striking; flowers very large, much open, of a pink or pale orange colour, very brilliant and transparent, spotted with white. Plant of a middle height.

**Elvire.**—Spike long and fine; flowers large and pure white, edged with carmine. Plant middle height.

**Eva.**—Spike ample; flowers large, ground colour white tinted and shaded with rose and pale lilac. A fine flower. Plant of middle height.

**Figaro.**—Flowers large and open, rose or reddish-orange, tinted with a deeper shade, and having large spots of pure white. A grand plant.

**Le Phare.**—Spike very long; flowers large, brilliant bright red and very open. Plant medium height.

**Lulli.**—Spike good; flowers large and perfect; bright cherry slightly tinted with orange; ground colour clear, the inferior division striped with carmine. Plant of middle size.

**Macaulay.**—Spike long and splendid; flowers large, deep crimson slightly tinted with violet and spotted with deep carmine; centre clear and transparent. Plant of middle height.

**Margarita.**—Spike very long; flowers large with a white ground tinted with carmine. A strong growing and beautiful variety.

**Octavie.**—Spike long; flowers large, of a pretty pale pink, slightly edged with red, and lined and spotted with pure white; centre very clear. A low growing variety, but one that is exceedingly beautiful.

**Reine Blanche.**—Spike very long; flowers beautiful; pure white with small spots of deep carmine.

**Venus.**—Spike very long; flowers large; pure white flushed with pale pink. A splendid variety of middle height.

E. A. CARRIERE.

ROSES SUITABLE FOR A SMALL GARDEN.

Would you kindly name the best kinds of Roses for growing in the West Riding of Yorkshire. I should prefer those that smell the sweetest. Is not there a very dark climbing Rose called "Old Fulgens?" Would you please include about a dozen names of the best climbers. J. W. R.

[The following are recommended by Mr. George Paul as a good selection for anyone requiring a collection of about sixty kinds :—

--	---	---

The York and Lancaster Rose (*Rosa versicolor*).—Parkinson, in his "Garden of Pleasant Flowers" (1656), thus describes this Rose :—"In the form and order of its growing, *Rosa versicolor* is nearest to the damaske Rose, both for stem, branche, leaf, and flower. The difference consisting in this, that the flower hath the one-half of it sometimes of a pale whitish colour, and the other half of a paler damaske colour than the ordinary; this happeneth so many times, and sometimes also the flower hath divers stripes and marks in it, as one leaf white or striped with white, and the other half blush or striped with blush; sometimes, also, all striped or spotted over, and other times little or no stripes or marks at all, as nature listeth to play with varieties in this as in other flowers." The same author states that the damask Rose "is of the most excellent, sweet, pleasant scent, far surpassing all other Roses or flowers, being neither heavy nor too strong, nor stuffing or unpleasant sweet, as many other flowers." The shoot and leaves figured in Parkinson's book show this to be a variety of *Rosa damascena* of Miller, and as its flowers agree with the description, there can be no doubt that it is the true York and Lancaster Rose, a name now generally applied to the *Gloria Mundi* Rose, which is a variety of *Rosa gallica*, or French Rose.—W. GORRIE.

**Two desirable Outdoor Plants.**—Now that the majority of people are beginning to think what flower seeds, &c., they are going to buy for the ensuing season, may I be allowed to suggest two flowers, which will, I think, please anybody who tries them. The first is *Bidens atrosanguinea*, a flower I have never seen anywhere but in my father's garden. We raise the seeds in a warm frame, and plant out the young plants at the same time as we do Asters. The flowers are of a very rich maroon or chocolate colour, and resemble somewhat a single Dahlia. Mixed in a bouquet they form a charming contrast to any white or yellow flowers. After flowering we take up the roots, which are very like those of a Dahlia, and treat them just the same as we do those of that flower. They like a good rich soil. The other flower I would suggest is the beautiful and fragrant white Evening Primrose (*Eurothera marginata*). We got this in the form of a plant from Messrs. Baekhouse last year, and were quite charmed with it. It is, I think, quite as good a white as the *Eucharis amazonica*, though of course not as strong in texture. It has done remarkably well with us, planted on a mound of rich soil, with plenty of room to ramble about. The latter it must have, as its spreading propensity is extraordinary. Any lover of flowers will appreciate the beauty of this *Eurothera* when he finds it just opening on a still warm evening in summer.—J. H. DONALD.

**Myosotis dissitiflora.**—I have never known this beautiful plant so early as this year. On the 20th inst. it was bursting into flower all across patches 6 inches in diameter. The opening blossoms were also all blue—an unusual circumstance with the first blooms. Two frosts—ono of 3 and the other of 9—have occurred since then. These have changed the flowers from blue to pink. I observe that "A." at page 30, writes that this plant should be propagated from seed only, and that no reliance should be placed on old stools. I agree with the latter half of the sentence. Old stools only form a sort of couch for the rain and the dew to nestle upon, to the partial or complete destruction of the crown of the plant, perhaps the whole of it. But there is no logical nor necessary connection between the abolition of old stools and the raising of plants from seed only. Every leg of the stool, that is, each shoot or branch, will make an independent plant, equal in health, size, and beauty to the best and healthiest of seedlings. Take, for instance, each shoot, either with or without roots, and plant it either in a cold frame or shady border up to the leaves, and it becomes a plant in a very short time. If short of plants, repeat the sub-division again and again up to the middle of August, and thus multiply it to any extent. I have no objection to seedlings if you can be sure of getting the stock pure; but as one of the largest growers of this lovely gem, I must affirm that cuttings and divisions are equally certain, successful, and often a more rapid means of increase; and, moreover, that plants so raised flower as freely and grow as well as plants raised from seed.—D. T. FISK.

NOTES AND QUESTIONS ON THE FLOWER GARDEN.

**Thymus Serpyllum.**—I have a variegated variety of this Thyme much in the wily of Fisher and Holmes' beautiful Thyme, only, of course, much smaller in all its parts. The colour is very similar. I have also a golden self-coloured variety of *T. Serpyllum*; both will make fine rockery plants. From their close growth and hanging habit, they are well calculated to run over the dry surfaces of anything used in rockeries or dry banks.—W. ELLIOTT, *Beechmont*.

**Wallflowers.**—The dark crimson Wallflowers of the metropolitan market gardens are now coming rapidly into flower, and bunches of them have been cut and sent to market occasionally during the last few weeks. This strain of Wallflower is the earliest of any. Seed sown of it in March and April produces plants so dwarf, branching, and even in growth that an acre of them looks as though the tops had been cut level with shears. This Wallflower furnishes rich masses of colour in spring, and should, therefore, be in every garden.—A. D.

## A NATURAL CONSERVATORY.

OVER vast regions, in every latitude, the vegetation is so sparse or so monotonous that scenes deserving of the above name are rare, yet when the country is fertile in plants, and varied in surface, we sometimes find them in abundance. In the Alps, for example, scenes of beauty unmatched in gardens are often met with, not only where the Alpine flowers are the only vegetation, but also in the woods and copses. In California, too, the mixture of gigantic Pines with glossy Evergreens, both set in a sea of Lilies and other bulbs, and brilliant annuals, causes much of the hill country to be what might be called a magnificent conservatory. Intense heat or drought are of course as likely to lead to barrenness as great cold, and in the tropics, as in colder lands, the country is often dreary so far as vegetation is concerned; it depends therefore entirely on the vegetation whether a country be dreary or the reverse. In moist parts, however, the beauty of the

**Neilgherry Cinchona.**—The question of growing Cinchona at a profit in various parts of India appears to have reached a very promising stage, in spite of the drawbacks incidental to most experiments of the kind. Mr. M'Ivor, superintendent of the state plantations in Southern India, lately informed his Government that large harvests of the bark might now be reckoned upon, and advised the sending home of not less than 25,000 lbs. as a first consignment, to be sold by public auction, with a view to test its quality and market value. It is still open, we believe, to question how often the same trees can be stripped of their bark without injuring the quality of the yield, and many predict some kind of deterioration in the trees themselves. Canker also has for some time been at work in several plantations on the Neilgherry and Sikkim Hills; but its ravages seem to be confined mainly to plantations grown on unkindly soil or in climates more or less unsuitable. The *Darjeeling News*, however, speaks with perfect confidence of the results already attained in the Sikkim Hills. It declares that the bark grown there "could be sold with a fair profit at prices which would be ruinous to the producers

A Natural Conservatory.

vegetation is often of a kind of which those who know cold countries only can form no idea, and conservatories of beautiful plant-life are common enough. Our illustration shows a scene in which the vegetation, doubtless from the abundance of water, is luxuriant, and the grouping of diverse types particularly happy. As the flowers of the numerous climbing plants and other humbler types of vegetation cannot be rendered at such a distance, the little picture depends for its charms on the outline of the larger subjects alone, and it shows forcibly the value of form in a picture of this kind. It affords, indeed, quite a lesson as to the effects to be obtained by a little bold variation in the way of form. Take away the Palms, large Arad, &c., and leave only the smaller-leaved tropical types, and the scene, though picturesque, becomes little different in aspect from one common in every northern country.

in any other country where it is cultivated." In South America, where the mere cultivation of the plant costs nothing, the cost of carriage to the sea-coast tends to check the export trade whenever a fall in the market price occurs. In India the extent to which Government once carried experiments in growing Cinchona is said to have frightened a good deal of private enterprise out of the field; but the few speculators who hold on in spite of every hindrance may now expect to "enjoy a golden harvest," after some ten years of anxious waiting. While the private gardens on the Neilgherries show little chance as yet of winning back the sums laid out on them for years past, it is reckoned that the Darjeeling planters will soon be reaping a dividend of 30 per cent. As no return, however, can be expected from a Cinchona garden for the first eight years or so of its existence, none but capitalists are likely to embark in a venture which demands a good deal of ready money combined with a very large stock of human patience as well as cultural knowledge.

## PUBLIC GARDENS.

### CO-OPERATIVE PARKS.

WE find the following interesting article on a very important subject in the *American Gardeners' Monthly*:—"In connection with recent experience in Europe and America, we expressed our opinion a few months ago that neither at private hands nor from public bodies did we expect more than exceptional specimens of high art in landscape gardening. The American man—the average man—will regard his pleasures as well as his business, from a monetary point of view. And the American people, adopting the vicious principle that politics is a battle for power, and that 'to the victor belongs the spoils,' must have 'rotation in office': and landscape gardening, being essentially a thing of years, and not of days, cannot exist to any great extent under these accidental or quadrennial terms. But there are thousands of persons in our community who perceive these things as clearly as we do, and who delight in high art in gardening none the less for our social difficulties in the prosecution of the taste. All our public librarians tell us that the number of landless dwellers in cities and large towns who take out works on gardening and landscape art is truly astonishing; and the publishers of horticultural magazines can tell a similar strange story as to the large list of people who, without either garden or farm, are yet to be counted among the most zealous of their subscribers. These people would be the most enthusiastic in behalf of our beautiful art, if they could practise the taste without endangering their real estate speculations, or spending more money on it than their means will permit. For this large class, the plan of co-operative parks and gardens affords golden opportunities; and we presume nothing has prevented extensive application of the principle but the lack of minded men of sufficient perception to understand this innate love of citizens for garden art; or, if perceived with sufficient judgement, to employ the person to design and oversee the work.

Philadelphia has been fortunate, of late years, in having, on the management of her three leading railroad lines—the Pennsylvania, the Reading, and the Philadelphia, Wilmington, and Baltimore—men of high scientific and refined artistic tastes, conjoined with eminent business capacity. These men understand, it seems, how much can be done in landscape gardening for this large and increasing class in the community; and are laying out, in various directions about the city, beautiful tracts in the highest style of art, and selling the lots in connection with these beauty spots in such a discriminating way that even the man with an income of but a thousand dollars a year, may have not only a home in the country, but such a home surrounded by the treasures of nature and art, which, but a very few years ago, it would have been presumptuous for any one but a millionaire to aspire to. Among the movers in these enterprises, the Philadelphia, Wilmington and Baltimore Company is occupying a front rank. The original idea of a railroad was to connect two separate communities, and this line especially acted so strictly under this construction, that the road led through the cheapest ground, without regard to any other consideration. Beautiful sites were, of course, ignored; and the road was run through a level, marshy tract, which, if it were not for an occasional glimpse of the beautiful Delaware, might serve to discipline any one who rode over it, as thoroughly as a hair shirt would have done an ancient anchorite. To remedy this the present board have changed the whole track, taking it through the high ridge which runs parallel with the Delaware a mile or two from its banks from Philadelphia to Chester; and laid off, at convenient distances, park towns along its line. The road being just finished, an opening trip was recently afforded to the editors of the leading Philadelphia papers, and a stoppage of some time at the chief park, Ridley, gave us an opportunity of noting some of its leading features. The plot occupies six hundred acres, and is diversified by a continuous succession of hill and dale, through which numerous creeks and water-courses meandered to the Delaware, which was, at this point, about three miles away, and at this time bore on its bosom numerous vessels, bound for the city, six miles above. The company has been extremely fortunate in securing the services of Mr. Robert Morris Copeland as landscape gardener and chief engineer; who, as the author of 'Country Homes,' is well known and esteemed by most of our readers. Mr. Copeland has taken advantage of these valley streams to make large and beautiful lakes at points where their margins form outlines of great beauty, without any other labour than throwing a dam across the foot of the projected lake. These dams are arranged as waterfalls—not as we often see mere mockeries of natural ones—but waterfalls as natural and beautiful as any wild nature can boast of. These lakes and falls are to serve other purposes besides boating, fishing, and attractive beauty. They will be the water reservoirs of the projected town. It is but one year since the undertaking was commenced, and the chief work has,

of course, been road making. These roads are some of them straight, some curved, just as the peculiarities of the surface or landscape effect required. In various parts of the tract small portions of from one to several acres are set apart for the public parks or gardens; and these, with the roads, belong to the whole people of the settlement, in common. In order to maintain these public portions in the highest conditions of landscape gardening art, one-fifth of all the purchase money is set apart as a fund to be held in trust by the railroad company perpetually, the interest of which is to be used for the purpose. The lots are of all sizes and prices, from 200 to 2,000 dollars, while the railroad company conveys to and fro passengers and material for a considerable period to all who build. It is easy to see how such projects as these must succeed. They are born of the necessities of the times. To all intelligent people it is no mere poetic fiction that God made the country and man made the town. The only wonder is that it has not been reduced to practical prose long before this.

"The company prepared an elegant entertainment for its guests, at the conclusion of which the party returned to Philadelphia, all, we believe, well satisfied that the idea of co-operative parks was destined to solve the great problem of how the American people may live near to business and yet in the midst of the highest efforts of garden art, without being borne down by the weight of private expenses or public taxation."

## THE KITCHEN GARDEN.

### THE SEASON—SHELTER.

THE sudden fall of snow which we have had is another proof of the fickleness of our climate, and of the necessity of watchfulness. The advantages of a sheltered over an exposed situation for early vegetable crops is much felt in cold, windy weather; even the shelter of a straw-thatched or furze-drawn hurdle, to break the force of the wind, is of greater advantage than the inexperienced would give it credit for. Let us imagine you have at the corner of a house or in some other exposed situation, a bed of Roses or some choice evergreens which are always cut by the winds. Place to the windward of them a hurdle, or a few stakes, drawn with evergreens, through which the wind must be sifted before it gets to the plants, and the chances are you will have no further cause for complaint. The success which attends the labours of the great market gardeners, through covering their early Radishes, Potatoes, Rhubarb, and other crops with a light shelter of straw every evening is well known. Some, indeed, use that kind of covering by the acre. I am acquainted with one cultivator who grows from thirty to forty acres of early Potatoes annually, all of which, after they are through the ground, are protected nightly by a scattering of straw. This is taken off in the morning and returned at night, and if the day is exceptionally cold, it is left on all day. The philosophy of this is that the heat accumulated by means of the sun's rays during the day is intercepted in its radiation by the covering at night. The experiments of Dr. Wells have shown us that a cambric handkerchief suspended a few inches high by the four corners over a plot of ground will make a difference of four or five degrees of temperature compared with another thermometer not protected, and hence we have the key to the protective influence of the covering of straw. Great Rhubarb growers will now be using straw by the ton, and, dear as it is, they will find their profit in its use. Still the question is worth asking, would not scrim or some other of the many protecting fabrics which are now offered to the public be as good and cheap as straw, while it would certainly be much nearer? A piece of 20 yards might be bought for five shillings—I have had it much cheaper—and this, with proper care, would protect a row or two of early Peas for several years. Apply the same principle to our bush fruit trees and the result would be a crop in seasons when crops fail. Twelve months ago I ran up a temporary glazed shed for the spring protection of bedding and other plants, and not wishing to go to the expense of side walls, had recourse to strong Britannia netting, which was put up at night and taken down again in the day as seemed necessary. After this was used we had on several occasions from 6° to 10° of frost, and yet not a plant sustained the slightest injury. For the summer growth of greenhouse plants, this shed proved the best place

I ever had, for the netting gave sufficient shade to the plants without intercepting the free circulation of air, and the consequence was the plants standing upon the cool ground grew with a luxuriance which I have never seen surpassed and rarely equalled. So convinced am I of the advantages of the plan, that in future I shall arrange my plant houses so that the side lights can be taken away and the netting substituted for the summer and autumn months. For orchard houses I believe this system would be perfection, as it would admit a free circulation of air at all times without a cold draught. In using netting for the fronts of plant houses, there is the advantage that if the atmosphere is very dry and parching, you can, by drawing a syringe-ful or two of water over the netting several times during the day, produce an atmosphere as moist as you please, or as, at any rate, may be needful. This is an immense advantage, and may be secured without any expensive and complicated schemes of ventilation. The means at hand for sheltering crops are numerous, and will readily suggest themselves to thoughtful minds, and with keen parching north-easters upon us, shelter is the thing that we must look to for some weeks to come. P.

### SEED SOWING.

THERE are few subjects upon which more nonsense has been written than about the depth at which seed should be sown. In a work recently published for the special guidance of cottagers they are told to cover the seeds about their own thickness with soil, which would mean that Peas and Beans should be covered one quarter of an inch, and such things as Celery, Onion, or Lettuce, about the thirty-second part of that measure—depths so ridiculously shallow as to show the absurdity of the directions. Soils differ. We have them of all textures, from drifting sand to heavy clay; and to lay down a general rule applicable to all would be impossible. It needs little penetration to perceive that even the smallest seeds may be sown much deeper in light soil than in those of heavy texture. Small seeds, for example, may be covered half an inch deep with light soil, and yet get through; while if covered the same depth with heavy loam the chances are that the seed would perish, more especially should the weather at the time be cold and damp. Good seed secured, the next point, and the greatest element of success, is to have the ground properly prepared to receive it. That can only be accomplished by timely and proper cultivation, or rather preparation of the soil, during the winter season. Light land, so far as its mechanical preparation is concerned, may very readily be brought into condition; but heavy land can only be approached through the agencies of heat and frost. The first dries the clod so thoroughly that when the rain comes and moistens it it falls to pieces like lumps of lime. Frost, on the contrary, rends the clod into innumerable parts, and, after a thaw, that which was stubborn brick earth is reduced to a powder. To keep it so is the next point, and that can only be effected by mixing it with a sandy or other substance, which in future will prevent the adhesion of the parts. This, with proper drainage, will bring the stubborn clays into culturable condition, and so managed they become the most fertile soils in the country. Some years back I had occasion to remodel an old garden, which for thirty years previously had been under the plough. The fruit trees had grown out of all character, some which were dwarfs at the time of planting being bush trees 20 feet high, and nearly double that in diameter. To deal with such a garden required a radical change, and therefore, as the ground had never been drained, that was the first process, to the depth of 4 feet. Then followed a staff of trenchers, who moved the ground to the depth of 3 feet, not necessarily reversing the position of the soil, but throwing the weedy surface soil to the bottom, and bringing a fair portion of strong clay to the surface. This was left in rough lumps, in expectation that the frost would disintegrate it; but, as frost did not come, we had to leave that piece of cultivation to the March winds. These did their work very effectually, so that by the end of the month, after a few hours' rain, the lumps fell to pieces, and, with a careful forking, we were able to bring the soil into fair workable condition. One afternoon in the early

part of April the ground was prepared for Onions, rolled two or three times over with a garden roller, and then drills were drawn preparatory to sowing the following morning. During the night rain came on, so that the next day the soil was in a rather plastic condition; but, as the seed was sown, we had to cover it—a difficult matter. Not, however, to be beaten, we repaired to the rubbish fire, and there procuring some charred earth, mixed it with fresh loam, and, after sifting the two together, covered the seed drills by hand. A few days afterwards, the surface being dry, it was raked over, and then by rolling it with a light wooden roller the work was finished. Onion sowing about the middle of April was of course regarded as a waste of time. The labourers quietly confided to each other the fact that Onions could not be grown in that manner in that locality; and when, as the young plants were peeping through the ground, I gave a fair snow-storm of salt, the crop was pronounced as "finished." Time wore on; the thin green lines gained strength, so that by September a finer crop was never seen, many bulbs being from 12 ozs. to 20 ozs. each, and as firm as need be. Now, in this case the covering of the seed was certainly little less than an inch thick, and if the ground is in proper condition, the soil fine, and the weather favourable, small seeds may be covered that depth; but if it is heavy or plastic, to cover so deeply is almost certain destruction of the seed. In such cases it is always best to cover with fresh soil; and if to it some charred earth, or earth and refuse, can be added, there is a fair chance of benefit arising. For that reason the heavy-land garden should always have a rubbish pile burning, and a fair proportion of the soil ready for use, as it is impossible to have too much of it. Seeds, it should be recollected, cannot vegetate unless the soil be kept in a state of moisture. With shallow sowing the seed is exposed to every change of the weather; to-day it is dry, for a week it may be moist; then we have a few dry, hot days, the sprouting seeds are scorched up, and the seedsman is blamed for supplying a bad article, when in reality the amateur and his teachers ought to be arraigned for their ignorance. With larger seeds, the ground being properly prepared, I always, especially for summer crops, prefer to draw the trenches 4 or 6 inches deep, sowing in the bottom, covering 2 to 3 inches deep, and then earthing the Peas or Beans as they advance in growth with the remaining soil.

Radishes and Lettuces, especially for the summer crop, I generally fork in about 2 inches deep with a five-pronged fork. There are two advantages in this; it cheats the birds, and at the same time gives the seed a chance of vegetating strongly. For complete success, especially for the cultivation of leguminous crops through the hot weather, there is no plan so good as to take out trenches, say 18 inches deep and as much wide, placing 6 inches of good rotten dung in the bottom, and nearly as much soil, upon which the Peas or Beans may be sown. Crops so sown get a root-hold of the soil which is impossible under the surface system of cultivation, and it is not too much to say that one row of Peas or runner Beans so grown, with ample room for the sun to act on both sides, will yield more produce than three rows of the same length grown on the ordinary plan. Crops so grown should have plenty of room—indeed Peas, according to their height, should have from 8 to 12 or 15 feet between the rows—and then the produce will not only be greater in quantity, but of very superior quality, while the space between the rows will be suitable for dwarf-growing crops. Crowding is one of the sins of the small gardener; because he is pinched for space, he must crowd his plants, forgetting that every living thing must have room to grow, and if it has not, attenuation must be the consequence. Of this there can be no doubt, and yet so covetous are many, that a man with a few score plants more than he has room for would rather spoil the lot than give or throw them away. With good seed thick seeding is waste, and the neglect of timely thinning must result in the injury of the crop. Where there is time, as is generally the case with amateurs, it is a capital practice to drop the seed of Onions, Carrots, and the like at those distances apart which they require for full growth. Three or four seeds in each patch will be quite sufficient, and, as the distance admits of thorough cultivation around the plants, superior growth is the consequence. This is something like

dibbling the corn crops, a pint or two of seed upon properly prepared ground producing as great a return as when two or more bushels are sown. With scarce or expensive seeds dibbling is a decided advantage.

D. T.

#### MATERIALS FOR BOTTOM HEAT.

THE use of fermenting material for growing the more tender kinds of plants is a practice old as the art of gardening itself, and the expedients resorted to to get a little "bottom heat" are numerous, and some of them very skilful. The most primitive is that of taking advantage of solar heat, and digging it in. Thus in the open garden, if we mark out a plot of ground, and daily, just as the sun is leaving it, dig it over and make the surface fine, we shall in the course of a week or ten days, according to the power of the sun, raise the temperature of the soil 5° to 10°; the meaning of the action being that we dig the heat absorbed by the surface soil in, instead of allowing it to be radiated into space, as it would be if left exposed upon the surface. Thus the daily digging of a piece of ground is of much greater importance than the early planting of the crop, inasmuch as in one case you secure the bottom heat before planting, while in the other you have to wait for the warm rains of spring to carry the life-invigorating heat to the roots of the plants. Practically considered, you may warm the ground before sowing or planting by this simple process, but you must rake the surface fine so as to prevent the heat from escaping between the interstices of the soil, and if you supplement that raking by covering with a mat or carpet from sunset to sunrise, you will prevent radiation and attain your object in a shorter time. The dung bed for Cucumbers and Melons, the ridge of leaves, dung, and vegetable refuse for early vegetables, are among the oldest of gardening expedients for obtaining bottom heat, and there are other things which we may examine *seriatim*. But of all things for bottom heat "sweet" stable manure is the best, because the results of its fermentation and decomposition are beneficial to the life and substance of the plants which you wish to assist. You may by fire either applied to water or to flues command the same amount of heat; you may also saturate the atmosphere with moisture, but you cannot command that combination of plant stimulants which results from the decomposition of fermenting matter, such as stable manure. Hence, many of our best gardeners look to the hot-bed for growing certain plants, and especially for propagating, and I could enumerate many rare and beautiful stove plants that may be grown vigorously upon dung heat which cannot be secured under any other circumstances. Still the labour attending fire heat is much less than that from dung, and hence the reason why fermenting material has been superseded by hot water and the primitive flue. But with all our modern command of fire heat, the skilful cultivator still resorts to fermenting material. If he has pipes or flues he covers them with dung, or leaves or tan, or like our friend Mr. Westland, when at Lord Belper's, he may take "bobbin chips" and get bottom heat from them. Other gardeners also have followed his example with good results. But be it recollected that the chips must be from native timber, Sycamore, Horse Chestnut, Beech, and other soft woods, and that if the chips are made while the wood is yet green the chances of their fermenting when brought into a mass are more certain, but if they are dry they must be moistened, mixed, and packed in a heap until fermentation commences. These chips do not encourage worms or other insects, and are found much more durable than tan or straw. Be careful, however, to avoid chips made from foreign timber, as the decomposition is slow and the heat irregular. Bobbin chips can, of course, be obtained where "life among the spindles" is a leading occupation, and hence Manchester, Nottingham, and Derby, may be considered the centres of such work, and there chips may be procured at a reasonable price. The London market gardeners use spent Hops from the breweries extensively for bottom heat, for growing various kinds of vegetables and saladings in frames, and some of the market growers of Roses for Covent Garden also use them very extensively in their forcing houses as a substitute for tan. To see at this time of the year from ten to twenty thousands of fancy Roses in one garden growing upon fermenting beds of spent Hops is not an uncommon sight, and I am told, but have no experience in the matter, that Hops, when decomposed, make capital material in which to grow soft-wooded plants. Hence the Hops of large breweries are worth procuring; indeed, market gardeners are so alive to this fact that they furnish themselves with this material according to convenience and the extent of their ground. Not only do they use spent Hops for bottom heat, but to assist in the accumulation of the ordinary manure heap. Spent Hops form an excellent sponge for absorbing liquid manure; they are, therefore, sometimes steeped in it, and afterwards transferred to the land.—W. M.

**Conover's Colossal Asparagus.**—This fine variety has been sent out by us during these last three years, being originally received from a first class house in America, after testing it with the reputed best kinds, and having proved it to be superior to all others known to them. Its most excellent and superior character has now been proved not only in English gardens, by its annual demand in preference to others, but its superiority abroad has also been proved. We are in receipt of a communication from Dr. Cornish, of Madras, whose success in the cultivation of this variety has so far exceeded the results of his experience with others previously grown by him under similar treatment, that he was requested by the Committee of the Agri-Horticultural Society of Madras to draw up a paper detailing the results of his experience, and it is from this communication we learn that, allowing for the rapidity of growth common to all vegetables in that climate, from the seed of this Asparagus, which was received from us in November, and sown on the 28th of the same month, with the usual treatment, the bed commenced yielding a crop of shoots fit for the table in July, such as would do credit to Covent Garden, a continuous stated cutting being made from the bed whilst in season, thus showing that the bed commenced yielding freely within seven months. Dr. Cornish further states, that "though the upward growth of Asparagus is so rapid in this climate, yet, in comparison with the thin and slender crowns obtained from other kinds, the 'Colossal' variety comes up with a good sturdy head, or crown, and in justice, I may state that this is the finest variety of Asparagus I have yet seen for size, strength, delicacy of flavour, and tenderness."—*E. G. Henderson's Catalogue.*

#### NOTES AND QUESTIONS ON THE KITCHEN GARDEN.

**Snow's Winter White Broccoli.**—I don't know any vegetable at this season so acceptable as this Broccoli, when true. I am this season growing three packets of seeds, obtained from as many different seedsmen. No. 1, sown in March, is now coming in, but the heads are green and frothy. No. 2, sown same time, is about 4 feet high, and worthless. No. 3 is short and stocky, just in now, January 14, and the heads are perfectly protected by their own leaves, white as snow, firm as it is possible for a Broccoli to be, and the stock is true.—*R. GILBERT, Burghley, Stamford.*

**Liquorice.**—Kindly tell me if it is practicable to grow Liquorice in this country. W. W. Liquorice is seldom grown in gardens; but it is extensively cultivated in some parts of England, especially in the neighbourhood of Mitcham, in Surrey. A deep, rich sandy loam suits it admirably. Crops preceding the Liquorice should be heavily manured, but not the Liquorice, which, like most other root crops, dislikes fresh manure. If the ground is really poor, it may be applied; but in that case it should be trenched deeply into the soil. Trench the ground to be planted, casting it up into rough ridges in autumn; level these down in the end of February, and plant, in rows 3 inches deep and 3 feet apart, finger-length cuttings of the underground stems of the plants, about 18 inches asunder in the rows. Three years will elapse before the roots or rather creeping stems are ready for use, they should then be taken up and stored like other root crops.]

A LITTLE flower so lowly grew,  
So lonely was it left,  
That Heaven looked like an eye of blue,  
Down in its rocky cleft.

What could the little flower do  
In such a darksome place,  
But try to reach that eye of blue,  
And climb to kiss Heaven's face?

And there's no life so lone and low  
But strength may still be given,  
From narrowest lot on earth to grow  
The straighter up to Heaven.

—*Gerald Massey.*

**Do Plants throw off Carbonic Acid Gas?**—Plants have commonly been thought to differ from animals in the gases which they secrete; the animal parting with carbonic acid, while the plant gave out oxygen. Dr. J. C. Draper, of New York, however, maintains that all living things, whether animal or plant, absorb oxygen and give out carbonic acid; and that the life of the plant is one continuous drinking-in of oxygen gas. Having grown plants similarly nourished in the dark and in sunlight, he found that all the same parts were produced in both cases almost at the same times, and that the slightly slower evolution of the series grown in the dark is marked by a slightly smaller weight, while the same plant measured by night and by day grows slightly faster in darkness than in sunlight. The roots of plants grown under both circumstances throw out the same kind of excrement. Therefore, as the evolution and weight and root-secretion agree, he urges that the carbonic acid has been, in both cases, thrown off as a consequence of growth, and has never been absorbed by the roots, and then given out as vapour from the leaves.

## THE ARBORETUM.

### THE BANYAN TREE.

Among the many striking features of tropical vegetation none are more interesting than the Fig family, which has from early history been mentioned in connection with religious and secular usages. The produce of the India-rubber tree (*Ficus elastica*) is too well known to require comment. The great Banyan tree of India (*Ficus indica*) is so gigantic and determined in its growth as frequently to cover from its starting-point of a solitary plant whole acres of land, beating back and overpowering its less energetic associates. The accompanying sketch shows a group of the Banyan tree which has covered from one patriarchal stem several acres by the simple process of throwing out from the arms of its extended branches roots, which gradually but surely find their way to the earth, and firmly attach themselves to their natural element, forming auxiliary stems, props, and guy lines, to keep the ponderous head of the parent tree in position; without such aids, the heavy load of bright dark green and leathery foliage would inevitably crush to the ground the elder plant. I have never yet met with an uninteresting species of *Ficus*, from the small Ivy-like *F. repens* to the fruiting Fig so well

had evidently covered a wide-spread area of land, but as civilization had grown in its vicinity, it had been cut back for the merchant residences and villages that form this West-end portion of Colombo. This patriarch stood on the border of the Government road from Colombo to Point de Galle, was upwards of 30 feet in circumference at its base, and was supported by a few air-root stems upwards of 60 feet in height. It had, no doubt, witnessed the decades of the Portuguese and Dutch Governments in that island, but in the winter of 1867, during a heavy gale of the north-east monsoon, it came down, fortunately doing no greater damage than knocking down the portico of Banyan Tree House, where I was then staying, upsetting about a hundred Cocoa-nut trees in its fall, and blocking up the mail road to Galle for about ten days; although Major Skinner, or one of his assistants, had a good portion of the pioneer division employed in clearing away the *débris*.

PETER WALLACE.

### THE MOVEMENT OF THE SAP.

The movements of water in plants are quite incorrectly stated in all our English text-books, and for the best information on the subject I would refer you to "Sachs's Lehrbuch der

A spreading Fig Tree in Ceylon.

known in horticulture and commerce: the Sycamore Fig forms the avenue from Cairo to Shubra (Mehemid Ali's princely garden in Egypt). The India-rubber Fig, too, so well known in its dwarfer state as one of the best additions to our subtropical gardens, is familiar to every lounge in Hyde Park and Rotten Row. The sacred tree of Buddha (*Ficus religiosa*) is found in the vicinity of every Buddhist temple in Ceylon and India, and the big-leaved Figs *Neumanniana*, *Aizeli*, *nymphaeifolia*, and others that were introduced into the jungle of the conservatory at Chatsworth under the genius of Paxton, aided by the intelligent and liberal patronage of one of the most unassuming, but noblest of men, viz., the late Duke of Devonshire. All these Figs and a score of others have their special interest. But to the Banyan tree must be given the palm of praise, not only for its gigantic growth, but for its truly noble and picturesque appearance in the landscape, and also for its intense verdure, which neither tropical sun nor droughts appear to disturb. At a distance of several miles it may be readily distinguished from its associates, by the density of its colour and foliage. An almost historical Banyan grew near Colombo, in Ceylon, at Colpetty, giving the names of Banyan House, Banyan Villa, &c., to most of the residences in its neighbourhood. This tree

Botanik," third edition, page 581, *et seq.* Two distinct currents of water (*i. e.*, sap, or water with certain substances in suspension or solution) occur in plants—a slow and a rapid. The rapid current is exclusively related to the process of *transpiration*. It, therefore, varies with the season and time of day. The other—slow movement—is connected with the transport of assimilated matters (as starch) from one part of the plant to another, as from assimilating organs (chiefly foliage leaves) to reservoirs of nutrient materials, or to the growing points of stems and roots, or wherever cell-multiplication or cell-enlargement is going on. The rapid current takes place in the daytime, during sunlight, and the fluid passes up in the walls of the wood-cells of the *fibro-vascular bundles*. The researches of Naegeli clearly prove this, although all our English books say it is through the cavities of the tubes, *not* in the walls. The rapidity of the current, as calculated by Sachs, was 23 ctns. per hour in Silver Poplar. I observed a rate of from 42 to 46 ctns. per hour. In mentioning my experiments, Sachs says that the amount is probably *too small*. In this I agree, because my experiments were made in the beginning of October. If they had been done in *June*, the results obtained would probably have been *double*. The slow current is quite irregular, and may move in

any direction. Wherever assimilated materials are wanted, the fluid will move in that direction, up or down. It depends on osmose chiefly, and is a true movement from cell to cell, not like the rapid movement through the actual substance of the walls. In the Cherry Laurel, the total water present is 63 per cent. Of that I calculate that 6 or 7 per cent. only is water of transpiration, and in rapid movement, while 56 to 57 is in slow movement. No other experiments on this head have been made, and, as it is a matter of great importance, it ought to be fully investigated.

W. R. McNAB.

Royal College of Science, Dublin.

### THUJA GIGANTEA AND LIBOCEDRUS DECURRENS.

THE tree which is commonly known in Vancouver Island, British Columbia, Washington Territory, and the northern portion of Oregon as "the Cedar," is *Thuja gigantea* of Nuttall ("Rocky Mountain Plants," p. 52, and Smith's edition of Nuttall's "Silva," p. 102). The "Pencil Cedar" of the same region is a species of *Juniperus* allied to, but distinct from, *J. virginiana*, which I first described under the name of *J. Henryana*, in honour of one of the first of Scottish amateur horticulturists—Mr. I. Anderson-Henry, of Wood-end. In California *Thuja gigantea* is also called "the Cedar," but to distinguish it from *Libocedrus decurrens*, Torr., which is sometimes found in company with it, and is called "The Red Cedar," it is known in that State, curiously enough, as "the White Cedar." Parlatore's synonymy is here, as in most cases, quite correct. *Libocedrus decurrens*, as will at once be seen by any one who will take the trouble to glance at Torrey's excellent figure in his "Plantae Fremontanae" ("Smithsonian Contributions to Knowledge," vol. vi., pp. 7, 8, pl. iii.), is entirely different from *Thuja gigantea*, with which Mr. Gordon has strangely confounded it in his "Pinetum," p. 105, and supplement, p. 102. It is also the *Thuja Craigana* of the Oregon Committee (or rather, of Professor Balfour, who published in a private brochure a very good figure of the tree). The error of confounding it with *T. gigantea* I pointed out in one of my published letters to Mr. Anderson-Henry long before Parlatore did, and have since, in various publications in the English and German languages, kept it up. *Thuja Menziesii* is only a synonym of *T. gigantea*, being so named by Douglas in ignorance of the prior publication of Nuttall, but afterwards he withdrew the name. *T. Lobbii* is also the same species, or at best only a very slight variety. Now, as regards their distribution, *T. gigantea* is very common in Vancouver Island, British Columbia, Washington Territory, and Northern Oregon to the west of the Cascade range of mountains. To the southward it is far from common, and in California is a rare tree; while to the east of the Cascade range it is only occasionally met with (generally in a scrubby form) in the damp dells and river bottoms, but far departed from its pristine glory on the banks of the Lower Columbia or Fraser Rivers. It is not found at any considerable height on the Pacific seaboard; but on the Cascade Mountains, and towards the Rocky Mountains, it rises to a good elevation, being found in Utah at a great altitude on that range. *Libocedrus decurrens* has, on the other hand, a geographical range from about 44° to at least 33° N.E. and westward to the Sierras and Cascade Mountains. It does not seem to go further east than these mountains. The tree is found at an elevation of from 4,000 to 5,000 feet in the Sierra Nevada in California; but further northwards in Oregon it grows at a much lower elevation, as mentioned in my letter, quoted by your correspondent. I did not find the tree north of Eugene, in Oregon (latitude 44° 2' 14" North), and during my journey across the Cascades, a little southward of this point, I found it abundant here and there in the valleys, but very scarce on the eastern side of the mountains. Again, in the Rogue River Valley I saw a few trees, and one or two in Josephine county, near Kerbyville, and southward, in the Siskiyou Mountains, it is quite common. Nowhere, when I saw it, did I see any *Thuja gigantea*, and, as I have already remarked, *T. gigantea* is a rare tree where this is common, or, indeed, begins to appear; and further north, in Northern Oregon, Washington Territory, Vancouver Island, and British Columbia, *Libocedrus* is as unknown as in England. The names of trees given by tourists or travellers in the North-west are as little to be depended on as these usually are in most countries. Indeed, I know no book on the region in question where the names of the trees are correctly given, and in one or two the ignorance displayed is almost miraculous—almost as much so as the ridiculous errors in locality circulated by the labels attached to most *Coniferae* grown in Pineta in this country. North-west America is an immense region, possessing all climates. Lower California is almost tropical, while in Upper California there is perpetual snow. The coast climate of British Columbia is mild, that of the interior

very cold in winter; the coast climate, however, varies much, according to latitude, &c. Finally, I ought to mention that the name White Cedar is sometimes applied in Oregon to Kellogg's *Cupressus fragrans*, which is, however, generally known by the names of Ginger Pine, Port Orford Cedar, or by the more indefinite one of Oregon Cedar. *Thuja borealis*, Fischer (*Chamaecyparis nuntkaensis* of Spach, *Cupressus nutkaensis* of Lambert), is also known on the north-west coast by the name of the Yellow Cedar or Yellow Cypress. It is, however, a much less common tree than any of the others named.

I have given a very full history of these trees in my "Monograph of the Coniferous genus *Thuja*, Linn., and of the North American species of the genus *Libocedrus*, Endl." (Trans. Bot. Soc. Edinburgh, vol. ix., part 2). However, in case your correspondent is not able to see it, would you allow me to append to this already too lengthy memorandum the following synonymy of *Thuja gigantea* and *Libocedrus decurrens*:—

*Thuja gigantea*, Nuttall (*l. c.*); Gardeners' Monthly Hort. Advertiser (Philadelphia), June, 1859 (good figures); Spach, Hist. Veg. Phan. xi., p. 342 (Encl. Syn. Dougl.); Endl. Syn. Conif., p. 52; Lindl. and Gordon, Journ. Hort. Soc. v., p. 206; Cooper, Nat. Hist. Wash. Terr., p. 21, and p. 265; Newberry, Trees of Oregon, in P. R. Survey, vi. (Williamson's Report), pp. 56, 57 (fig. 22,—good); Lyall, Journ. Linn. Soc. vii., p. 144; Hook. Fl. Bor. Am. ii., p. 165; Carrière, Traité (*partim*), p. 105, &c.—*Thuja Menziesii*, Dougl. MS.; Carrière (*partim*), p. 106; Gordon's Pinetum, p. 323.—*T. Lobbii*, Hort. "T. Craigana et *T. gigantea*," R. Br. (Campst.), (*pide* Gordon et Carrière, 1863—1865; *postea* "T. gigantea" *olim* T. Nuttalliana, "Dougl." (*teste* Gordon, Supp., p. 102). ? *Abies microphylla*, Rafinesque, Atlantic Journal, p. 119.

*Natural varieties*.—(a) var. *plicata*.—*Thuja plicata*, Don, Hort. Cantab., ed. 6, p. 249, &c.; *Thuja occidentalis plicata*, Lond. Encyc., Trees, p. 1110, f. 2108; *Thuja Warreana*, Borth. Cat., 1837. The *T. plicata* variegata, var. *panachée* of M. Carrière, is a sub-variety which has sported in cultivation. (b) var. *microcarpa*, R. Br. (Campst.); *Thuja nova* species, No. 273, R. Br. (Campst.) in "Farmer," May 16, 1868.

*Libocedrus decurrens*, Torr. in "Plantae Fremontanae" (*l. c.*), Philadelphia Monthly Hort. Advertiser (*l. c.*), figure good; &c.—*Thuja Craigana* Greg. Comm. (Balf.) in "Description of Coniferae Collected by Mr. Jeffrey," (private distrib.), plate (good); Lindley in Gard. Chron. 1854, p. 53; *Libocedrus Craigana*, Hort.; *Libocedrus gigantea*, Hort.; *L. glauca* Hort. (Laws.)? *Thuja gigantea*, Carr. *l. c.*, p. 105 (*partim*); Gordon, *l. c.*, p. 321, et Supp. 102 (*partim*). *Cupressus*, No. 750, Jeffrey's MS.

Of the latter there are no natural varieties, so far as I am aware. I have seen two cultivated ones, "*T. gigantea* divaricata" and "*T. gigantea* glauca," but they do not require notice.—R. Brown, in *Gardeners' Chronicle*.

[The above interesting letter clears away the confusion that has existed between two of our noblest trees, one of which, *T. gigantea*, has, we are satisfied, suffered much from not being known by its right name.]

### NOTES AND QUESTIONS ON TREES AND SHRUBS.

**Large Oriental Plane.**—A noble specimen of this Plane—dense, spreading, and well-shaped—is growing in the garden belonging to Emmanuel College, Cambridge. It is 75 yards in circumference, the bole being 11 feet round at the ground, and of about equal thickness to the branches. There is also in this garden a remarkably fine English Elm.—J. J. CHATER.

**Large Western Plane.**—In the Fellows' garden at Sidney College, Cambridge, is a noble specimen of *Platanus occidentalis*. At 12 feet from the ground the trunk is divided into two huge limbs, and at a foot from the ground the diameter of the bole is 5 feet. In this garden are also two fine Chestnuts, a good specimen of *Ailantus*, and until recently two spreading specimens of *Cornus mascula*, which, to make way for alterations, have unfortunately been mutilated.—J. J. CHATER.

**Large Mistletoe Plants.**—The parish of Curland in this county (Somerset) abounds in Mistletoe, and some branches I have had been so large that it may be worth while to notice them. At Christmas, 1870, I got a bough weighing 26 lbs., full of berries. At Christmas, 1871, I got two, one weighing 19 lbs., without berries, the other 8 lbs., with a great many berries. This last Christmas I again got two specimens, one weighing 8 lbs., the other 7 lbs., both covered with berries. Are not these, especially the first, unusually large? It looked like a tree hung up in my small dining-room.—C.

**The Ailantus as a Street Tree.**—There is a good reason why the *Ailantus* should not be planted on the roadside for shade, that is, so exceedingly disagreeable is the odour of the young wood and flowers of this tree, that while it is in blossom, the atmosphere for a long distance from the tree is filled with this intensely sickening odour. That it grows rapidly while the tree is young, there is no doubt, and this is its only redeeming quality. It thrives in poor soil, and for getting a rapid growth in five or six years on this character of soil, where no one can be annoyed by its odour, the *Ailantus* will be found to be one of the best trees to plant.—*New York Tribune*.

**Names of Cupresses.**—Kindly tell me who Mr. Corney and Mr. Gouwe were, after whom *Cupressus Corneyana*, and *C. Gouveniana* were named, and oblige. ALPH. [Cupressus Gouveniana was so named by me in the Journal of the Royal Horticultural Society in 1848, in compliment to James Robert Gouwe, Esq., the originator of many fine hardy hybrid *Rhododendrons* and *Azaleas*, at the Earl of Carnarvon's, at Highclere. *Cupressus Corneyana* was so named by Mr. Joseph Knight, of the Exotic Nursery, Chelsea, in 1850, after Mr. J. Corney, a China merchant, who brought it and several other plants from China, and disposed of them to Mr. Knight. It is the true weeping Cypress of China.—GEORGE GORDON.]

## CLIMATE AND VEGETATION.

BY ALEXANDER BUCHAN, M.A.

METEOROLOGY is a branch of knowledge which, if not so closely allied in the order of the sciences to botany as is zoology, is yet beyond all question the science that deals with those influences and conditions which most powerfully affect vegetable life. It is thus the science which is practically linked the closest with botany. I therefore propose, on the present occasion, to make some remarks on climate and weather, relative to the geographical distribution of plants; and I am the more induced to do so, having completed certain inquiries regarding prevailing winds and rainfall, which are so intimately connected with this subject. In a singularly lucid paper, read before the Academy of Sciences of Paris in December 1817, Decandolle endeavoured to trace the causes which limit vegetable species towards the north, in Europe, and similar regions. As respects temperature in its relation to this limit of the distribution of plants, the result he arrived at was, that "every species, having its northern limit in central or northern Europe, advances as far as it finds a certain fixed amount of heat, calculated from that day of the year when a certain mean temperature commences to the day when that mean temperature terminates." This law is applied with great ingenuity in explanation of the northern limit of *Alyssum calycinum*, *Eranium europæus*, and *Dianthus Carthusianorum*; and without doubt, the method of expressing by an arithmetical formula the limits of species may well be regarded as forming an epoch in geographical botany, inasmuch as it points out how this great department of natural science may be placed on a strictly scientific basis. The operation of this law can be best investigated with reference to Wheat, the Vine, the Sugar-cane, the Tea-plant, and other cultivated species; for the obvious reason, that being as far as possible protected by man, they have the limits of their distribution determined almost exclusively by climatic conditions.

Boussingault examined the distribution of Wheat on the continent of Europe, and arrived at the conclusion that it required 8218° F. from the time it begins to grow in spring for the proper ripening of the seed; and, moreover, that this heat must be partitioned so as to secure a mean summer temperature of 58° during the development and maturing of the seed. This minimum amount of heat required for the maturing of their seeds is a vital consideration. We have proved in Scotland that a mean temperature of 56° during this critical period, with the average sunshine and rainfall of the Scottish summer, is sufficient to ripen Wheat properly. Not only so, but it was found that the Wheat crop of 1864 ripened well with only an average temperature of 54.4°. In that year, however, the sunshine was much above the average, and the mean of the daily maximum temperature was high—being as high as in August 1861, when the mean temperature was 57.4°. It is probable that the longer time the sun is above the horizon in Scotland, as compared with Germany and France, renders the ripening of this cereal possible with a lower mean temperature; and when this is combined with a clear dry atmosphere, and consequently a blazing scorching sunshine, grain of excellent quality is ripened, though this mean temperature rise no higher than 54.4°. From this it is clear, that in regarding the influence of temperature on the bringing of plants to maturity, it is not mean temperature merely, but the way in which this vital element is distributed through the day and the night, particularly at the critical periods of the plant's growth, which must be considered. A high mean temperature, with little variation, implies a comparatively low day temperature; and, on the other hand, a moderately low mean temperature, with a large daily range, implies a high day temperature; so that a climate with a comparatively low mean temperature may yet afford the warmth required in carrying on the higher functions of the plant, which another climate of a higher mean temperature could not supply.

Now, that which in the highest degree determines the mode in which temperature is partitioned throughout the twenty-four hours of the day is the amount of cloud and the degree of moisture in the atmosphere, to a knowledge of which we must look to the rainfall through the months of the year as furnishing the best available key. The rainfall affects plants directly through the nourishment it conveys to them, and indirectly through the state of the sky, which its amount or absence implies. Indeed, so great is the influence of the rainfall on vegetation, that we cannot be far wrong in supposing it to be co-ordinate with that of temperature. Whatever the law may be which expresses the atmospheric conditions that determine the limits of the growth of species, it must include in its function both the heat and the moisture of the air. Decandolle deduced the law from the distribution of species over a region whose climates are marked off from each other rather by variations of temperature than of moisture. He then endeavoured to extend it so as to account for the distribution of the Flora of other regions, the climates of which may be characterised either as moist at all seasons, or subject

to marked variations of moisture at stated seasons. Perhaps not the least valuable of the results arrived at by him is the negative one stated in these words:—"On the borders of the Mediterranean Sea, the limits appeared so often determined by the humidity, or by causes still unknown, that the operations of temperature always escaped my calculations."

It may be predicted that when the limits of species have been drawn with some exactness for Central and Northern Europe, the region from which Decandolle took his examples, they will be found to coincide with no mere temperature lines, however calculated and determined; inasmuch as there are much greater differences in the climates of this region than are generally supposed, as regards the rainfall, particularly in the manner of its distribution over the year. Thus, to take one point only, the time of the annual maximum rainfall occurs over a large portion of France and neighbouring regions in May; in the south of Austria, south of Prussia, and south of Russia, in June; in Germany and centre of Russia, in July; and in the north of Russia, in Sweden, Denmark, Holland, and Belgium, in August—differences which cannot fail to have an important bearing on many vegetable functions, and consequently on the area of distribution of many species over these regions. As regards perennial species, especially trees and shrubs, the limit of their distribution is in many cases determined by the absolutely lowest temperatures that occur. In connection with this point, the great frost of Christmas 1860 gave very striking illustration. These minimum temperatures are no doubt in a great measure due to the latitude, but they are more particularly brought about by the state of the sky, and they occur in greatest intensity in certain situations. If the climate be characterised by a dry calm atmosphere and clear skies, the loss of heat by terrestrial radiation during the nights in winter is rapid and great, and the temperature of the air falls correspondingly low. Owing to the greater density, and consequently greater weight of the layer of colder air in contact with the ground, currents of air set in down the slopes of the country whose surface is being cooled, much in the same way as water, and settles in the low-lying situations. And it is well known that it is just in such situations where the destructive effects of frost are greatest on trees and shrubs.

The influence of temperature on the distribution of plants is twofold:—1. A temperature ranging between certain limits is required for the proper development of each species, especially for the maturing of its seed; if the mean temperature falls below this, a condition vital to the propagation of the species is wanting, and if it rises above it an injurious influence is brought to bear on the well-being of the plant. 2. If the temperature falls below a certain point, which point probably differs with each species, the plant is killed, either by the freezing of its juices, and the consequent rupture of its tissues, or in some other way not yet understood. Occasional high temperatures are less injurious, because they only temporarily affect the welfare, instead of proving destructive to the life of the individual. The relation of moisture to plants is analogous to that of temperature. A certain amount is required, whether supplied in the form of rain or dew, or abstracted from the invisible vapours of the air by the plant itself, between the limits of which the plant will live and thrive. If the supply falls below the limit, or rises above it, the vital functions are interfered with, and so far as the species is concerned, the conditions of its existence are there wanting. Now, what we wish to direct special attention to is this: Of these two conditions—heat and moisture—we have presented to us in the distribution of rain a body of facts which leads, where intelligently interpreted, to a knowledge of the laws which determine the distribution of plants more quickly and certainly than in the facts of the distribution of temperature. It is not merely the knowledge respecting the daily and annual fluctuations of the temperature of a country which may be inferred from its rainfall; it is not merely the more important consequences which immediately result to the plants from a change in the humidity of the climate, than from a corresponding change in its temperature; but what particularly concerns the distribution of plants is this vital distinction between temperature and rainfall, as regards their geographical distribution, viz., climates merge into each other, as respects temperature, by comparatively nice gradations; whereas the most diverse climates, as regards moisture or dryness, are frequently quite contiguous to each other, being placed, as it were, sharply side by side.

It is to the prevailing winds we must look for an explanation of the rainfall, and the broad principles of the connection are these:—1. When the prevailing wind has previously traversed a large extent of ocean, the rainfall is moderately large. 2. If the winds are at the same time advancing into colder regions, the rainfall is largely increased; and if a range of mountains lie across their onward path, the rainfall is also thereby largely increased on the side facing the prevailing winds, and reduced over the regions lying on the other side. 3. If the winds, though arriving from the ocean, have traversed

a considerable extent of it, the rainfall is not large. 4. If the winds, even though having traversed a considerable part of the ocean, yet on arriving at the land proceed into lower latitudes, or regions markedly warmer, the rainfall is small or nil.

(To be continued.)

## THE GARDEN IN THE HOUSE.

### CROTON UNDULATUM.

Of the many species of Croton under cultivation this may be safely regarded as one of the best. It is a native of the South Sea Islands, whence it was introduced by the late Mr. J. Gould Veitch. The petioles of the leaves are an inch or an inch and a half in length, thickened and green at both extremities, and purplish in the centre; the leaf blade is from 7 to 9 inches long, and 2 inches wide, oblong-acuminate, tapering at both ends, and the margins are beautifully undulated or waved. Mature leaves have a dark metallic green ground, beautifully spotted with irregular blotches of crimson, which are visible on the under side, but much paler than on the upper surface. The midrib and veins on the upper side are of a purple colour, and green on the under side. Young leaves are green, blotched with yellow, but, as maturity approaches, the green becomes darker, and the yellow changes to crimson. The plant itself is compact yet graceful in habit, and forms a pretty ornament for a dinner table. Mr. Ward, gardener to F. G. Wilkins, Esq., Leyton, got a plant of this Croton last winter, nicely rooted in a small pot from which he shifted it on into larger ones as required. He kept it near the glass in a moist stove, and gave it a little bottom heat. The compost used for it was two parts loam and one of peat with an ordinary admixture of silver-sand. This plant is now eighteen months old from the cutting, and has made during the past summer five shoots, four of which measure individually nearly 4 feet in length. Indeed, since last year its growth more resembles that of a vigorous growing, broad-leaved Willow than that of one of our most interesting ornamental tropical plants. The foliage is marvellously rich and brilliant, and the young wood well

ripened. Before the end of another twelve months, therefore, this plant will be ready to take its place amongst a collection of large specimens of fine foliaged stove plants at our exhibitions. When used for the decoration of the dinner table, it is not advisable to encourage bushy growth. W. F.

### SIZES OF VASES FOR TABLE DECORATION.

I SHOULD feel extremely obliged to "W. T. P." if he would give his opinion upon the following questions relating to table decorations. Supposing three epergues, with trumpets, are used for a table 12 feet by 6 feet, what height should they be? Should the centre one be the highest, and, if so, how much higher than the two end ones? Should there be other stands of flowers in or about the centre, and if so, how high? Also, how high should the small glasses be around the sides of the vase, and how many of them would be required for a table the size I have named? and what is the best shape for the purpose?

T. W.

[I have much pleasure in replying to the enquiries of "T. W.," who, I have ascertained, when using the word "epergne," means what is commonly known as a "March stand," that is, a straight stem of glass standing in a flat dish and supporting another flat dish on its top. This March stand, with a trumpet-shaped vase in the top dish, is the form of receptacle for flowers, of which "T. W." proposes to place three upon a dinner-table 12 feet long by 6 feet wide. The central one should be of the following proportions:—Lower dish 12 inches diameter and 2 inches deep; upper dish 6 to 9 inches diameter, and 2 inches deep; length of stem not less than 22 inches; height of trumpet-vase 10 inches or more. The two other stands should be alike, but the proportions should be as follows:—Dishes, same as for the central stand, or rather smaller; length of stem not more than 8 inches; height of trumpet-vase not less than 14 inches, and very slender. If "T. W." will get stands made of these dimensions, he will find that flowers will look well in them, and, when arranged, will not intercept the view across the table. The centre of each end-stand should be placed 2 feet 9 inches from the centre of the middle stand. If the lower dishes of these three stands are fringed with long handsome Fern fronds, it would not be advisable to put on the table any other stands or vases of flowers, excepting a coat-flower in front of every gentleman and a dress bouquet in front of every lady; and these should

*Croton undulatum.*

be in small trumpet-vases from 4 to 6 inches high ; but if the lower dishes are sparingly decorated, there will be room for four vases, to be placed about 21 inches from the centre of the table, and about the same distance from the sides. These four may be of any form, provided that they are not more than 9 inches high. The shape that I should generally use for such a purpose would be a trumpet-vase, either standing on a small foot or standing in a dish about 6 or 7 inches diameter ; but much would depend upon the character of the flowers which I had to put in them.—W. T. P.]

### THE ROMAN MARSH LANDS.

I AM quite convinced that malaria arises from stagnant waters, either on the surface of the soil or at little depth. I also grant that the presence of decomposing vegetable matter is necessary to develop it. I also believe that when a sheet of water is of sufficient depth it is no longer noxious. A commission, of which I am a member, is now studying the plans for draining the marshes of Ostia and of Maccarese, at the mouth of the Tiber. It is proposed to exhaust them by steam-power, which we consider the cheapest and quickest process possible. Of course, a like result for purifying the air might be obtained by deepening the waters to a minimum of one metre (40 inches). I say one metre, because in our climate less would be insufficient, and even with that aquatic plants of rapid growth would require constant clipping. When I add, that at present the greatest depth in the marshes of Ostia is only 31 inches, and the surface to be drained is over 5,000 acres, while for Maccarese only a few hectares are more than one metre deep on a surface of 10,000 acres, it is obvious that the expense of deepening would be enormous, even admitting that the dredgings from one spot should be conveyed to fill up another. It had also been proposed to "warp" the lower parts with the deposits of loam from the Tiber, and thus attain a sufficient slope for the waters to run off. But, apart from the difficulty of bringing turbid waters to the marshes, with the limited fall of the Tiber between Rome and the sea, it has been calculated that the time necessary would be over 50 years, and thus only future generations could be benefited. Then, it had been suggested to raise the surface soil by bringing down earth from the neighbouring hills. That would be practicable, and require only a limited time, but the conveyance of 30 millions of cubic metres of earth over a mean distance of  $2\frac{1}{2}$  miles would cost £1,800,000 sterling for the improvement of only a portion of the Agro Romano. It is therefore determined to surround the marshes by a circuit of deep trenches, conducting to the Tiber and to the Arone the upland drainage, while the marshes, of which the bottom in many points is below the level of the sea, shall be drained by steam-engines, as has been practised in Holland and also in Italy, where over 80,000 acres of land in Polesina and the Veronese formerly submerged are now reclaimed. Here, we all know, that when a marsh is drained either by trenching or by pumping the first year, and even the second, malaria augments and subsequently disappears only gradually by cultivation and deep subsoiling. The instance quoted of the Lake Agnano, near Naples, proves nothing else. Besides, malaria is very capricious, and sometimes diminishes for some years, afterwards to reappear under a new form. This occurred in the Tuscan Maremme, where, in 1861, the division of the fresh water from the salt marshes was believed to have vanquished malaria, while a formidable epidemic of fever in 1863 showed the necessity of again recurring to warping, after all, the most effective process of improvement. I do not think that trees absorb malaria ; this is shown by the lowest parts of the Agro Romano, which are well wooded, and yet the most unwholesome. Trees may form a curtain, as at Ravenna, between the marshes and a certain tract of land which thus remains sheltered. But, beyond a certain distance the malaria brought by the wind resumes the ascendant. In my report I purposely abstained from expressing any opinion on the intrinsic nature of malaria, simply stating the various theories held respecting the environs of Rome. So long as it is admitted to originate from stagnant waters, how it is produced matters little. But the meteorological data I have collected regarding many Italian towns may hereafter contribute to elucidate the question. The higher parts of the Agro Romano are but a succession of knolls and hillocks, intersected by ravines and deep-set torrent beds. I do not expect that cultivation alone can purify the air, but it will dispose of the numerous small springs and puddles, which are calculated to number over 15,000, and which, although each very small, in the aggregate powerfully contribute to maintain malaria. Cultivators will be interested in removing them, while under the present system there is a motive to foster them, as those damp patches remain verdant, and feed the cattle long after the summer's heat has parched the remainder of the land. Those who believe that cultivation on a large scale (not necessarily inherent to extensive landholding) should be applied to the whole of the

Roman Campagna, err in thinking it a flat and level plain. In point of fact, there is no level country, excepting just along the sea shore and the narrow valley of the Tiber. All the rest is undulating and hilly. In this part some deep soil may be found near the river courses, but the crests on the knolls have only a few inches of earth spread over the solid volcanic tufo, the surface being everywhere sharply inclined. In our climate only hand labour can properly deal with hilly slopes, and those of the Agro Romano must be planted with Vines, Olives, Figs, Almonds, and Oranges, as (except the last, which are of modern introduction) they were in ancient days ; only such cultivation requires a dense population, which now is kept away by malaria. The drainage of the large marshes must first begin to purify the atmosphere ; next, the present system of agriculture may be gradually modified, keeping in the plains extensive cultivation improved by modern appliances ; after that, planting may begin on the hills, which, little by little, will absorb the watery percolations and still further improve the air. Thus in course of time we may see the Roman Campagna restored to cultivation like some other parts of Italy—for instance, the neighbourhood of Novara.—*M. Parco.*

### WORK FOR THE WEEK.

#### PRIVATE GARDENS.

**Flower Garden.**—Little can be done in this department whilst the weather continues so wintery. Protection should be given to all plants likely to suffer, owing to their unseasonable advancement in growth. The finer kinds of Roses, especially standards, should have their tops tied loosely together and protected with some sprigs of broom. For herbaceous plants a layer of rough leaf-mould, tan, cocoa-nut fibre, or similar material should be applied around their necks and over their roots, taking care, however, before applying it to remove the snow. Beds containing Lilies and other bulbous roots should also have a coating of the same material or of rotten manure placed over them. The most tender kinds of shrubs and Conifers should have some dry Fern strewn over them ; clean straw may be used for the same purpose, but it is apt to harbour mice. Broom, Fern, and mats form the best protectors, the latter being supported on stakes. Snow should be removed from the branches of choice trees or shrubs, more especially those of Conifers and other Evergreens, which it is apt to break. All newly planted trees and shrubs should have strong but neat stakes affixed to them. Pruning in general should be discontinued for a time until the weather takes a more favourable turn.

**Conservatories.**—These are now gay with Dutch bulbs, Cyclamens, Chinese Primroses, Cinerarias, Camellias, Azaleas, forced shrubs, Epacris, Heaths, Acacias, and a few other plants. The pretty water-plant, *Aponogeton distachyon* is in full flower, both in the coolest part of the greenhouse and also in cold frames ; it is so easily grown, too, that a large inverted bell-glass, or flower-pot or pan with all holes stopped up, forms a sufficient home for it. Pot, cut back, and start into growth in the warmest corner of the greenhouse, some Fuchsias and Lemon-scented Verbenas. Some Cineraria seed may be sown in gentle heat to furnish flowers late in autumn ; and young Cyclamens may be pricked off into pots or pans. Mignonette should now be sown in pots for early blooming ; plants of that are up should be thinned, and Tree-Mignonette should be trained and tied into proper form. Pelargoniums may be shifted and placed in a warm corner of the greenhouse. Tropaeolums should be trained twice a week, and, as soon as their flower-buds are well set, weak manure water may be freely given to them. Remove dead foliage from Carnations in pots, and stir and top-dress the soil. Divide and re-pot plants of *Isolepis gracilis*, and place them for a time in a moist heat. Selaginellas may also be separated, and potted in a mixture of loam, peat, and leaf-mould in equal proportions, with a good admixture of sharp sand. Borders of these little plants may also be renovated. If a good stock of seedling Ferns is at hand, one or two of a sort may be stuck into a pot containing Hyacinths and Tulips ; they hide the surface soil, and render the pots more pleasing in appearance. Greenhouse Ferns should be kept as dormant as possible yet, especially such as are deciduous, and also hardy Ferns in pots, but a dust-dry condition is injurious.

**Hardy Fruit and Kitchen Garden.**—While the snow lasts little can be done out-of-doors. Soil cannot be turned up with advantage, neither can seeds be sown. Even the planting of early Potatoes, which is a matter that now requires attention, had better be delayed for a short time. If Potatoes must be had very early, start the sets indoors, placing them thickly on light soil, and in a fortnight hence or thereabouts transfer them to a warm border, facing the south if possible, and where the soil is rather light. To prevent snow or frost from locking up, as it were, vegetables required for every-day consumption, rank litter must be freely

strowed over them. Scrape off the snow from a portion of the Celery ridges, and apply 6 inches or so of litter thereon, so that no delay may be occasioned in getting up the crop. For the same purpose remove the snow from amongst a portion of the Leek crop, and place some litter between the rows. A bed of Parsley should be hooped over expressly for winter use, and immediately on the appearance of frost some Pea-stakes, evergreen boughs, mats, or any other material at hand, should be thrown over the hoops; and should very severe frost set in, some Fern should even be placed over the whole. Some Chives for early use may likewise be protected; also some Parsnips and Jerusalem Artichokes; in fact, the two latter should be lifted altogether, the first to be stored and the room given to other crops, the last to be replanted. Turn manure heaps at the same time, saving the roughest litter for protecting vegetables and for covering frames; the more decayed part can be used for spring cropping. Manure and leaves for hot-beds should also be turned and well mixed together. Tools should be repaired, baskets mended, canvas screens for protecting fruit trees put in order, nets for placing over seeds got ready for that purpose, and many other things done for which time cannot be spared hereafter.

**Ice-houses.**—These may now be filled. Whatever may be their form the following points must be observed, viz.,—thorough drainage, the outlet being in the form of the letter S, and linings of clean dry and non-conducting materials; over the floor, which should be firm and level, should be put some faggots or a wooden grating to prevent the ice from touching the floor, which is of a higher temperature than that of the ice; therefore, faggots covered with straw, being non-conducting substances, are useful in such a position and are also essential for drainage. The sides of the pit, house, or cone should be protected from the external atmosphere by a thick and close lining of clean straw, Heather, or Fern, and the top should be covered or thatched with the same materials. Sunk houses or pits cannot always be sufficiently well drained. In such cases a conical mass should be erected above the ground level, in a position partially shaded by trees and having a northern aspect. A blunt-ovate or spherical shape is best, and is that which is generally adopted. Both for heaps of this kind and for ordinary ice-houses, the cleanest and best ice should be selected, and in the operation of packing broken with wooden mallets, the small portions being made to fill up the interstices between the larger lumps, so as to make all solid. Some clean freezing water may also be advantageously poured over the mass with the intention of making all solid.

#### NURSERIES.

**Indoor Department.**—Mats should be run along the upright sashes around the various houses, in order to economise heat. A narrow straw mat should be placed before each door, to prevent the ingress of cold winds. All cisterns should be protected from frost with straw and mats; pumps should be encircled with straw ropes, and a lining of litter or straw should be applied to the sides of frames. Mats and litter should also be placed over the sashes of these in frosty weather, and in the event of a continuance of piercing frosty winds or snow the covering may remain undisturbed for a day or two, but immediately the least thaw comes all snow must be removed. Rather than endeavour to maintain an extra high temperature during cold frosty weather allow it to decrease a degree or two. Sheds should be cleaned out and soils of various kinds hoosed, so that they may be in a usable condition when required. Pots should be washed, dried, and laid in proper position according to their respective sizes. Crocks should also be washed in a big tub or trough by stirring them round roughly with a strong stick. When thoroughly cleaned they may be taken out, sifted, the larger pieces broken into suitable dimensions, and laid up in heaps to dry. A portion may be pounded rather finely for mixing amongst the soils used for many plants. Charcoal should also be obtained and stored safely, likewise chips of fine sandstone, for which the roots of many plants have a particular liking. New labels should be got ready and old ones repointed and made smooth with a sharp knife. Sphagnum, if wet, should be placed on an elevated wooden framework to dry. In propagating pits, more particularly those for stove and ordinary soft-wooded plants and seedlings, a high temperature must be maintained, whereas in the ordinary grafting and hard-wooded greenhouse plant pits, a minimum temperature of 50° is sufficient. If the tops of sub-tropical plants have been used as cuttings, encourage the side shoots on the stock to grow by means of heat and moisture, and as soon as the young shoots are a few inches in length use them for the same purpose. Continue to sow seeds as they are bought or imported. Prick off in sandy soil liberally enriched with leaf-mould, Lobelia and Mimulus seedlings; also any others that are large enough. Prick off seedling Yuccas and place them in the coolest portion of the propagating house. Sow some Statice seed, also seeds of Camellias, Azaleas, &c., for stocks

for grafting on. Take off the tops and points of shoots from the sides of plants for cuttings. Repot some of the Pitcher plants in good spongy soil. Marantas may also be divided and potted singly; indeed, such stove plants of which increase of stock is the object, should be increased vigorously, and young plants potted and kept growing. It is not advisable, however, to keep established plants growing during the winter months. Roots of Cannas should be started into growth in a few inches deep of light soil placed on a bench in a warm pit, or they may be potted; but by the former method they can be lifted and divided more easily, and afterwards each shoot may be potted singly. Seeds of Cannas may also be sown. Dahlias may be started in any position in which heat and moisture can be applied, and the young shoots should be taken off and inserted as cuttings when they are 2 inches or so in length.

#### MARKET GARDENS.

Winter has come at last, and though much needs to be done, it would be unwise to attempt to plant, or sow, or dig, whilst the weather continues as it is. Seeds would perish if sown now, plants would die if transplanted, because there is no heat in the soil to excite vegetation; we must therefore direct attention chiefly to the manure heaps. Turning them, shaking out the rankest for protecting material, and carting the decayed to the various quarters to be manured, must constitute the principal operations at present. Should the roads be soft, however, the carting may perhaps be deferred for a time. Mushroom beds should have the snow scraped off them, and additional coverings applied to them if necessary. Rhubarb, Seakale, and Asparagus beds should also be relieved from snow, and extra linings applied to them, in order to maintain the required amount of heat. Radishes in beds must be closely protected, and birds particularly watched for, being deprived of other food, they do not hesitate to avail themselves of whatever seeds they can pick up. Should frost be likely to continue, litter should be spread over Celery ridges, and between rows of Leeks, to prevent these crops becoming "locked" up. Over Endive on ridges some rank litter should also be strowed, to save it from frost. Onions, Carrots, Celery, Lettuces, Cauliflowers, &c., in frames should likewise be protected. With the exception of Onions, Carrots, and Celery, a little frost will not injure the others. This is commonly a busy time in the way of transplanting Lettuces, but that operation must now be delayed until the ground is in better condition for their reception.

**The Proposed Park for Stratford and West Ham.**—The committee appointed at a recent public meeting in Stratford to carry out this matter, have issued an appeal, in which they state that no parish near London has increased more rapidly of late years than West Ham. Not long ago it was a pleasant, well-to-do rural suburb; it is now fast becoming a large manufacturing town. It already numbers more inhabitants than some whole counties, and it has only 8,000 fewer than "the City of London"—an increase of more than 60 per cent. within the last ten years. A golden opportunity occurs for securing a beautiful, well-timbered park of 80 acres, including the garden allotments, in the very heart of this vast population—an oasis in what will, in a few years, become a desert of bricks and mortar. It is a case of "now" or "never;" for if not secured at once the park will shortly be cut up for building, and will soon be covered with small houses. The owner of the park, Mr. John Gurney, offers it solely for a public park, on the following liberal terms. He assumes that its market value is £25,000, which the committee, after careful investigation, believe to be a moderate estimate. Towards this amount he guarantees that members of his family (who, from their long connection with West Ham, retain a warm interest in its welfare) will subscribe the munificent sum of £10,000. In addition to this, Mr. Gurney expresses himself willing to allow a portion of the balance (say one-half) to remain on mortgage for five years, at a moderate interest. Thus the immediate outlay necessary to secure this great boon to the parish would be comparatively small. The committee, therefore, urge that it would be most unwise not to take advantage of this generous offer. As to the question, How can the money be raised? the committee think the means cannot be found in the rates, which already amount to 8d. in the pound. If done at all it must be done by private effort. The residents and owners of property in the parish must first show themselves in earnest, and ready to do their utmost, and then a successful appeal for help may be made to the public, and especially "the City." If the park be purchased, it is proposed to vest it in the unmentioned trustees, who have consented to accept the trust:—T. C. Baring, Esq., Sir Antonio Brady, T. F. Buxton, Esq., J. Gurney, Esq., Andrew Johnston, Esq., and Colonel White. It is also proposed that the management of the park be in the hands of a governing body, to be chosen by the subscribers. As it is intended that the park shall be kept as a park, and not as a garden, the expenses of maintenance need not be large.

# THE GARDEN.

—o—o—o—  
 "This is an art  
 Which does mend nature: change it rather: but  
 THE ART ITSELF IS NATURE."—*Shakespeare.*  
 —o—o—o—

## RENOVATING THE KITCHEN GARDEN.

My attention has been directed to this subject by reading a paragraph in *THE GARDEN* (see p. 531) in which the writer describes a mode of trenching and manuring adopted by him. His system has, I think, only one recommendation, namely, expedition. He states that his mode of trenching takes very little longer than plain digging, and that he does not bring up too much sub-soil to the surface at once; still the ground is partly loosened and allows water to get away. Are we gardeners, then, to adopt a system the chief merit of which is expedition? No; if we can do but little, let us do that little well and thoroughly. Trenching is a most important operation, and ought to be done well and wisely. A man with a strong arm can cast out a trench well, but it requires both judgment and experience to decide how much, or if any, of the subsoil should be placed upon the top. Subsoils vary so much that no certain rule or correct guide can be laid down upon this point. But there is one operation that is applicable to every variety of sub-soils, (and if it is neglected, no trenching can be said to be efficiently carried out), that is, loosening and breaking up the bottom of the trench by spade or mattock, as the case may be. The more thoroughly that is done, the greater will be the ultimate benefit resulting from it. Another very important point to be considered is the proper season in which to trench. No doubt autumn is the best time for such work, and the earlier in the autumn it is done the better, before the surface soil parts with its heat.

The next consideration of importance is the application of manure during the operation of trenching. For my part I never trench in manure, and I would fain hope that the practice of burying manure in the bottom of trenches is not now generally practised. The slightest knowledge of chemistry and of the ordinary operations of nature shows such a practice to be a waste of both matter and means. I have an impression that the proper application of manures is just one of those subjects on which many bestow little thought indeed. With regard to farm-yard manure, do we not often defeat the very object we wish to attain, by allowing it to expend its best properties in over-fermentation, or permit them to be washed out by exposure to heavy rains when laid behind some wall or fence awaiting a favourable opportunity to be carried into the garden? Many have a wrong conception regarding the relative quality of fresh and rotten farm-yard manure. Anderson, in his "Practical Gardener," says: "In most cases I would recommend the application of manure that has undergone a degree of fermentation in a hot-bed." Where the dung has been properly manipulated and prepared before being built up in the form of a bed its quality may not be diminished much, but in the majority of places the dung used for hot-beds does not undergo the preparation necessary to secure all its qualities, and for that reason it is of comparatively little value. But the question, pro or con, in regard to fresh or rotten dung, must be decided by the judgment and experience of the gardener. On this point he will be guided in his choice by the nature of the soil he has to enrich and stimulate.

After he has made his choice, a most important operation yet remains, namely, the application of the manure to the soil. All will agree that the better the two are incorporated the greater will be the beneficial result; indeed, to effect this ought to be the first consideration of every cultivator; but this cannot be well done when both soil and dung are in a moist condition, and for that reason dung ought to be, as far as practicable, applied to the soil when both are in a proper state to mix freely together. Even under the most favourable conditions this object may be defeated by an unskilful workman. Many imagine that it needs but little judgment to dig a piece of ground. My own opinion is so much the reverse of this that I would dig all my own ground myself, were it possible

for me to do so. In digging, the workman ought to keep a deep and wide opening, so that the newly turned earth and dung thrown well up against the opposite ridge may mix together in rolling down the face of the trench. In heavy soils a steel fork will be found an excellent cultivator. Indeed with me it has entirely superseded the spade for spring "pointing"; in the hand of a skilful workman it pulverizes and disintegrates heavy moist soils in a manner that no other garden tool with which I am acquainted will do. While our agricultural brethren are improving the soil by all kinds of mechanical appliances, are we putting forth our energy to do the same by manual labour? This question I shall leave my readers to answer. But it is to be feared that in many poorly manned places the flower garden often absorbs a part of the labour and attention that ought to be expended upon the kitchen garden. Many may think this a groundless charge against "the object of their affection," but it is nevertheless a case that can be proved. Are there not dozens of medium-sized places in which is made a great show in bedding-out that have now no more strength in the way of manual labour than they possessed twenty years or more ago, when bedding-out was little practised? Therefore, if this be so, some department must suffer. Do we not hear complaints on all sides that old gardens are wearing out; one will not grow Carrots; Onions cannot be grown in another, and some will grow neither the one nor the other. Is there no remedy for such cases?

That the soil in many kitchen gardens becomes so much worn out, that it is often with difficulty crops are raised in them, is a fact too well known to need confirmation. A combination of causes over which a gardener has little or no control often leads to this state of things. A want of sufficient manure, or of strength to keep the garden in a high state of culture, will bring about this result sooner or later, even in the best of soils. Another cause leading to this is over-crowding with overgrown fruit trees. This had rendered the kitchen garden here "a perfect wilderness." The old Apple and Pear trees had been allowed to grow "in wild luxuriance" for well nigh a century. Their great moss-covered boles, hollowed out by age, made a home for rats and other vermin, from which they could not be driven except by the old Border method of "fire and steel." A reluctance upon the part of the family to have these "encumberers of the ground" disturbed "in their time," led eventually to the garden becoming, even in the open quarters, almost valueless as regards the quantity of the vegetables grown upon them. This is doubtless an extreme case, but it is not an exceptional one; for the old system of crowding vegetable gardens with fruit trees frequently led to a state of things similar to what I have described. In our case matters had got so bad that nothing but a thorough and complete renovation of the whole garden was of any avail. With my employer's sanction, therefore, I cleared the garden at once of well nigh the whole of the old trees, lifted the walks and relaid them 10 inches higher than they were before, and filled in the borders around them with fresh soil, mixed with well-rotted dung, to a height of 8 inches above the level of the walks, altogether making a depth of 18 inches of fresh soil. After a thorough preparation I planted those borders with dwarf fruit trees, at a distance of 10 feet from the walks. At the same time I covered with fresh soil and compost about a seventh part of the garden, to the same level as that of the surrounding borders. For six successive winters I have continued to cover a portion of ground, in extent equal to that done the first year. Next winter will see the whole garden renovated from end to end. This may be considered a slow process, but it is not too slow to accomplish the object aimed at, and besides it has been done at an outlay little beyond the ordinary expenses connected with the garden. By this process, too, I have been enabled to establish fresh plantations of fruit bushes, Asparagus, and Strawberries upon the newly-prepared soil, before doing away with the old. The dwarf fruit trees planted six years ago are now so well established that I am just now rooting up the last old tree. The vegetables now produced in the garden are of superior quality. On the 15th of last October I was enabled even to gather a dish of young Peas.

I may, however, remark that late Peas are by no means an

uncommon thing in our northern counties, when frost keeps off until late in autumn. The most noticeable point connected with the Peas in question was their exquisite flavour at such a late season. The variety was "The King of the Marrows," which with me is an invaluable Pea, bearing every autumn until killed by frost. The question is, however, simply this: Is the process of renovation just named practicable in the generality of places? I say yes; in many cases fresh soil would be preferable to dung itself, which may have been applied year after year to the same ground for several generations. Another advantage gained in renovating a garden with soil is that where the staple is light, soil of a heavier texture may be added to it, and *vice versa*, when the original soil is heavy, a lighter compost might be applied.

The next most important consideration is, will the ultimate benefit repay the labour and outlay attending such a system of renovation? Doubtless it will, where the requisite material can be conveniently had; but, under any circumstances, I consider the kitchen garden so valuable that labour and expense ought to be only a secondary consideration in making it every thing that skill can accomplish. No department requires more forethought than the kitchen garden. J. T.

### NOTES OF THE WEEK.

— A MEETING will be held this day, at noon, in the Charing Cross Hotel, to discuss the matters to be brought forward at the adjourned meeting of the Royal Horticultural Society next Tuesday.

— NORTHUMBERLAND HOUSE is doomed. The object for which this noble mansion is to be acquired by the Board of Works, at the round sum of half a million of money, is the connecting of the Thames Embankment with the system of thoroughfares that converge at Charing Cross by a street which is to pass over its site.

— THOSE interested in sending plants or seeds to friends abroad will do well to bear in mind that under authority from the Postmaster-General of India parcels not exceeding 50 lbs. in weight, and 2 feet by 1 foot in size, and £20 in value, are now conveyed by the Peninsular and Oriental Company from London to any post town in India at a uniform charge of 1s. 4d. per lb. Full particulars may be obtained on application to 122, Leadenhall-street, E.C.

— At the meeting of the Royal Horticultural Society, held on Wednesday last, Mr. Green, gardener to W. Wilson Saunders, Esq., exhibited some exceedingly useful plant labels. They consisted simply of cast iron of various forms for large plants; that part which is inserted in the earth was painted lead colour, and that for writing on white. After the white portion has become thoroughly dry a coating of black paint with a goodly admixture of drying incorporated with it, is applied over the white, and four or five minutes afterwards the name may be written on it. A flat piece of board with a hole in it for the reception of the shank was also exhibited, and by means of this a rest for the hand in writing is obtained, without any fear of touching the paint. The names are written with a pencil consisting of a piece of wire inserted into a wooden socket. The writing is white, somewhat resembling that done with a fine camel-hair brush, and it is extremely lasting; for labels made and written on in the manner described were quite as good, clear, and distinct after five years' wear as those newly written on. For small pot plants zinc labels painted and written on in the same way are neat and legible. No delay need be experienced on account of wet paint, for a certain quantity can be painted first, and after a lapse of five minutes written on without halting.

— AMONGST subjects for competition for which prizes are offered by the Scottish Arborescent Society during 1873, we find the following:—For the best and approved report on the most extensive, complete, and judiciously arranged Arboretum, the "Lawson Prize" of five guineas; 2nd prize, a medal. The author must describe the positions as to soil, exposure, elevation, &c., of the respective species and varieties of trees reported on, and state their ages, treatment, cost, and mode of planting adopted. Arboretums reported on in 1872 are excluded.—For a full and complete, but succinct and well-written account, from published descriptions, with authorities distinctly quoted, personal observation, and experiment of the history and present state of the cultivation in Great Britain and Ireland of *Cedrus Deodara* (C. Libani, and C. atlantica, all now classed as one species). Special medal, value three guineas.—For an approved report on the results obtained by experience of seedlings of Conifere, being the produce of trees grown in Britain, as compared with plants obtained from foreign-ripened seed. A medal.—For an approved report on the natural history of beetles and other insects

which affect Conifere—their modes of operation upon the tree, and suggestions as to a remedy for their attack. A medal.—All essays and reports must be sent to the secretary, Mr. John Sadler, Royal Botanic Garden, Edinburgh, not later than the 25th of September next.

— MR. STEPHEN MAPLE, under-gardener to F. Philips, Esq., Lee Priory, Wingham, has met his death under singular circumstances. He was training a creeping plant of a poisonous nature (probably a *Euphorbia*), when he was pricked in the hand by one of the thorns. Mortification set in, and he died in great agony four days afterwards. He was 77 years of age.

— WE learn, from the *Journal of Botany*, that a sixth century of M. C. Cooke's "Fungi Britannici Exsiccati" has appeared. Several new species are included. *Uromyces Salicorniæ*, *Adocephalum roseum*, *Peziza Typhæ*, and *Venturia atramentaria*. *Helotium puberulum*, *Fekl.*, and *Capnodium salicinum*, P., two species not previously found in Britain, are also included.—The herbarium of Prof. Hoppe has been acquired by the Gymnasium of Salzburg. Prof. Fee, of Nancy (late of Strasbourg), has presented his herbarium to the Museum of Rio Janeiro. The herbarium of Prof. Meisner, of Bale, has been purchased for Columbia College, New York.

— THE Executive Committee of the American Pomological Society have decided to fix September 10th, 11th, and 12th for the meeting this year in Boston. Although sixty acres of that city is burned, we are pleased to learn that no part of their disposition to welcome their friends has been consumed by the devouring element. The work done by this society well deserves the attention of European pomologists. Much of the vast improvements witnessed in America of late years, in reference to fruit culture, is owing to the wise action of this society. In its catalogue the value of every important variety of fruit in each State may be seen at a glance.

— A SMALL district round the city of Florence seems to be at present the chief, if not the only source of Orris-root. The plants yielding it are *Iris florentina*, *I. germanica*, and *I. pallida*, and the scraped rhizome is the portion of the plant which occurs in the market as Orris-root. Large quantities of these roots are used by perfumers for the purpose of blending with other essences, and it is also largely used for tooth powders, and for the composition of what is commonly known as violet powder. Orris-root contains an essential oil, which is obtained by distillation, in the form of a fatty substance similar to Cacao butter. This substance is yielded in very small quantity, and is even more costly than otto of roses; it possesses all the fine aroma of the original root.

— M. ROEZL, on his return to America last year, for the purpose of continuing his botanical explorations in the western regions, met with a serious loss at Denver City (Colorado). Before setting out on an excursion to the Rocky Mountains, he entrusted nearly all his money (20,000 francs) for safer keeping to the landlord of his hotel. During his two days' absence the book-keeper of the hotel (a Dane) contrived to get possession of this money, and decamped with it to the mountains, where pursuit was out of the question. We do not know whether the American law will afford M. Roezl any redress from the landlord who took such bad care of what was confided to him, but we trust that reparation will be made to him. Notwithstanding the unexpected and very embarrassing diminution of his resources, M. Roezl proceeded undauntedly and hopefully on his way westward.

— DR. MEYMOFF TIDY, who is acting as medical officer of health for the City during the temporary absence of Dr. Letheby, reported the seizure and destruction of a large quantity of rotten figs which had been found at some of the City wharves by the sanitary inspectors; and he further stated that an enormous quantity of bad figs had been imported into this country, and now laid at wharves in bond. These figs, which had been bought up to be used as food, in the shape of jam, were full of maggots and were quite rotten. They were principally used because their seeds gave the jam the appearance of being made from *bona fide* fruit, and they were mixed with seeds, the nature of which he had not yet been able to find out, but which in the market were called "Turkish seeds." The poisonous compound, which could not be used until its nature was thoroughly hidden from ordinary observers, was mixed with one-tenth part of Raspberry jam, and was then sold under the name of "family jam," "household preserves," &c. These mixtures were sold to poor persons and children in small quantities, frequently on pieces of paper, and lives must of necessity be lost through its becoming an article of consumption. He had taken the trouble to purchase some of the jam as it was sold retail, and by analysis had discovered that those who made it had not hesitated to use common glue to cheapen the compound. He received from the commission power to force open and examine the boxes of Figs at the wharves where he knew them to be lying, and to destroy them.

THE INDOOR GARDEN.

DAVALLIA MOOREANA.

THIS is one of the most beautiful of Ferns, and one that will eventually stand in the first rank amongst exhibition kinds. It is a native of Borneo, whence it was introduced to the nurseries of Messrs. Veitch and Sons, of Chelsea, by their collector, Mr. Thomas Lobb. Its rhizomes are rather shorter than those of most of the Davallias, are covered with dark brown scales, and are more inclined to conceal themselves in the soil than those of the majority of the genus, many of which have such vigorous rhizomes that not only do they traverse the soil, but project over and down the sides of the pot in which they are grown; or if in suspended baskets or on the trunks of tree Ferns, they twist around them, and under favourable circum-

pale green. Ordinary stove treatment suits this Fern well; but it will also grow and flourish in an intermediate house. A low temperature and comparative dryness, but not too much so in winter, causes it to form large fronds in early spring, when additional heat and moisture are afforded it.

W. F.

FORCING CAMELLIAS.

“FORCE Camellias! Yes; force the buds off with a rush, like a shower of fast-falling hail, excite the plants prematurely, weaken them beyond the power of bud-forming at all, convert them into evergreen bushes—fresh, glossy, shining, but flowerless!” Well, I admit that all that and more and worse may be done by attempting to force the Camellia. More; that as generally understood, the Camellia cannot and ought

Davallia Mooreana.

stances form as it were a net-work enveloping the basket or trunk on which they may be grown. The shortness of the rhizomes in *D. Mooreana*, and their partiality to the soil, as well as the stately habit of the plant, plainly illustrate that pot culture is the most suitable method of growing it. The entire length of the fronds of a plant of this Fern, at present in Messrs. Veitch's nursery, is nearly 4 feet. They are extremely handsome and gracefully arched. The outline of the pinnae is triangularly acuminate, the base being slightly narrower than the length of the sides. These are again sub-divided into numerous little divisions bearing a great number of small blunt oblique segments. The fronds are densely laden with elongated cup-shaped sori, deeply set on the under side, and they consequently give the upper surface a conspicuously dotted appearance. The colour of the leaf-stalks is pale green tinged with brown, and that of the upper surface of the fronds

not to be forced. That, moreover, firing has, as a rule, resulted in forcing off the buds and injuring the plants. Still, I am about to advocate the forcing of Camellias, and to affirm that they rank among the best and most effective plants for that purpose; nay, that Camellias cannot be enjoyed at the right season without forcing. What, it may be asked, is the best season for the Camellia? Its flowers are ever useful—always beautiful. But if there is a time when their beauty culminates and their usefulness likewise, it is from October to January inclusive. During these dull months their pencilled beauty comes out with a delicacy and perfection of colouring that is seldom equalled at other seasons. Spring sunshine plays havoc with the colouring and duration of Camellia blossoms. Perhaps November fogs, if allowed to lie upon them, are almost equally destructive; but the one is easier mastered than the other. A careful use of the watering pot, the pre-

vention of drip, and a sweep of dry air from the heating apparatus, will prevent and chase away the damp. Camellia blossoms, too, seem to glory in the quiet unexcited days and nights of the dead season. They expand slowly, and never are they more lovely than when half open. As the pulse of life beats quicker in spring, we can hardly say that we have Camellia flowers, so soon are they over. Camellias are November's Roses—Roses of the best in all but fragrance; they delight all hearts. As to their forcing, I speak from experience. I had once the care of six magnificent plants of double white Camellias. By peculiar management (once for all only) they were led to flower from November to January—one of them nearly a month earlier. Two fine single white Azaleas were treated in the same manner, and flowered at the same time. These eight plants with a fine specimen of Rhododendron arboreum, and another of R. Russellianum, made a summer-tide beauty in a large conservatory every year, all through the winter. How was it done? Nothing could be simpler. There are two seasons for forcing. This is well recognised in fruit culture, but seems to have been much ignored in the forcing of many flowers, especially the Camellia. In the last state, preceding flowering, it is a bad forcer. The buds are impatient of warmth, when they are about to open. They have a great deal to do to unfold all their closely packed petals, and they must have time to do it in. But in the making of their growth, and the formation of their flower-buds, they enjoy genial and liberal treatment. They may even be exposed to a tropical climate, not only without injury, but with apparent benefit, provided it is moist enough. Shade them from bright sunshine, preserve a moist atmosphere, and feed the roots freely, and fine shining leaves will be made in abundance, and any number of flower-buds will be set on the ends and sides of the newly-made wood. Continue the warm treatment until the wood is partially ripened, the flower-buds well plumped-out, and then gradually reduce heat and moisture, and finally remove the plants into a cool house, or a sheltered spot out of doors, towards the end of July. Finally, in September let them stand behind a north wall. On the first of October house them in a genial temperature of 45°, and almost immediately the buds will open large and full, and the flowers unfold in all their freshness and beauty.

In fact the Camellia forces well, but the forcing must be given about eight or ten months before the flowers are required. You want Camellias to bloom next October and November; very well, begin to force the plants now, hurry growth on in a genial temperature, even though it hurries off all the blossoms. Place the plants in a Vinery or Peach house "at work," and keep them there until the growth is finished and the flower-buds are set. In the pushing, setting, and maturation now and through the summer months consists your forcing of Camellias for next autumn-tide. Then you will only have to let loose the beauty that is securely bound and treasured up now. In a word, all this is the merest truism in regard to the forcing of Grapes, Peaches, and other fruits. Three parts at least of the forcing for one season have invariably been done the year before. We have only to apply the same rules to Camellia forcing to reap rich harvests of bloom from October to January. The process too becomes easier every year. Sometimes the plants need no forcing after the first season. This was the case with the large ones already adverted to. Early Camellias were indispensable. I took charge of them in November rather out of health and scant of bloom. About the middle of December they were plunged in a bed of tan in a forcing house. The few flowers came out and went off with a rush, but they made fine growth and set hundreds of buds. By the middle of June they were in the open air, and some flowers were out in September; but the great show lasted from October to January. As to succession of blossom, a great deal may be done to provide it in the choice of buds of all sizes when thinning. If the largest only are left the flower is soon over, if the smallest are selected, it will be late; but by leaving some of all sizes we have flower early and late and all the way through.

Again, Camellias once forced, come naturally early ever afterwards. My plants had never any special treatment but once. When the flowering season was over they were simply moved to the shadiest side of the conservatory, to make

their growth, and they began to flower ever after in October. The Azaleas *phœnicea* and *alba* and *Rhododendrons* did likewise. Azaleas, however, bear forcing well at the flowering period as well as in the previous summer—though the riper the wood, the more plump the blossom in the summer, the less forcing is needed in the winter and spring. Camellias, on the contrary, only can be forced successfully, say eight months, before they are wanted to be in blossom. I almost wonder some nurserymen do not turn their attention to the culture of a class of Camellias specially for forcing. Their capacity varies somewhat in regard to this, and I would almost venture to state that the less double the better they would bear direct heat to their blossom buds. The single kinds furnish nice flowers for button-holes. Some of the semi-double sorts, such as *Elegans*, *Lady Campbell*, *Tricolor*, &c., force well directly while no variety with which I am acquainted refuses to be forced in the indirect way now prescribed. D. T. FISH.

#### HOW TO FORM TREE MIGNONETTE.

MANY have been of opinion that tree Mignonette was a distinct variety from that in ordinary cultivation, and in many gardens it was thought necessary to propagate it from cuttings in order to perpetuate its arborescent character. Time, however, has eradicated that notion. Nevertheless it must be admitted that by a process of selection, by saving seeds from the strongest plants bearing the largest flowers, a vast improvement has taken place in Mignonette, and that several varieties, more or less permanent, are now offered in seedsmen's catalogues; but the arboreal character of Mignonette depends entirely upon culture and training. Tree Mignonette may be grown to any size, from 1 to 6 or more feet in height, and may either be trained to a single stem with a bushy head at the top, like a standard Rose, or as pyramids. The latter form I consider to be the most natural and pleasing, although, at the same time, it may be desirable to grow a few standards also. To have strong, well-developed Mignonette trees for autumn and winter blooming, the seeds should be sown in April in small 60-sized pots, three or four seeds in a pot, and placed in a warm frame or pit near the glass. Although Mignonette will grow in almost any kind of soil, still, if large plants are wanted for the conservatory, they must be treated liberally, if they are to have any degree of permanence, as Mignonette in pots under glass, with the seeds and dead flowers constantly picked off, assumes a perennial character. I have generally found, however, that after two or three years the plants lose vigour, and that though there is no question about their freedom of flowering, the flowers lack strength and substance; therefore, unless very large specimens are wanted, it is as well to raise at least some of the plants annually. The best compost for Mignonette is a good sound loam, with about one-fourth of its bulk of thoroughly decayed manure, reduced almost to the appearance of black mould, if obtainable, with a good sprinkling of charcoal broken small, or old mortar or plaster from old buildings, and in all cases let the pots be well drained. When the young plants are large enough to distinguish which is likely to make the strongest specimen, let that one be retained and the others drawn out, so as to have only one plant in each pot, and let that be secured to a short stake to keep the stem straight. Shift the plants into larger pots as they require it, never allowing them to become pot-bound, and keep the leader always in advance, pinching off all flowers, and any shoot that seems desirous of outgrowing its fellows. As the season advances the plants may be placed in a deep, cool, rather moist pit, or any place, such as a north house, where the heat of summer will not, by causing the undue ripening of the wood, check the growth and push the plants into flower. Till the end of August the object should be growth; therefore, keep the plants in a growing atmosphere, and see that they do not get pot-bound; and let each plant be supported with a good stake in the middle of the pot, with the main stem tied to it. But any one who wishes to see what size Mignonette is capable of growing to under favourable conditions, should select one or two of the most thriving plants when they have attained a height of 3 ft. or so, and plant them out in good soil in the conservatory border, and only allow them to bear a few flowers the first winter. Plants so treated without check, and attended to in pinching and training, will show that the prefix "tree" is not a misnomer. If standard plants are desired, the side shoots must be pinched back to one pair of leaves—that is, leave one clear joint from the stem. When the leader has attained the requisite height and the head is formed, those little spurs may be cut off. In potting, the last shift should not be later than the end of August; and when blooming begins, a soaking of weak liquid manure may be given occasionally. E. HOBDAV.

## DRUMLANRIG CASTLE.

ONE can hardly fail, on approaching fine demesnes in Scotland, to be struck with their extent and apparent publicity. Some of the parks and woods are almost as large as an English county. The estate of Drumlanrig, for instance, covers nearly one-third of Dumfriesshire. The home grounds are of vast extent, stretching out in all directions from the castle, until the boundaries merge into mountain moors or sheep-walks. There are neither approach lodges nor boundary walls. All is open and free, and apparently boundless. One drive alone, of rare beauty, following the rocky gorges of the river Nith, extends for seven miles, and is worthily called the Duchess's drive. A grand road, 30 feet wide, with broad turf, and noble lines of trees on each side, rushes off and out from the front door of the castle, straight as an arrow, until it loses itself among the hills. Another fine road skirts a noble wood on one side, and a home farm on the other, all the way from near Thornhill to the castle. Of green drives through the most charming scenery, there seems literally no end: there is, I believe, something like 80 miles of them. The scenery is of the richest description. The ground is what would be called rolling, and it rolls up into real mountains on several sides, while the corn-fields are as fertile as those of the south, and the herbage in the valley of the Nith is splendid. All varieties of scenery are within view. Rising from the walks and roads the eye reaches rolling sheep-downs and far-reaching forests, magnificent trees in parks and pleasure ground. Then comes the regions of brown or glowing purple Heath, and shaggy woods, or towering mountains, or far-reaching arable land, with the Nith, or other rivers, winding about like silver shields, and threatening to overflow the valleys with their raging, foaming waters. These Scotch rivers, tumbling down headlong and impetuous, give life to the landscape. Of such character is the Marr burn, that bounds the flower garden on one side. As to the castle it is impossible not to be struck with its beauty and grandeur. On the east rises the Queensberry range. The views to south, south-east, and north are very extensive and beautiful. Many of the trees in the park are very fine. Near the castle is a grand Sycamore over 6 feet in diameter. The forests, which are extensive, are of modern date, and planting is still going on.

There is a flower garden here of some fifty acres in extent, that was beautifully, variously, and richly furnished last autumn, though rain poured down almost the whole summer. The style around the castle is what has been facetiously called the "fortification style." These grand old castles no longer need the support of cannon or stalwart heroes clothed in iron mail; but they do need the support of bright flowers, noble terrace walks, and bold massive retaining walls to let them down with dignity, as well as grace, to the smooth level of modern life. The south side and east and west ends are based with a fine level gravel walk, about 30 feet wide. Then follows a slope of turf at a sharp angle, of great depth. At each end of the building, on the next level, is an even space of ground some 70 yards square. One of these, the west end I think, is laid out as an herbaceous garden, chiefly furnished with autumnal-flowering and sweet-scented flowers, such as Carnations, Roses, Phloxes, Mignonette, Asters, Stocks, Fuchsias, Pelargoniums, &c.—a rich assortment. This garden is bounded by masses of Laurel, rising one above another like terraces. These are pruned once or twice a year with the knife, so that no leaf is cut asunder, and they are kept to a height of 3 or 4 feet. On one of those wide Laurel terraces fine old Yews rise up at intervals, in massive sombre grandeur. These are supposed to be as old as the castle itself, viz., about two hundred years old. These Laurel banks or terraces are important features at Drumlanrig. They form one side of the chief flower garden, cover many acres of ground, form walls of green to some of the walks, and lose themselves among freer or more naturally-grown trees and shrubs. On the ground at the other end of the castle is an American garden, which is chiefly furnished with noble specimens of Rhododendrons that were planted, I believe, when the present duke attained his majority. These are illuminated in autumn by a few flowering plants. Both of these end gardens are flanked, next the grand terrace walks, with a chain pattern, in which, in

the one, the centre circles are filled with Golden Chain, in the other with Crystal Palace Gem Geraniums; and the sides are filled in with the dwarf blue Ageratum and the Tropæolum Cooperi. This threefold chain of bright colours had a very chaste and pleasing effect. Then follows a noble promenade of gravel, about 250 yards long and 24 feet wide, bounded with a massive balustraded stone wall over 20 feet high from the lower side. This noble walk completes the secondary base, as it were, of the castle. It skirts the bottom of the steep turf slope, and the scrollwork outside the mixed and American gardens, and overlooks the entire series of flower gardens on lower and different levels to the south. It is a magnificent finish, a noble promenade—speaking of simple grandeur—worthy of its position, and one which adds dignity to the castle. From this terrace the lower gardens are nearly all under the eye. Fine marble flights of steps lead down to the lower level.

Immediately under the terrace walk there is a border, and the wall is well furnished with Roses, Magnolias, Maiden-hair tree, Clematises, Paulownia imperialis, trained and pruned close like a Pear tree, Virginian Creepers, Corydalis lutea, Tropæolum speciosum, Laurustinuses, &c., all in remarkably fine condition; while lovers of Ferns are charmed by the sight of myriads of Asplenium Trichomanes springing out from, and adorning with rare beauty, every crevice. Immediately in the centre of this space, the Heath garden covers an area of nearly 5,000 yards. The groundwork of this is of silver sand, and through this massive lines, 20 feet wide, of Mountain Heath, closely clipped, meander along curves of elegance and lines of beauty in all directions. The centre is arranged on the parterre system, and filled with flowers, the beds being edged with stonework interlaced with white sand. Lest, however, so much brilliance and whiteness reflected by sunbeats should dazzle the eye, we have only to look to the west, and on a somewhat higher level we behold an acre of specimen Hollies, Yews, Cypresses, and other trees and shrubs; or if one wants more colour, turn to the east, and in the lower white sand garden will be found beautiful lines of bright colours, distinct in outline and furnishing from those in the upper garden. Here the corresponding space filled by Heath in the other garden is converted into a pretty margin of diamond-shaped beds, defined by Box, and traversed by paths of white sand. The centre of the design is formed of flower beds on grass and gravel, and is further furnished with upright Junipers.

All this, however, is but as it were the porch to the flower gardens, properly so-called. These occupy a sort of irregular plateau, reaching almost the entire distance from the gardens in question to the Marr Burn that skirts the bottom boundary. The chief space here is intersected by the main walks, one running east and west for 350 yards, the other north and south for 150 yards. They are 20 feet wide. The beds and scrolls are of great size, and most of them are surrounded with massive edgings either of stone or of shrubs and trees, such as common Yews, Portugal Laurel, hardy Heaths, Cotoneaster microphylla, common Oak, Beech, variegated Honeysuckles, Vines, &c. These edgings are kept clipped to about 6 inches square. The centre is richly furnished with an eye of rich Palms, Echeveria metallica, Yuccas, Beet, &c.; around this balancing beds are formed with variegated Yuccas, Beet, Pelargoniums, &c. Here too are placed some noble marble vases, granite seats, &c., giving or receiving dignity and importance from the surrounding vegetation, of fine foliage plants, flowers, shrubs, trees, and masses of Rhododendrons and Roses. One of the most striking beds in the large geometrical garden near here consisted of the old Verbena venosa, which stands the rain well, and Viola Perpetual Yellow—the best and most brilliant bedding Violet or small Pansy I have seen. Tropæolum Cooperi was here again in great force and beauty, and looked rich and healthy everywhere. The beds in this garden are mostly large and massive. The flowers are flanked by groups of shrubs and noble trees in all directions, while the Laurel terraces rise nobly into shelving hills of green. Associated with the scene now being described is a noble hardy Heath bed, a common thing in Scotland, and I marvel greatly that it is not also so in England. All the year round some of the

Heaths are in flower, and for beauty of habit and usefulness for cutting no plants can equal Heaths. Everybody likes them, and in colour of flower, homely aspect, and durability they have few equals. To show the style in which beds are furnished here I would notice one, a Rose bed. It is 155 feet by 30 feet, and is planted pinushion fashion thus: The soil is cushioned or covered over with common China Roses; standards are then regularly distributed amongst and over these, and two or three Gladioluses are, as a rule, tied to the stems of the latter, the whole being as beautiful as it is novel.

I fear, from what has been said, the gardens will seem a thing of patches and disjointed parts. They are, however, the very reverse of this. The genius of order, design, and unity of expression runs through them all like a golden thread, binding all the parts into one great whole. Standing or sitting in the centre of the group of gardens just described, and looking towards the castle that crowns the whole, the crown hardly seems high and lofty enough for its position. That, however, is but a momentary impression. From our chief stand-point the terrace, with the castle at our back, shutting the doors of the north wind, and the gardens lying far down below at our feet, we have such a scene as is rarely met with. Each garden is distinct in itself, and yet links its hand into and helps, as it were, the next, and so on throughout the whole series, which is spread over about fifty acres of ground. One of the great negative charms is, no boundary line is visible. I presume there are rabbit fences, but they are not seen. In all directions the flowers, shrubs, and choice trees dissolve, as it were, into the far-reaching woodlands.

Crossing the Marr burn by a rustic bridge, we reach the gardener's cottage, which in site, size, and convenience is a model of what a gardener's house should be. It commands, from the windows, a full view of the kitchen garden, six acres within the walls, and almost as much outside. Passing down from this cottage and crossing the carriage road, another large flower garden in the mixed style is reached. This occupies a large space outside the garden walls. There is here a border 500 feet long and 12 feet wide, devoted to a rich collection of herbaceous plants, all correctly labelled. Roses, Phloxes, Stocks, Pentstemons, Hollyhocks, Annuals, Grasses, Everlastings, Zinnias, Asters, hardy and tender Succulents, and bedding plants of all kinds, are grown here by the thousand, and massed both for effect and for furnishing and for edgings when wanted elsewhere. Amongst the Succulents the following seemed to be favourites, viz., *Sempervivum californicum*, *montanum*, *globiferum*; *Saxifraga rivularis*, *longifolia*, *hirta*, *pectinata*, *cristata*; *Sedum hispanicum*, *Fabaria* (spectabile) immense quantities, rnpestre, glaucum, *sempervirens*, and *cordifolium majus*. Tender Succulents may also be seen here in great variety, and on a border against the outer wall of the kitchen garden immense collections of Pentstemons and Phloxes are grown. The newer kinds of *Clematis* seemed wonderfully at home here—*Jackmanii*, *violacea*, and many others covering large spaces, and clambering over the summit of the lofty garden walls laden with flowers.

D. T. FISH.

**The London Squares.**—Permit me to suggest a very unpretending means of benefiting the poor at very trifling cost to the rich. I like to know that I am not singular in regretting that when this end of London is absolutely deserted at the close of the season, our Square-gardens should remain inaccessible to our neighbours, especially those who inhabit the narrow streets and crowded houses close by. I regret this, especially with reference to the children—many of whom may scarcely have seen the face of the country, and would be so much better and happier for even the smallest approach to it—so much safer than playing about on steps and curb-stones. I will anticipate objections on the score of abuse; though as we are not beginning to find that the flowers in Hyde-park and Battersea Gardens may now bloom untouched? and as to lawns and gravel walks, should they suffer in the course of the autumn, this would but be an anticipation of the ravages of winter. I am aware how much has been done lately for the people in this direction, but we have not yet done enough. The recent noble grant of Ebury-square for garden ground is an immense boon, small as is the area, and unlike a garden yet; but its value will be immeasurably enhanced should it lead the way to other kindred privileges, as indicated.—*S. E.*

## THE FLOWER GARDEN.

### HARDY FOREIGN FERNS.

**Oncoclea sensibilis.**—This is a grand plant for the out-door fernery. It has been in cultivation upwards of a hundred and fifty years, and yet how few know it. It is a deciduous Fern, producing broad, subpinnatifid, sterile fronds, the segments of which are entire at the margins and blunt at the points; they vary in height from about 1 to 2 feet, and their colour is bright pale green; the fertile fronds are about the same height, but differ wholly in every other respect. Instead of being very broad, they are much contracted, and instead of being subpinnatifid, they are bipinnate, having their segments rolled inwards, and thus forming, upon the upper portion of the frond, a berry-like spike. *O. sensibilis* is an extremely ornamental Fern, and one which is wholly distinct from any other in cultivation. It is a native of North America.

**Onychium japonicum.**—This elegant Japanese Fern is frequently grown in the greenhouse, and even in the stove. In most situations it is, however, perfectly hardy, but in severe winters some dead fronds of the common Brake may be thrown over it. The fronds are very finely divided, the segments being linear and of an intense dark green; the fronds vary from 1 to 2 feet in height, and are very useful for bouquet-making, or for placing loosely in vases with cut flowers.

**Osmunda cinnamomea.**—*Osmundas* belong to what are styled flowering Ferns, and this differs from most of the others, inasmuch as the fruiting fronds are wholly contracted, giving it a distinct and peculiar appearance. The barren or sterile fronds are bipinnate, slightly drooping, and glaucous green, the fertile ones are erect, and are produced from the centre of the plant. It is a deciduous kind, very widely distributed over the surface of the globe, having been found in both the East and West Indies, Mexico, and North America.

**O. cinnamomea angustata.**—This differs from the normal form in having rather more erect fronds, which are also narrower and smaller. It is a native of Canada.

**O. interrupta.**—This is a deciduous species, in which the fronds are bipinnate or twice divided, and vivid green, attaining a height of from 2 to 3 feet. When fertile, some two or three pairs of pinnae in the centre of the frond become contracted and sporangiferous—a circumstance which has given rise to the specific name. This noble species is abundantly distributed throughout the United States and Canada.

**O. gracilis.**—This is also a native of Canada, and somewhat resembles a dwarf form of our native Royal Fern; the fronds are about 2 feet high; they have blunt oblong pinnae, and bear upon the apex contracted sporangiferous segments.

**O. spectabilis.**—This is a slender form of our native species; its fronds are smaller than those of the Royal Ferns, and the young ones always come up reddish purple, which is its distinguishing feature. It is a native of North America.

**Platyloma rotundifolium.**—This is not everywhere hardy, but it is so distinct and handsome that it is worth a little extra trouble to include it amongst hardy kinds. The fronds are spreading, about 1½ foot long, pinnate, and the pinnae, which are nearly round, are intensely dark green. It is a native of New Zealand.

**Polypodium hexagonopterum.**—This most elegant North American species bears fronds from 12 to 18 inches high, bipinnatifid, triangular in outline, and deep green. It is deciduous and a splendid object in the out-door fernery.

**Pteris cretica albo-lineata.**—This originally came to us from Java, but it is also found plentifully in Japan. I have found it to be perfectly hardy in the neighbourhood of London. It is a dwarf compact-growing plant, the fronds of which are pinnate, erect, with long bright green pinnae, ornamented with a pure white band along the centre of each pinna. It is evergreen, and should be in every collection.

**Pteris scaberula.**—This is a dwarf, creeping, evergreen species, which no Fern grower should be without; the fronds are lanceolate, about 12 or 18 inches long, cut up into very fine and delicate segments of a bright light green colour. It is hardy in most places, but should receive a little protection during severe weather.

**Struthiopteris germanica.**—This species, which grows wild in Germany, attains a height of about 2 feet; its sterile fronds are pale green and pinnate, broad, and beautifully arched; the fertile ones are much narrower and erect. They all rise inside the barren ones, and form a beautiful crown, set off by the spreading green pinnae of the others.

**S. pennsylvanica.**—This is by some considered to be a variety of the preceding, but as it is very distinct in aspect, it matters little whether it be a species or variety. In general outline it resembles

*S. germanica*, but it is more erect in habit, and grows much larger. It is a native of North America.

*S. japonica*.—This Japanese species is of somewhat recent introduction, and is apparently a dwarfier and more massive plant than either of the preceding; its barren fronds are pinnate, broad-spreading, and dark green; like its congeners it produces its fruiting fronds in the centre, and these are also much contracted.

*Anchistea virginica*.—This is a noble North American species, nearly related to *Woodwardia*; it forms an underground creeping stem, from which the fronds rise to the height of about 2 feet. They are broad, bipinnatifid, and pale green, ornamented with a peculiarly-arranged copious dark brown sori.

*Lorinseria areolata*.—This is nearly allied to the last-named plant, and, like it, is a native of North America. Its fronds arise from an underground rhizome, and seldom exceed 12 or 18 inches in height; they are sub-pinnate, with broad light green serrated pinnae; the fertile ones are much contracted and erect. It succeeds best in moist situations.

*Sitobium punctilobulum*.—This beautiful light and graceful plant produces fronds from 18 inches to 2 feet high; they are sub-tripinnate, the pinnae being finely divided, and pale green, while the stipes are light brown. It is a charming plant for rock-work. It is a native of North America.

*Camptosorus rhizophyllus* (the Walking Fern).—This highly interesting little Fern well deserves a place in our hardy Ferneries.—*Villa Gardener*. [A good idea of the singular appearance of the Walking Fern may be gleaned from the accompanying illustration, and account of it which we subjoin.]

WALKING FERN.

This singular and interesting little Fern is found in rocky woods in North America. It grows in the almost soilless niches of rocks, or gets a foothold on their naked inequalities. It is quite rare, and during several years my searches in the woods were unrewarded with a sight of its odd little leaves, till one day, ascending a low mountain in a quiet, mossy slope of gray rock, far above my head, a company of these little "Walkers" was discovered. The frond is simple reticulate, veined in the midst, and forked only at the margin. It is undivided, lance-shaped, with heart-shaped lobes at the base, and the apex attenuated into a long, slender acumination, that often bends over backward and takes root, giving rise to a new plant. Thus, the Fern takes one step a year. I have never seen one that had stepped twice. The faint dots are variously shaped, and scattered without order on the transverse veins, slanting and at various angles, often in pairs and facing each other, looking something "like writing;" hence its Greek name—*Antigramma rhizophyllea* of Presl. It can be cultivated in the same manner as other hardy Ferns, always taking care to give it a soil and atmosphere as near like that in which it grows naturally as possible, remembering it needs little light, much water, and to be let alone.—*American Agriculturist*.

[Mr. Backhouse, of York, informs us that he found this singular little Fern grow quite freely in narrow well-drained fissures of rock-work; but that as sure as there was a slug in the garden its young fronds would disappear.]

**Variation in Roses.**—The following interesting communication of M. Du Brenil to the *Gardini*, an Italian Horticultural Journal, is worthy of some attention:—"In July 1867 I paid a visit

to the garden of a judge at Baguères-de-Bigorre. He showed me several standard Roses, and among them a *Géant des Batailles*, some of the dark red flowers of which were marked with numerous spots of a pale rose colour. I remarked the same peculiarity in varieties with paler flowers, such as *General Jacqueminot*. All were in a very fine condition of growth and presented all the other characteristics peculiar to the different varieties. Monsieur X. assured me that this variegation was permanent, and that it was capable of being perpetuated by budding. On inquiring what could have given rise to this singularity, he informed me that having been obliged, when budding a few years previously, for want of better, to use some buds which had no apparent eyes; these nevertheless sprouted and produced flowers, all of which exhibited the peculiarity described, and which he attributed to the imperfect conformation of the buds which he had employed. He then repeated the experiment with the same result, and he now produces this variegation at pleasure by operating in the manner described."

NOTES AND QUESTIONS ON THE FLOWER GARDEN.

**Bidens atrosanguinea.**—Your correspondent, Mr. Donald (p. 110), speaks of the beauty and usefulness of this plant, and he is right. He says the roots are very like those of a Dahlia. By some botanists this plant is classed with the Dahlias under the name of *D. Zimapani*. Let me advise Mr. Donald, by way of companionship to his favourite, to grow *Dahlia glabrata* with mauve or white, *D. coccinea* with scarlet, and *D. Cervantesi* with orange-red single flowers. If he does, I am sure he will be pleased.—H. HARRUP CREWE, *The Rectory, Drayton-Beauchamp, Tring*. [Mr. Thompson, of Ipswich, states that it is properly, according to Sir J. W. Hooker, a *Cosmos*, and says that he sells it as such. It is also sold as *Dahlia mexicana* and *Dahlia atrosanguinea*.]

***Enothera marginata*.**—The plant which has been grown as *Enothera marginata* for the last few years, and the beauty of which it is impossible to praise too highly, is not the true *E. marginata*, but *E. eximia*. The true *E. marginata* is only very recently introduced. It is also a very beautiful but quite distinct species.—H. HARRUP CREWE, *The Rectory, Drayton-Beauchamp, Tring*.

**Violets.**—I had the good fortune last spring to stumble across two distinct forms of British *Viola*. One is *Viola Riviniana alba*, white as snow, the other is *V. hirta rosea*. I shall be curious to know whether these two forms reproduce themselves from seeds which I have sown, and expect

shortly to see. *Viola Riviniana alba* I found at Riddlesdown, and of *V. hirta rosea* I found a small colony of five plants at Crome Hurst. I have other curious British *Violets*, but the two above mentioned are very distinct, and I have little doubt will come true from seeds.—W. ELLIOTT, *Berkhamstead*.

**Blue Hydrangeas.**—M. J. Duronnet, in a letter to the *Revue Horticole*, states that he knows from experience that the admixture of coal cinders with the soil in which Hydrangeas are grown is sufficient to cause the production of blue flowers on these plants.

**Amarantus salicifolius in America.**—With us during the past summer this has been all that was promised, and even more; the plants grew very rapidly, and attained a height of nearly eight feet, sometimes even ten. The habit of the plant is very graceful resembling that of a Weeping Willow, on which account it has obtained the name of "Willow-Leaved Amaranth." The colour of the leaves is a bronze green, which changes to a bright carmine, about the middle of August, on all the ends of the branches, making plumes of such dazzling beauty as to be truly magnificent.—FRANK ROMER, *Tarrytown, State of New York*.

**Parochetis communis.**—Having heard complaints from gardeners about losing this beautiful creeping plant, and wondering at the cause of its sudden disappearance, they may be interested to know that mice are its greatest enemies. I lately purchased a nice strong plant of it in bloom, and being about to make up a jardiniere for the boudoir, I thought how pretty it would look in it, with its elegant blue flowers hanging over the side; but imagine my disappointment upon reaching it from the stage to find that not a particle of the plant was to be seen. There was, however, every evidence, to my mortification, of the mice having regaled themselves upon it.—C. COOMBS.

**Hydrangea paniculata grandiflora.**—This is a handsome shrubby plant, from 20 to over 30 inches high, introduced from Japan about the year 1864 by M. Siebold. The flowers, which are produced in a dense, handsome panicle, are at first white, and afterwards pass through various shades of rose-colour to a violet-red, changing at last to a greenish brown, so that their appearance varies from day to day. It is exceedingly ornamental, thrives in almost any soil or position, is quite hardy, and can be propagated with the greatest facility from cuttings.

Walking Fern.

## THE FRUIT GARDEN.

### HARDY FRUITS.

#### THE GOOD AND THE BAD.

WE are about to point out the kinds of fruits that are best for cultivation; but, first of all, it must be understood that we have no intention of enumerating all the good ones, nor even all the best. We purpose to mention only a certain number of them which have a good flavour and reasonable size, are good bearers, and of comparatively easy culture; which may be relied on with perfect confidence, without fear of disappointment or regret, trustworthy subjects which we have ourselves proved; few in number, but sure, and giving perfect satisfaction in every stage of their cultivation. This selection is not so strict and exclusive as to condemn all others, some of which may, perhaps, be quite as good, but we must draw a line somewhere, and we shall endeavour to do so as discreetly as possible. We certainly grow good fruits, we even possess a great number of them. Horticultural societies, by means of their exhibitions and numerous fruit prizes, horticultural journals by their descriptions and announcements, do all they can to make them known; but still all this is done within the limits of a certain circle, and when improvements come, they come slowly. Who knows the good kinds of fruits? Nurserymen, pomologists, an amateur here and there, and that is all. They are met with in the gardens and on the tables of some favoured individuals, or, perchance, in the window of a restaurant. Elsewhere they are not to be had, and no doubt many persons of great wealth would be very much astonished if told that, in the midst of a luxury of which no detail appears to them to be wanting, there are, nevertheless, some princely enjoyments which escape them, and of which they never taste. It has been said that bad acquaintances are more easily made than good ones, and this applies in some degree to bad fruits also. The few favoured individuals, the connoisseurs of whom we have spoken, are not troubled by them, but the rest of the public, the townsman who buys in the market or in the street, the countryman who goes to his orchard for his dessert, the tradesman at his own house, the artisan in the workshop, or the boy at school, what good fruits are they acquainted with beyond five or six varieties? And yet we have good fruits. We cultivate the trees which produce them, we strive to make them known, as we are doing now. But then there are others which already occupy the place which these should have, there are fields full of large trees bearing fruit without name and without value, and people will not sacrifice these—first, because they would have to part with what they have; secondly, because they would have to buy what they have not; and, thirdly and chiefly, because they would have to wait. All this is very true in its way, and there, we confess, lies the difficulty. Nevertheless we must endeavour to gain our object, even though we have to struggle lustily for it, and pile admonition upon admonition, and pamphlet upon pamphlet—in a word we must make converts to our way of thinking.

We do not think that cultivators who for many a long year have lived side by side with their old and bad trees, are going all at once to root up these old companions of theirs, and replace them by the trees recommended. It is not from the growers that we must expect the first step in the path of progress, but from the consumers. When the purchaser knows that instead of bad or inferior fruits it will be possible for him to obtain for the same price others of excellent quality, he will ask for these. It is the demand which governs trade. Let a landowner cease growing this or that kind of tree and send an order for another kind. Soon the intelligent nurseryman sets about grafting a plentiful supply of the kind in request; the cultivator takes his fruit to market, those fruits that used to sell so well; but since he was there last the public taste has changed, no one will have them, and his cart returns as full as when it set out. This affords grounds for reflection; tastes change and we must follow them. And that is how, gradually and little by little, the culture of fruit trees will be modified amongst us; all depends on the public, on you, on us, on everybody; all we have to do is not to allow ourselves to be led by the seller, but to lead and direct him; it ought to be known that there are in cultivation a much greater number of fruits than are necessary to supply at almost all seasons an excellent dessert, and that if we do not, some day or other, see them on everybody's table, it is because our cultivators, from carelessness or ignorance, either do not wish or do not know how to do better.

General advice respecting each of the kinds of fruit which we shall consider—Pears, Apples, Peaches, Apricots, Plums, Cherries, Grapes, &c., down to Strawberries—an ample and conscientious selection of varieties, with the best mode of culture when that is necessary—all in the order of ripening, with the view of showing the resonances of each month; some brief reflections, with which we shall commence, on the preparation of the ground, and the planting of the trees, is what we intend to give.

#### PREPARATION OF THE GROUND.

Whoever wishes to plant successfully must open his purse generously. There is a liberality which enriches, just as there is a parsimony which ruins. The preparation of the ground and the planting of the trees are the touch-stone of a judicious outlay. If, then, you wish to make a fruit garden, and to receive from it the greatest possible return, do not forget that the results will always be in direct proportion to the amount of well-expended outlay which you are willing to make upon it. Should a certain amount be beyond your means, do not go so far, that would simply be an act of folly; take your time, distribute your expenses over several years, do not plant all your ground at once, leave a part of it at rest, the half if necessary; it is better to have a small portion in a good condition than ever so large an extent in a bad one; this is the verdict of experience.

Trees are good feeders, and they must have good food, that is, manure. The colder and moister the soil is, the better must the quality of the manure be; and sheep and goats supply the best kind for warming the soil. Large towns do not always know what to do with the sweepings of their streets; these are just the thing for a cold, damp soil, and will afterwards return to them agreeably in the shape of good fruits for their markets and tables. If the land is warm, on the contrary, use cow-manure, which is cool and refreshing to such a soil. Moreover, all kinds of manure furnished by sheep, cows, horses, sweepings, &c., well mixed together, will suit any soil. Having provided the manure, the next thing is to put it in the ground, which, for this purpose, must be trenched up to a depth which will vary according to that of the stratum of good arable soil which covers it; this is usually from 2 to 3½ feet. Let us suppose it to be 3½ feet. The trench, which must be at least 7 feet wide, having been first marked out, we begin at one end, and there open a cut 2½ feet deep; the soil taken out is carried to the other end of the trench, where we shall want it by-and-by; we then break up the bottom of the cut to the depth of the spade, and place in it a layer of manure, and on that 10 inches deep of soil, then another layer of manure and another of soil, and a third layer of each, always 10 inches thick. We then proceed to the next cut and act in the same manner. It is needless to remark that, as we work going backwards, the soil which is behind us is that which is put on the top of the cuts in succession, so that when we come to the end of the trench, the soil which was carried there at the commencement of the operation serves to finish it. The work is then done, and we have a piece of ground well dug, well manured, and in perfect condition for planting. We cannot, unfortunately, always go so deep as 3½ feet, because at that depth we often meet with clay or gravel, which are by no means good things for our fruit trees, and it will be best not to disturb them. If, then, we cannot go deeper than 2½ feet, we must reduce the depth of our layers of manure and soil to 8 inches, but in other respects act as before. But suppose we cannot go so deep as even 2½ feet. Well—we'll not talk of impossibilities; let us have two layers of soil and manure instead of three. There is, however, a way of remedying this last-named inconvenience, and one to which necessity may compel us to have recourse when the subsoil is bad, and also when the layer of arable soil is not even 2 feet deep; we then make use of an expedient. As there is no good soil below, we must put some above; if we have not got depth in one direction, we must create it, so to speak, in another, by carrying fresh soil and putting it on the top, and even if we do not in this way secure the respectable depth of 3½ feet, we may at least obtain a depth sufficient to answer our purpose. The work is not to be done at all times and seasons; we must seize the happy moment when the soil is in suitable condition, and especially when it is not too wet. Sometimes the soil is very wet; this is unfortunate, for whatever is planted in it is sure to suffer; but there is a remedy for this also, in restoring the ground to a sound and wholesome condition. We of course assume that the ground is properly drained. Good drainage is a very important matter to persons living in a country like ours; indeed, it is found to be so in all countries. "Do not expect fruit in a frog-pond," said an American. Drain well, above all things, except your soil is perfectly drained naturally.

F. JAMIN.

#### FOOD VALUE OF FRUITS.

BY C. D. HUNTER, F.C.S.

COMPARATIVELY little attention has been devoted in this country to the chemistry of the fruits. So great is our ignorance on this subject that writers on food topics generally say as little about them as possible. And what they do say is generally a simple recast in their own phraseology of some ancient statements about the healthfulness and wateriness of fruits. In Germany, where chemistry has been long naturalised, and where numerous experimental agricultural

statistics exist, aided by the Government, much has been done in the scientific examination of plants, &c. We, in consequence, owe to Germany much of our knowledge about agriculture and its kindred sciences. The authorities quoted in scientific works and lectures on these subjects are chiefly German. Liebig and Fresenius are familiar examples of this, but their names are legion in every department of science and art. The following table of the "composition of fruits" is condensed from a list of fifty-one analyses made by the celebrated chemist Fresenius, and reprinted in Johnson's "How Crops Grow," from the "Ann. Chem. u. Pharm." ci., p. 219. The original gives the result of each analysis separately, a minuteness of detail necessary in a purely scientific paper, but very inconvenient for general purposes. These have been averaged wherever the nature of the analysis permitted of so doing, but as in the original they are not all given in equal detail, several had to be omitted. The Riesling Grape, the first on the list, is an example of an analysis imperfect in detail, no determination having been made of the albumenoids, &c., and but for its position as first in the scale this analysis would have been omitted. The fruits are arranged in the table according to the percentage of soluble matter. This, other things being equal, is a fair measure of their comparative values for food. The percentage of water does not show this value so well because of the great difference between the fruits in the percentages of insoluble matters. This latter item consists chiefly of seeds and skins, with a small quantity of insoluble cellulose and pectose, the latter rarely amounting to one-fifth. The sugar in the first column includes both saccharose and fructose. The acid in the second column is expressed as hydrated malic acid.

COMPOSITION OF FRUITS.

Number of Analyses.	KINDS OF FRUIT.	SOLUBLE MATTERS.						Insoluble matters.	Water.
		Sugar.	Free Acid.	Albumenoids.	Pectine bodies, Gum & Organic Acids in Combination.	Soluble Ash ingredients.	Total soluble matters.		
2	Grapes, Riesling ...	14.33	.60	—	—	—	18.70	—	75.21

1	Pears, large Holland ...	1.57	.67	.62	8.04	.67	11.83	7.49	80.77
1	Apricots, large ...	1.34	.84	.61	7.69	.78	11.17	5.34	83.48
6	Gooseberries ...	7.12	1.43	.42	1.18	.38	10.53	3.42	86.21
6	Currants ...	6.38	2.15	.50	.15	.59	9.77	2.42	84.81
1	Strawberries, Ananas ...	7.57	1.13	.36	.56	.86	9.33	13.12	77.55
1	Whortleberries ...	5.78	1.34	.79	.42	.52	8.48	4.52	87.00
1	Plums, blue and black ...	2.13	1.39	.45	4.08	.32	8.18	4.52	87.00
1	Raspberries, garden ...	4.29	1.23	.69	1.58	.43	8.05	4.52	87.37
1	Blackberries ...	4.41	1.19	.57	1.44	.41	8.00	5.59	84.41
1	Raspberries, wild ...	3.69	1.98	.53	1.11	.27	7.51	8.64	83.86
2	Strawberries, wild ...	3.99	1.49	.59	.10	.67	6.75	6.19	87.15

The above shows strikingly how inaccurate is the common notion about fruits. It also shows that the proportion of solids is much larger than it is generally stated to be in the brief and superficial sentences devoted to this subject in many works on food. The improvement in the nutritive value of fruits effected by cultivation is strikingly seen on comparing the composition of the garden Strawberries and Raspberries with that of the wild varieties. The increase of the soluble or easily digestible matters is very considerable, amounting in the case of the Strawberry to nearly fifty per cent. In the case of the Raspberry comparison is less easy, the garden specimens containing less solid matter; glancing, however, at the insoluble matters, it will be seen that these have diminished nearly one-half in the cultivated variety.

Judged by the old standard of the amounts of nitrogenous, albumenous, or so-called flesh-forming constituents, fruits occupy a very low position indeed. But this now disproved standard condemned also the meats and oily substances found by cattle feeders to be so superior for feeding purposes to any of the so-called flesh formers. Judged by the more rational view now entertained by our best chemists and physiologists, that the true measure of nutritive value is the force or potential energy of the substance, fruits occupy relatively a much higher position. In Dr. Frankland's Royal Institution lectures on the source of muscular power, he gives a table showing the actual energies developed by various foods when oxidised in the body. A sample of Apples containing the

same proportion of solids as the Reinettes in the foregoing table bore the following relation to other foods, taking 1 lb. of Wheat flour as a standard.

	lbs. ozs.	Ground rice	lbs. ozs.	Milk	lbs. ozs.
Flour ...	... 1 0	... 1 0 1/2	... 1 11	... 6 1 1/2	... 6 1 1/2
Apples ...	... 5 15 1/2	Hard boiled eggs	... 1 12 1/2	White of egg	... 6 16 1/2
Veal, lean ...	... 3 4 1/2	Bread ...	... 1 12 1/2	Carrots ...	... 7 6 1/2
Beef, lean ...	... 2 11	Potatoes ...	... 3 12 1/2	Cabbages ...	... 9 3 1/2

Grapes would probably stand about 5 lbs. 2 ozs., and the other fruits in proportion to their quantity of solid matters. It must always, however, be borne in mind that all comparisons of the nutritive value of foods are only reliable in so far as the foods compared are equally digestible. Of invalids it may be said that what is food to one is poison to another, and with them each case has a law to itself. With the ordinarily healthy the results are more uniform, but unfortunately we know more of the relative digestibility of foods for cattle than of those for men. Experiment has, however, shown that nearly one-half of our ordinary daily food escapes complete digestion and assimilation. In the light of this fact the fruits occupy a very favourable position, the great majority of them showing a very high proportion of soluble matters. This in the more common fruits ranges from two-thirds to five-sixths of the total solids, and must in comparison with many foods more than double their nutritive value. This also partly explains the value to invalids of such fruits as Grapes and Strawberries, both of which contain relatively but a small proportion of insoluble matters.

The term "anti-scorbutic drinks" shows in what high estimation fruits have always been held as health preserving agents. And now that more accurate analyses, and a better understanding of the nature and values of foods, show them also to be highly nutritious, it is evident that they should be used as foods. Fruits, from a false idea of their nature, have too frequently been used as drinks and taken at improper times. They have, in consequence, received a bad name, and apprehensive mothers warn their children against fruit; visions of diarrhoea, cholera, &c., being held up as bogies to enforce obedience; but let them give extract of beef or any other of the supposed concentrated nutritious flesh foods, and watch the result. They will not have long to wait before the same stomach ailments begin to show themselves, and that in forms more dangerous than ever followed the use of ripe fruit at equally unseasonable hours. Fruit should be used as part of a meal. With children and healthy adults, just before breakfast and dinner are the best times. Invalids will find it safer, especially with juicy fruits, to take it about the middle of the meal, other dishes preceding and succeeding it. This refers chiefly to uncooked fruit. When cooked and served hot, fruit may be safely taken at any period of the meal. Invalids will also generally find the more acid fruits less digestible, and especially so when preceded in the same meal by Potatoes. Fruits, especially when not quite ripe, are generally rendered more digestible by cooking. Stewing is the general, and a good method, but roasting is preferable. This may be done in an oven, or before an open fire. Apples tightly wrapped in paper are easily and pleasantly roasted before the parlour fire. Done in this manner they will generally be found to require little or no sugar, a decided advantage with invalids.

Unripe fruits should not be eaten, many of the acids found in the green fruits being poisonous. Unfortunately no analysis of green fruits is at present available. The following, however, shows the changes which takes place in a year from ripeness to mellowness, and finally to decay:—

PEARS.

	Ripe and Fresh.	Kept till Mellow.	Kept till Brown.
Resinous colouring matter...	0.08	0.01	0.04
Sugar .....	6.15	11.52	8.77
Gum .....	3.17	2.07	2.62
Lignine .....	3.80	2.19	1.85
Albumine .....	0.08	0.21	0.23
Malic Acid.....	0.11	0.08	0.61
Lime .....	0.05	0.04	—
Water .....	86.28	83.88	62.72
	100.00	100.00	76.84

It will be noticed that as the Pear mellowes the sugar increases in amount chiefly at the expense of the gum and indigestible lignine. The rotting Pear again shows a decrease in all the more important constituents, the sugar has in part fermented, and gone off as carbonic acid and moisture, there being a loss in weight of about 23 per cent. A sour acid of decay has also been generated called metaplectic acid, which is in the table incorrectly entered as malic acid. Much more of interest might be added, but enough has been said to show that the more accurate and extensive our knowledge of food and its properties becomes, the more highly will we value the fruits as healthful and nutritious foods.—*Dietetic Reformer.*

## A REMARKABLE BATCH OF SEEDLING PEARS.

PRESIDENT BARRY made an interesting report of the result of an experiment in growing seedling Pears in California, at the late meeting of the Western New York Horticultural Society held at Geneva. "In the month of November last, I received twenty-six varieties of seedling Pears raised by Mr. Bernard S. Fox of San José. Their appearance astonished me. Many of them were so much like some of our old well-known sorts that I half suspected my friend Fox of playing a joke on me. There were Bloodgood, Seckel, Lawrence, Winter Nelis, Beurré Clairgeau, Beurré Bosc, Easter Beurré, Duchesse d'Angoulême, Beurré Superfin, Glou Moreau, and others. Some friends, very good judges, to whom I sent specimens, had the same doubt in regard to their being seedlings. When I began to examine them closely and cut them, I found they were distinct from the sorts they resembled, and were positively new. I then wrote to Mr. Fox for some account of their origin, and he answered that they all sprung from the seed of the Belle Lucrative, sown in 1863, and had fruited in the rows where they had first grown. Some bore the fifth year, and in the sixth over 200 bore fruit. One-fourth of the trees have not yet fruited, and for five years to come new fruit may be expected. Many of these varieties are fully equal in size and beauty to our best Pears, and many have the advantage of being quite late. Generally speaking, they are deficient in vinous flavour, like the Easter Beurré and others of that class. Only one or two were vinous; but some were justly entitled to rank among our best kinds. A few of the largest appeared to be of inferior quality; one specimen of these, resembling Nouveau Poiteau in 1871, weighed two and a half pounds. This is, beyond doubt, the most remarkable instance of success in raising seedling Pears on record. And the fact that all are from seed of Belle Lucrative, and none like that variety, but like all the others growing around, is both curious and interesting, showing that the mother plant did not affect the character of the varieties. This might not have been the case had some other varieties supplied the seed. Much of this success is, no doubt, due to the peculiar climate of California. The early age at which these trees began to bear, even in the seed-bed, seems strange."

N. Y.

**The Jardin des Plantes Collection of Fruit Trees.**—In his last work, M. Decaisne cites the instructions under which the collection of fruit-trees in the Paris *Jardin des Plantes* was constituted. The professor of culture was charged with its management, and was directed to bring together all the known varieties, with all their names, "afin d'établir une uniformité de nomenclature nécessaire pour toutes les parties de la République." This is a decree of the National Convention, June 10, 1793. The collection which Decaisne has so diligently and acutely studied actually dates from the year 1792, when the fruit-garden of the Chartreux of Paris was broken up, and two trees of each variety transported to the *Jardin des Plantes*. In 1793 it contained 185 varieties. In 1824, when Thouin died, there were in it 265 varieties of Pears alone; it has now more than 1,400 varieties of this fruit. It is interesting and important to know that the collection still preserves the greater portion of the very types described a century ago by Duhamel.

## NOTES AND QUESTIONS ON THE FRUIT GARDEN.

**"Sweet" Apples.**—Will any of your readers kindly inform me what the American papers mean by "Sweet" Apples, which they seem to distinguish as a peculiar class. Also if they are known in this country, and what are the best kinds?—W. R. V.

**Moss on Fruit Trees.**—The *American Horticulturist* says, nothing is better for removing this than carbolic soap and lye. Make common lye of wood-ashes, not strong, and add half a pound of carbolic soap to a three-gallon pail of boiling lye. Apply hot with a swab to old trees. It has been used with entire success on Apple, Pear, Peach, and Cherry trees, destroying every particle of moss it touches.

**Imported Grapes.**—The best source of supply at present is Almeria, in Spain, where the white hard-fleshed Grape now visible at every fruiterer's is grown. It is much easier transported than one would infer from its delicate appearance and perishable nature. Buried in sawdust it can stand a seven days' voyage with very little risk. The principal difficulty is to obtain the sawdust clean enough. Almeria itself cannot furnish sufficient to pack the thousands of 50 lb. barrels which are shipped weekly. Very often a cargo has to be sent out from England, and cork sawdust, which is reputed in the trade to be the best preservative, has to be brought from even greater distances. Hambrough Black Grapes are imported in a similar way, but are much less popular than the Almerias.

**A Fruit Farm.**—A correspondent of the *American Rural Home*, who has visited the farm of Mr. T. G. Yeomans, of Walworth, Wayne county, says that Mr. Y. has 14,000 fruit trees in bearing, 4,000 of these being Duchesse d'Angoulême Pears, and sixty acres being occupied by Baldwin Apples. The trees of the latter he describes as having "straight, smooth, healthy looking bodies, about 1 foot in diameter, and all branching to about 6 feet from the ground." The Duchesse Pear trees are beautiful and productive, and free from disease. In all, Mr. Yeomans has about 100 acres of land, the larger part of it being devoted to the nursery business.

## THE ARBORETUM.

## TREES OF THE ROCKY MOUNTAINS.

"Why, there ain't no Rocky Mountains. I've just come across the whole of the United States territory, from San Francisco to New York, right through by the Pacific Railway, and I tell you, Sir, that there ain't no Rocky Mountains—no way you can fix it. There's the coast range, and the Nevada Mountains; them air some mountains, but for Rocky Mountains I calculate they don't exist." Such was the answer we received a few weeks ago to an enquiry which we put to a new arrival from the other side, and the answer was, so far as the point to which the speaker's knowledge extended, perfectly true. For days the railway seems to be speeding along on a dead level as it approaches the line of the Rocky Mountains, and the slope is so gradual that it is only when we are told that we are descending the other side that our expectations of magnificent scenery, lofty peaks, and tremendous passes are banished from our mind, and we recognise the fact that at the point where the railway crosses the Rocky Mountains the summit is reached by a very gradual slope on each side. For a long space on each side it is apparently one continuous and boundless prairie, traversed from time to time by rivers. At this season of the year it is swept by the keenest and most merciless winds, laden with drift and snow, defying all the efforts of American ingenuity to prevent the railway passengers being chilled to the bone in the cars. How great the contrast at other seasons! In autumn, the deliciously mild and at the same time exhilarating air, charged with the aromatic odours of the Artemisia and what is almost an Alpine herbage, is described as so enjoyable that the passenger sits inhaling it from morning to night, unwearied by the sameness of the scenery, and feeling mere existence in such a climate to be in itself happiness.

Very different is the aspect of the Rocky Mountains in other parts of the range. There we find lofty peaks, precipitous ravines, and pathless forests. Such is the scene depicted in the accompanying woodcut, taken from a region further to the south than that to which we have just alluded. Different kinds of trees in different localities give a different stamp to the character of the scene. Near the summit will be found *Pinus flexilis* (a kind of Cembra) transformed from a tree into a sprawling shrub no higher than a yard above the ground, from inability to face the blast; but with old and gnarled branches crawling along the ground and matted so thickly that a man can almost walk over its top. With much the same habit, occurs in similar localities, the botanically curious *Pinus aristata*, also a five-leaved Pine, but with the leaves so short, thick, blunt, and curled up as to look more like the foliage of *Abies nobilis*.

Further down, clothing the slopes, will be found the widespread Douglas Fir, which is, no doubt, the tree which clothes the slopes represented in the accompanying woodcut; botanically the same as the Douglas Fir of Vancouver's Island, British Columbia, and California, but so different in aspect and quality that the practical man is apt to think that the botanist must be mistaken, and that after all there must be two species of Douglas Fir. From Vancouver's Island all along the Pacific slope down to Santa Barbara and Los Angeles, the Douglas Fir is met with, of that magnificent stature and possessing that unmatched timber that have made its name so famous. Stems of 200 or even of 300 feet high are the ordinary dimensions of the finer specimens; and wherever it occurs along that coast the timber is straight, elastic, tough, and without knots, so as to fit it admirably for masts and similar purposes. In the Rocky Mountains again, the Douglas Fir runs straight down far into Mexico; but it has lost its lofty character, 60 or 70 feet being its ordinary altitude, and 90 feet an extreme height. Its timber, too, instead of being tough and elastic, readily warps, and has ceased to be tenacious. The bracts of the scales of the cones of this Rocky Mountain and Mexican race seem also, as a whole, more projecting than in the coast kind. How far north this race extends in the Rocky Mountains, and whether its range unites with that of the coast in the north, we do not know, but there

TREE VEGETATION OF THE ROCKY MOUNTAINS.

is certainly an interruption at the plains through which the railway passes.

Further south, as the Rocky Mountains pass into the mother range (Sierra Madre) of the Mexican Mountains, other species of Pine and Fir vary the scenery. Nature has there been good to the aborigines who inhabited these lands before the advent of the white man. Including those of California, she supplied eight or nine different kinds of Pines with edible seeds, viz., *Pinus flexilis* above mentioned, *P. edulis*, *P. monophylla*, *P. Sabiniana*, and *P. Coulteri*, and the Sugar Pine, not to speak of the larger forms of *Pseudo-strobus* in Mexico, *P. Ayacahuite*, &c.

On the deciduous forest scenery of the Rocky Mountains our space will not allow us to enter. It may be sufficient to remind our readers that Oaks, Walnuts (or Hickory, as they are called in America), Chestnuts (Buckeyes), Poplars (Cotton-wood), &c., combine, with many others, to vary the charms of the wild scenery. A wide field lies open, too, for the explorer and botanical collector. For a country that has now been so much traversed, it is surprising how much that is new is discovered by every fresh visit of a scientific man, a fact which in itself shows that much more still remains to be discovered. A. M.

#### TREES WANTED IN THE BROAD THOROUGHFARES OF WESTERN LONDON.

The beautifying and softening effect of trees in connection with architecture is beginning to be freely admitted in theory; but the aversion to change which so strongly characterises the average British mind is by no means ready to put the theory in practice. For instance, a proposal to plant an avenue of trees along the Edgware Road from the Marble Arch to Maida Hill would, there can be little doubt, be strongly objected to, as an unnecessary and inexcusable innovation, by a very powerful, influential, and respectable section of the public. It cannot be urged that the thoroughfare is not sufficiently wide for the purpose; or, denied that a fine avenue of trees would make it a promenade almost as attractive as the Boulevard des Italiens by the time that the trees attained a tolerable size, and the present mean houses had given place to buildings of a higher class, as they are already in process of doing; yet the change would be stubbornly resisted as long as possible on half a score of more or less plausibly sounding pretences.

The call for trees along the Thames Embankment was long addressed to official ears in vain; the stone-deafness of the British official is indeed almost supernatural when "unheard-of" novelties are talked of; and the plantation of an avenue of trees in the centre of London no doubt appeared so preposterous when first suggested, that officialism, which is not in the habit of going out of its way to redress grievances, was perhaps justified in remaining deafly undisturbed in its undeviating equanimity till the call became too loud to be disregarded. When at last the official ear was opened, and the call no longer seemed to it so very absurd, it was determined, after a good deal of careful hesitation, to carry it into effect; but doing so was a much easier matter than planting Edgware Road would be. The embankment was altogether a novelty, one that had been long staunchly opposed; but being at last done, was found not to be so mischievous an innovation as the great and powerful party of jottrots had prophesied. And so, being a novelty, and a still uncompleted novelty, the unwonted introduction of an avenue of trees in a London thoroughfare was taken to by the public as part and parcel of a novelty which had not turned out by long odds so badly as was expected. Had the embankment remained unplanted for twenty years, the opposition to its plantation with an avenue of Oriental Planes would have been most obstinate, and might very possibly have triumphed.

One of the objections I have heard recently urged against the planting of trees in London is, that even if desirable, it would be useless to attempt it, inasmuch as they would not grow. Not on account of the smoke—that is an enemy to vegetation which it has been found that Oriental Planes and several other trees defy. No; it is a new difficulty, and one that has curiously enough been put forward during the present exceptionally wet season, namely, an absolute want of moisture. The main drainage and recent sewerage works of London have, it is suggested, so greatly exhausted the water-bearing strata of the Metropolis as to have a most injurious effect upon all kinds of vegetation within its circuit, and has already caused the gradual drying up of many of the ancient and celebrated wells of London. This objection to tree planting in London appears on the very face of it fanciful in the extreme, and should, at all events, be tested before being accepted as a *fait accompli*.

Whatever may be urged against such an "innovation" as planting trees in existing thoroughfares, even when sufficiently wide, none can be put forward against providing for noble avenues of trees in many of the great new roadways now forming in the suburbs. The greed of landowners and of lease-holding builders might surely curb itself a little, and, by giving another fifteen or twenty feet to the new roadways, provide ample space for the planting of avenues of trees of various kinds, as almost any kind would flourish freely in the comparatively open villa neighbourhoods. What charming suburbs we might have to this vast Babylon of bricks and mortar if this suggestion were attended to! Surrounding the mighty core of smoke-blackened brick, one might expect within a moderate period of time, to realise (climate allowed for) an embowered and leafy city such as the Marquis de Beauvoir, in his recent travels, describes Batavia to be—green and flowery throughout, with exuberant and beautiful vegetation. Nevertheless, such hopes may be utterly vain—there are so many opposing views and interests; those of the landowners, the builders, the district surveyors, and a large number of prejudiced people, who, having no love of trees, ignorantly deem their presence unhealthy. When London built his house in Porchester Terrace, Bayswater, he planted a Sumach at the edge of the pathway, opposite to his residence; but the unusual proceeding met with extremely prompt and triumphal opposition. The district surveyor complained of its being likely to shade the pathway, and keep it damp, and the neighbours declared that it would be very unpleasant to pass under the drip of its leaves in showery weather, and so the Sumach had to be rooted out, and its magnificent foliage was not allowed to gladden the eyes of poor London from his dining-room window, as he had looked forward to. It is gratifying to find, however, that other places are not so conservative as London in the matter of opposing the plantation of street and roadway trees; and that Brighton has recently taken the lead in the opposite direction, in a very decided manner, as briefly notified in a recent number of THE GARDEN. Trees were, in fact, much wanted to improve the somewhat blank and bare appearance of that magnificent watering place, though some opponents aver that they preferred Brighton as it was, especially late in the autumn, because there were no trees to look wretched as they lost their leaves. In spite of this view of the matter, two lines of fine young trees have just been planted on the outer skirts of the central pavement of the Steyne; and it is intended to plant two other lines inside the adjoining enclosures, to run parallel with those on the outside, so as to form an avenue from Castle Square to St. James's Street. It is perhaps doubtful whether trees will flourish on the Steyne itself, which is entirely open to the sea, and exposed to all the violence of the south-west gales. But that those in the streets, which are protected by the Cliff houses, will do well there can be little doubt, and they will supply to Brighton a feature that in a picturesque point of view was badly wanted; its excessive bareness of any kind of foliage being remarked as a disagreeable characteristic by a very numerous class of visitors. The *Builder*, in referring to the planting of these trees in Brighton, observes that, in all probability, the eastern road will be planted in like manner from the College to Kemp Town. It is to be hoped that in some of the broad thoroughfares of western London, this planting of street trees may ere long be imitated, for it is truly surprising that so little has been done in that way, and that obstructive opposition has been up to the present time so successful. H. X. H.

**Measuring the Heights of Trees.**—In his tale of "Monsieur Violet," Captain Maryatt tells us, as an instance of the great aptitude for applying simple rules possessed by the Shoshone Indians, that when they desired to measure the height of a tree at any time when its shadow was cast on the ground, they used to place a stick of a given length into the ground, and then calculating the difference between the length of its shadow and its actual height, and applying the same to the shadow of the tree, they ascertained its correct height, thus unknowingly working out a sum in the rule of three. Any person, however ill-informed, might easily get at the exact height of a tree when the sun shines, or during bright moonlight, by marking two lines on the ground 3 feet apart, and then placing in the ground on the line nearest to the sun a stick that shall stand exactly 3 feet out of the soil. When the end of the shadow of the stick exactly touches the farther line then also the shadow of the tree will be exactly in length the same measurement as its height. Of course in such a case the sun will be at an exact angle of 15°. Measurements of this character could be best effected in the summer, when the sun is powerful, has reached to a good height in the heavens, and when the trees are clothed with living green so as to cast a dense shadow. To many to whom this idea might not have occurred, it might be made annually a matter of interest, thus on warm summer days to take the height of prominent trees, and so to compare notes of growth from year to year.—A. D.

## THE HOLLY-LEAVED CHERRY.

WHILE botanising some years ago upon the Pacific coast, we saw what at a little distance appeared to be a fine clump of Holly. A closer inspection showed that it was a Cherry, with leaves so exactly like those of the Holly that the name given it by Nuttall, *Cerasus* (now *Prunus*) *ilicifolius*, the Holly-leaved Cherry, is well bestowed. The plants we met with were directly upon the shore of San Diego Bay, and were not more than six feet high. Farther inland, upon the hill-sides, within the mountain range, it becomes a small tree of twelve or twenty feet in height. The bark is gray and roughish, and the wood close-grained, tough, and somewhat reddish in colour. The engraving from the *American Agriculturist* shows a twig with

Holly-leaved Cherry.

the leaves and flowers of the natural size. The leaves are thick, smooth, and evergreen, like those of the Holly, and armed with very sharp teeth. The flowers, like those of our common wild Cherry, are in racemes, and are succeeded by a handsome deep-red fruit, which gives the deep-green evergreen a most brilliant aspect in autumn. There is another evergreen Cherry in the Southern States, *Prunus Caroliniana*, which is absurdly enough called "Wild Orange," and both belong to the same section of the genus as the Cherry Laurel of Europe. The Holly-leaved Cherry seems to be confined to the southern portion of California, but would probably grow in most portions of that State, and would doubtless serve for ornamental hedges and all other uses to which Holly is put. We brought home some seeds from California, which vegetated, and we should like to know if the plant has ever been tried out of doors in the south of England, and with what result.

## OLD TREES AT FULHAM PALACE.

MR. WILLIAMS (p. 94) seems surprised at finding an *Ailantus* in the form of a timber tree. The *Ailantus* is said by Paxton to have been introduced into England in the year 1751. The oldest tree of it with which I am acquainted is that in the grounds of the Bishop of London, at Fulham Palace. This *Ailantus* measures upwards of 50 feet in height and 6 feet in circumference around the stem. It was probably planted by Bishop Compton, whose name is associated with a Cork tree planted in the year 1666, also with a Judas tree (*Cercis siliquastrum*), evergreen Oaks, and a noble tree of the black Hickory, all of which are still standing. Associated with them may also be seen a magnificent specimen of the *Gleditschia horrida*, the spines of which are some 9 inches long. Bishop Tait's memorial tree is a *Wellingtonia*, which was planted in the year 1858. The grounds at Fulham Palace are richly stocked with fine old trees. The late Sir William Hooker, who often used to pay them a visit, informed me that they once contained the oldest *Liquidambar* in Britain, but, like other relics of the past, this no longer exists there. When gardener there, I often used for bouquets the flowers of a fine old *Pomegranate*, which used to flower profusely on the last year's wood. It grew against the south-west front of the palace. This plant was thought to have been nearly 200 years old. It was killed down to the ground in 1838, on what has been termed Murphy's frost; but it started afresh, and covered a large space of the palace facing the river Thames. Mr. Hayes, gardener to Bishop Bloomfield, used to grow some fine tall scarlet *Geraniums*, say 10 and 12 feet high, and place them on the lawn during summer in triangular fashion, a plan which I continued, and in autumn they used to be the admiration of all who saw them, in consequence of their immense size of truss and profuseness of blossom. I used to plunge the pots in the soil and turf them over close to the stems. I dare say the present gardener, Mr. Henderson, still preserves the style of thus treating these scarlets, which, intermixed among deciduous and evergreen trees, have a fine effect.

D. CUNNINGHAM.

Moor Park.

**Medicinal Properties of the Bay-tree.**—Recommending the leaves of the Bay-tree (*Laurus nobilis*) as an unfailing remedy in cases of fever and ague, M. A. Borain makes the following communication to the Académie:—"I have the honour to acquaint the Académie with the properties of the Bay-tree as a febrifuge and anti-periodic. Mode of preparation: I dry the green leaves over a gentle fire, in a coffee-pot (closely covered, in order to avoid the loss of volatile matters) until they have become brittle, but without allowing them to undergo any further change. I then pound and reduce them to a very fine powder. Mode of administration: I macerate 15 grains of this powder for 10 or 12 hours in a glass of cold water. Two hours before the anticipated time of the attack, I administer to the patient both the liquor and the powder. No abnormal result follows; most frequently the attack does not recur after the use of the first packet. I repeat this medicine three times a day, and for eight days I adopt no other treatment, nor any special regimen. Results: I have not had a single failure in cases of daily or tertian fever, even in those which were not affected by sulphate of quinine. I am convinced that if my remedy were applied in the same way in cases of quartan fevers, it would be equally efficacious.

## NOTES AND QUESTIONS ON TREES AND SHRUBS.

**Poisoning by Privet-berries.**—Not long since, one of our medical journals recorded a case in which two children, who had eaten some Privet-berries, were seized with coma, vomiting, and convulsions to such a degree that had not remedial measures been promptly employed they would undoubtedly have lost their lives.—M.

**Thuja gigantea and Libocedrus decurrens.**—How is it that Mr. Murray, when alluding to these Conifers (page 116), did not point out that the seed of *Libocedrus decurrens* is, compared with that of *Thuja gigantea*, quite large, say six or eight, or perhaps ten times as bulky as that of *gigantea*?—W. T.

**Illustrated Works on Coniferae.**—Can you recommend me a good illustrated cheap book on Coniferae? "The 'Pinetum,'" by Gordon, though good, is not illustrated, so it would not serve my purpose.—WILLIAM JONES, *Edinb.* [There is no moderately-priced work on the subject with plates. Lambert's great work and Lawson's "Pinetum Britannicum" being costly. The latter, too, is only in progress, and the former does not contain the newer species.—A. M.]

**Briar-root Pipes.**—A short paragraph in a recent number of THE GARDEN states that the wood of which these pipes is made is the root of a species of *Smilax* found growing throughout the southern States of America. From enquiries I made some time ago when Briar-root pipes were first introduced, and from an examination of the wood, and comparison of it with that of the tree Heath (*Erica arborea*), I believe them to be identical, I am, moreover, strengthened in this supposition from the similarity of the French word for Heath, *Bruyère*, with the common name Briar, which is probably a corruption of the former. I am told by a large importer and maker of these pipes that the wood comes only from the south of France.—JOHN R. JACKSON, A.L.S., *Royal Garden, Kew.*

## PUBLIC GARDENS.

### NEW PLEASURE GROUNDS IN NORTH WALES.

ONLY a few months since the mountain pleasure ground of Bangor was described in *THE GARDEN*, and already another inclosure of far vaster dimensions is spoken of as being in prospect in a neighbouring part of the Principality. The grandest headland of North Wales, the mountain cliff known as the Great Ormes-head is, it seems, to become a vast pleasure ground, and a carriage drive is to be constructed to the summit, at a cost of £11,500. The scheme appears a promising one, and it is only to be regretted that it is not the munificent gift of some great local landowner; instead of which it is the speculative undertaking of a Company Limited, which will necessarily have to levy the usual black mail in the shape of toll upon the seekers of pleasure on the Great Ormes-head, who formerly, without let or hindrance, sought health and vigour as well as pleasure by the simple and best of all tonics, the mountain breezes of the noble height which looks down upon that pleasantest of Welsh watering places, Llandudno.

That the dues may be light, we may easily conceive—even very light, as otherwise the number of visitors might be too small to realise a sufficient return, in the shape of interest, to the Company, as compensation for its outlay. That any toll or admission money, however small in amount, should have to be charged, is to be regretted; but as the visitors to Llandudno generally arrive with tolerably fat purses, it may be said that the cost of slight tells will be literally of no importance to them. Still, when a choice morsel of our island realm, a spot which from occasional associations of the pleasantest kind has become dear to thousands of people, it is certainly regrettable that steps should be taken which may possibly render it necessary at some not very distant period to repurchase that big breezy playground of our autumnal holiday makers at a vast cost, as has been the case with Hampstead Heath. The principle of English manorial "rights," is a "fearful and mysterious thing," which sometimes works itself out in curiously uninteresting ways. Let us imagine, for instance, that the Great Ormes-head, with all its wild Thyme, all its pretty Club Mosses, all its verdure, in short, and all its picturesque outcrops of naked rock, are in a certain way the property, after a specially English fashion, of some great manorial lord. One may see at a glance that the said manorial lord would never attempt any fencing in, and would make no sort of outlay upon a mountain mass which contains no mineral wealth, and the surface of which is as nearly as possible valueless for pasturage; and so long as he did not, that noble mountain height would have remained open to the free footsteps of whoever might wish to enjoy the keen, pure air, and witness the glorious sunsets across the ocean, which form such a gorgeous spectacle from that commanding height.

But let us suppose that after making a grand road to the summit, and establishing pleasure gardens, conservatories, and pavilions, the speculation should not be found to "pay"—that the undertaking should, in short, prove itself a commercial failure—what then? Why the "Company Limited," wise in its generation, would not throw good money after bad, but might simply abandon the undertaking, and the Great Ormes-head, with its grand road to the summit, would revert to the mysterious lord of the manor, who never fails to appear when anything is to be got, but has the habit of remaining an invisible myth when any outlay has to be made. The next thing would be the prompt action of the steward, bailiff, or agent of the holder of those potential rights—who would advertise the frontages of the said grand road to be let on building leases, and by degrees a street of marine villas might creep up to the top, and the territorial potentates' rent-roll would be increased by £10,000 to £20,000 a year, and our sea-coast visiting population would have lost their dear old Great Ormes-head for ever. But for the present let us look at the brighter side of the question; let us suppose that the "Company Limited" have made such terms with the mysterious owner or owners of the mountain air as would prevent such results as those hinted at, and that failing their own success as a company, they have taken measures to secure to the public an advantageous position in the matter. Such being one of the possibilities of the case, it surely would become necessary that some kind of public supervision should govern the manner and taste of the laying out of the gardens and pleasure grounds on the summit of this favourite public resort.

Primrose Hill and Hampstead Heath have been quite recently saved from desecration by the timely interference of Government; but the grounds round about and within the walls of Rochester Castle have been as recently disfigured and reduced to the aspect of a suburban tea garden, in a manner to be deeply and lastingly deplored. It would, therefore, be to the advantage of the Ormes-head Company to submit their plans in great detail to the criticism

of the public and the press; for the judicious treatment of such a magnificent site is of the highest importance, not only to the public, but also to the company. Upon the broad and skillful treatment of the pathways, plantations, and buildings, in such a manner that, while adding richness and variety to the bare green summit of the great bluff, the boldness and simplicity of natural effects shall not be lost, depends the entire success of the laying out, and its attractiveness as a pleasure ground. The so-called utilization of the Great Ormes-head, in the way projected, will require to be conducted in that truest of artistic methods in landscape gardening, by which the presence of art is concealed; and on such a scale, and in such a position, the task will be one requiring the highest obtainable skill. There are men, two, three, four, half-a-dozen, perhaps, in the whole country capable of carrying through such a task successfully; and there are, on the other hand, hundreds always ready to rush in and make havoc, where genius fears to tread.

There is a glorious little region of bold mountain scenery in the Bavarian Tyrol, that of Bechtisgaten and the Konigs-see, which, under royal auspices, has been manipulated, so to speak, by such artistic skill, as to make precipices, rocks, and ravines, available to the summer rambles of all, without the necessity of their being expert climbers; and this "mending of nature" has been so carefully and so tastefully done that one cannot but admire with what cunning craft an air of natural and unshorn wildness has been preserved while rendering the finest and most rugged spots as accessible as the chief features of a private garden. This is the kind of art that should be employed at the Great Ormes-head, where the plantations must not, of all things, be spotty and mean. Large masses of mountain Pines and other suitable trees should be planted in such fashion as we see them in the great Swiss valley of the Tête Noire, where, and in other parts of the Alps, grand lessons in the art of imitating the aspects of mountain forests might be learnt. In the more sheltered parts, and in suitable aspects, Rhododendron ferrugineum and other mountain shrubs might be introduced, and in others, small herbaceous plants of the hardiest Alpine kinds might be so established as to appear to be a natural growth, while our native Brooms and Furzes, with their rich golden blossoms, should not be forgotten. All this should, however, be done with the utmost skill, and by one of the very best of our horticultural artists, especially by one who has already had experience in simulating wild scenery upon a large scale. It will be very easy to spoil the Ormes-head instead of improving it; and great care should be taken that such a desecration does not take place.

H. N. H.

## THE PROPAGATOR.

### THE ART OF GRAFTING.

(Continued from p. 471, Vol. II.)

#### PROPER SEASON FOR SHIELD-BUDDING.

SHIELD-BUDDING is possible whenever the sap of the stock is flowing, but two distinct periods are most suitable for this operation: 1. In spring, when the sap begins to flow, and when the immediate growth of the graft is desired. This is grafting with a pushing bud. 2. In the course of the summer, and when the graft is not required to sprout until the following spring. This is grafting with a dormant bud. The second method is by far the best, and, moreover, most commonly adopted.

SHIELD-BUDDING WITH A PUSHING BUD.—This mode should be practised at the commencement of the year's growth, so that the graft may be able to develop itself sufficiently, and to ripen its wood before winter. By this method the cultivator hastens the multiplication of rare kinds of plants. By it he obtains at once suitable specimens for market, and these will also supply him in the course of the summer with scion-branches for the late grafting with dormant buds. The method, however, should not be abused by too late grafting, as the forced growth which results from it may seriously affect the stock which has been thus grafted. The scion's branches are cut from the parent tree some time before the flow of the sap; they are then buried at the north side of a wall their entire length in a trench 3 or 4 inches under the surface. When the state of the sap in the stock is such as to allow the bark to be easily detached, the scions are taken up, and their buds shield-grafted by the ordinary methods. As the leaves will have fallen off, the absence of a footstalk will render the handling of the buds less easy in detaching them. The Rose tree, which is readily grafted in this way, furnishes very early in the season young scion-branches, which should be prepared, stripped of their leaves, and used at once as well

have before indicated. Let us again repeat that shield-budding with a pushing bud should not be deferred to a late period; too many gardeners and amateurs err in this respect with their Roses. The Peach tree succeeds better with this method than with winter branch-grafting; but it does still better when shield-budded with a dormant bud. As we shall see presently, the stock, when grafted with a pushing bud, is to be gradually headed down, commencing to do so a week after grafting, in order to promote the growth of the scion.

**SHIELD-BUDDING WITH A DORMANT BUD.**—A bud is termed dormant which does not sprout before the spring which follows the time of its insertion. The months of June, July, August, and September are the proper times for inoculating a dormant bud. The exact moment for operating depends on the state of the sap in the stock. The older stocks, whose growth ceases early, should be grafted first; after them the young and vigorous ones. Bearing this distinction in mind, tall standards should be grafted before low ones; a stock of the current year's growth later than one of former years; the Plum tree and the Wild Cherry earlier than the Sainte-Lucie and the Almond tree; the Pear on its own roots and the Hawthorn sooner than the Quince and the Apple. Maples and Ash trees later than Chestnuts and Lilacs. If it is apprehended that the

The young scion tied up to the stump or heel of the stock.

sap of the stock will cease to flow before the scions are sufficiently ripened, the tops of the latter should be pinched a fortnight beforehand, in order to accelerate their ripening, and the nearer the time of grafting the shorter are they to be pinched. However, if pinched too short and too soon, the latent eyes of the scions will shoot and branch before the time of ripening, and the scions will consequently be useless. On the other hand, the vegetative powers of the stock may be prolonged by the aid of waterings and stirring the soil around the roots. Thus retarded in the one subject and accelerated in the other, the sap at last comes into something like a condition of harmony or equality in both stock and scion. Stirring up the soil around the roots a few days before grafting tends to promote the activity of the sap; repeating the operation the day after will serve to maintain the growth and favour the union of the graft. It would not be prudent to bud when the sap is too abundant, as it would smother the bud. Failure need not be feared if the operator waits till the sap has lost somewhat of its activity, when the bark no longer detaches itself freely from the wood, and the mornings become cool. In shield-budding, from the middle of August to the middle of September, kinds which vegetate to a late period of the season, care must be taken to assist the union of the graft by tying

the branches of the stock together at the time of grafting. As soon as the grafting is completed, the ends of these branches are cut off for one-third of their length; the flow of the sap will thereby be arrested, and the union of the graft will be the result. Subjects of a luxuriant habit of growth should be treated in this manner. Two or three weeks after budding, the subjects should be gone over, and, where the buds have missed, the stocks should be rebudded. The failures are easily recognised by their black or wrinkled bark. But, as the sap has by this time almost ceased to flow, the lost currents of it, so to speak, must be sought at the neck of the lateral branch, or on the stem under the base of a vigorous branch. Certain kinds of Roses succeed best with this late budding.

#### TREATMENT AFTER BUDDING.

Those stocks which are rich in sap when budded late should have the ends of the branches lopped or clipped if they are in a shady position, or if the mass of their leafy branches prevents a free circulation of air around the graft. If this were done with vigorous stocks, budded earlier, there would be danger of causing them to shoot prematurely, and in their case it will be sufficient to tie their branches together, or to bend the budded branches and fasten them to the stem of the stock. Grafts that are too tightly bandaged must be relieved by cutting or untying the bandage. If the union of the graft is not complete the bandages should be renewed or the old one retained after being loosened. It is better to wait until the winter is over before removing the bandages from grafts that are likely to suffer from the cold. Those stocks that have suffered from tightening of the bandages should have some of their largest top branches shortened with the sécateur or the pruning-knife. The heading-down of stocks budded with a pushing bud should be commenced a week after budding, and the branches should be cut away successively, and also the stem to about 4 inches above the graft as soon as the union of the parts is ascertained. In the case of subjects budded with a dormant bud, the stock is to be amputated as soon as the frosts are over, and before vegetation has commenced, by a single cutting about 4 inches above the graft. This stump of 4 inches serves for tying up the young graft, and is to be cut away at the end of the summer following (at the place indicated by the line B), first operating on those subjects which are slow to heal, and those stocks which differ most in kind from their grafts. In this work the saw, the ordinary pruning-knife, and the stump cutter are used. Stakes or props should be continued for a few years.—*C. Ballet.*

(To be continued.)

**Fertilization of Cyclamens.**—I would feel greatly obliged by a little information as regards the fertilization of Cyclamens, as I have some good varieties.—*W. BEALBY.* [Choose a fine sunny day in the last fortnight of this month or the first one of March for the operation. Let the male plant be of vigorous constitution, with large finely-variegated leaves, and having a good shaped corolla, the segments of which should be long, broad, blunt at the ends, each having a slight but regular twist. In selecting the female be more particular than with the male, and in all cases use only flowers of pure and unspotted colour. Take hold of the stalk of the male flower between the forefinger and thumb of the left hand, immediately underneath the flower, and with the right-hand thumb, tip the flower, and the pollen will fall out, and lodge on the thumb-nail of the left hand. Having previously selected the female plants, apply the pollen to the stigmas of four or six of the finest flowers, and be careful in the operation, for rough and injudicious handling often results in failure. Remove all the other flowers from the plants whose flowers have been fertilized, and place the plants in a rather shaded portion of the greenhouse or pit.]

**Influence of the Stock.**—*M. Decaisne* regards as wholly unproved all the assertions that fruit is ameliorated or in any degree altered by being grafted upon a Quince or any other stock. We think he is wrong.

**Varieties of Roses Produced by Budding.**—*M. Zen* has contributed to the Royal Institution of Venice a paper in which he declares that, after long study and experiment, he has succeeded in producing new varieties of Roses by budding. The budding was effected in the usual way; but it appears that when the flowers were produced they were very different in form, colour, and markings from the parent stock; that these variations became intensified with age, according to the vigour of the plant; that the variation is persistent, and may be reproduced by layering, grafting, or budding; that if the variation be lost it may be reproduced by repeating the original experiment under like conditions; that the results of experiments differ in the case of different Roses. *M. Zen* intends to communicate his plan to the Institute.

## CLIMATE AND VEGETATION.

BY ALEXANDER BUCHAN, M.A.

*(Continued from p. 118.)*

## I. NORTH AMERICA, WEST OF THE ROCKY MOUNTAINS.

THE regions from Vancouver's Island northward, and Lower California, have climates widely differing from each other. The former of these regions is characterised by an abundance of moisture at all seasons, and the latter by a deficiency of moisture also at all seasons. In New Archangel, Queen Charlotte Islands, and the continent adjoining, the prevailing winds are westerly, with a considerable proportion of southerly and easterly winds in winter, and north-westerly winds in summer; hence the rainy character of all the months. Since, however, the easterly winds, which also frequently blow in winter, come from the continent, are very cold, they serve the important end of effectually checking growth, and thus affording to vegetation that rest which seems to be essential to the existence of many species. Over the whole of this region luxuriant forests abound. On the other hand, in Lower California westerly winds are much less frequent in winter, and those which do occur, do not blow with the force and persistency which they acquire further to the north, and dry easterly winds from the continent are much more frequent. At San Diego the annual rainfall is only 8.8 inches, and in none of the cold months does it reach an average of 2 inches. In summer, winds are westerly and north-westerly, and observations show that they do not come over a large portion of the Pacific; and since at this season temperatures very rapidly increase inland, Lower California is almost a rainless region, only a tenth of an inch of rain falling at San Diego during the three summer months. Over the whole of this region there are no forests, but only a few scattered stunted trees and shrubs. The region between these two partakes partly of the character of each. From November to the middle of April there is a generous, if not an abundant, supply of rain, owing to the prevalence of strong westerly winds from the Pacific; whereas little if any rain falls, particularly during the five months from May to September. This is the general character of the climate over this region in places which are open to the Pacific, situated either near the coast, or on the higher slopes inland which are not shut in to westward by ground still higher than themselves. But vast tracts are enclosed between the different chains of mountains running north and south through this part of America, over which the winds, already drained of their moisture, pass arid and dry, and consequently rain scarcely falls there. From the relation of this part of America to the prevailing winds, and from the contour of its surface, an endless diversity of climate is the result, and especially the middle portion of the vast region extending from Alaska to Lower California presents more sudden transitions of climate, and climates more sharply contrasted with each other, than any other portion of the globe can parallel. Hence this region offers the best field for the study of the geographical distribution of species, in so far as they are, or may have been, determined by climatic conditions.

## II. NORTH AMERICA, EAST OF THE ROCKY MOUNTAINS.

The forest zone of the United States, comprising the slopes of the Alleghanies and their continuations northward, the northern slope of the Ohio basin, and the lower plains of the Mississippi on the west, enjoys one of the best climates on the globe. As a consequence of its relation to the Gulf of Mexico, the prevailing winds, and the general path storms take in crossing it, it follows that the winter rainfall increases generally in advancing from the Rocky Mountains eastward over the States; over the whole of the Alleghanies it amounts to from 2 to 4 inches a month, excepting the low ground at the mouth of the Mississippi, where the fall is greater. In summer, since the prevailing winds are a portion of a vast aerial current which has swept through the West Indies into the Gulf of Mexico, and thence changed from an E. and S.W. into a S. and S.W. course, the supply of rain is ample; and further, since the temperature rises to northward and north-westward, and falls only very slowly to north-eastward, the rainfall is not excessive, being generally from 3 to 5 inches each month. One marked feature in the rainfall at all seasons over this region is the remarkable uniformity of its distribution, arising chiefly from the circumstances that the range on the Alleghanies lies in a N.E. direction. Since, then, this range does not lie across the path of the moisture-bringing winds, but along their course, either side is equally well watered. It would be difficult to name any other country affording climatic conditions better adapted for the growth of trees, and for the great staple products of agriculture. The eastern part of the prairie region, comprising fully a half of the whole of it, appears to be as favourably situated, so far as the rainfall is concerned, as the greater part of the forest region of the Alleghanies. The rainfall during the winter months is a little less, but fully equal in amount to that of the east side of Great Britain in the same season. In the summer

months the rainfall of the eastern portion of the prairies equals that east of the Mississippi; but in the months of April, May, and June, it is greater. Hence the opinion that the treeless character of the prairies is due to a deficiency of the rainfall is incorrect. All observations show this; it is only in the upper reaches of the prairies where a decided deficiency of rain is felt. In the lower prairie grounds the average results show no deficiency; droughts doubtless occur, but not more so than in Australia, and many other countries.

## III. BASIN OF THE MEDITERRANEAN.

The peculiarity of this region lies in its summer rainfall, which depends on the direction of the prevailing winds and on the high temperature of the land as compared with the sea at this season. These winds are originally part of the great westerly current of the Atlantic, which, on approaching the Peninsula and the south of France, assume a northerly direction and blow southwards on Africa. The result is that the south of Spain, the north of Africa, and the shores of the Levant have no rain in summer; and little rain falls in Spain, the southern half of Italy, Turkey, and Greece, and nearly the whole of Asia Minor. The mountains which environ this basin and break it up into parts have important bearings on the climate through the rainfall at all seasons; and hence the great variety of its climates, not violently contrasted, but yet well marked, which cannot but exercise a great influence on the distribution of species.

## IV. REGION OF THE CASPIAN SEA AND CAUCASUS MOUNTAINS.

Here there are extraordinary contrasts of climates at all seasons. The region sloping down to the eastern part of the Black Sea is well watered by rain in each month of the year, and the same remark applies to the country sloping down to the south-western portion of the Caspian, particularly in the winter, spring, and autumn months.

In the north of the Black Sea the prevailing winds in winter are easterly, but in the eastern portion of the Black Sea they are N.W.; hence the difference in the rainfall of the two regions. In the same season the winds on the Caspian are E. and N.E., and, consequently, the vapour which rises from the Caspian is borne forward to the south-west angle, and being arrested by the Elbrus mountains, falls in copious rains. At Lencoran 51 inches of rainfall in the year, and an average of from 4 to 8 each month, from September to May, and the result is a rich tropical vegetation. Nearly the whole of the rest of the region surrounding the Caspian is an arid waste; at Astrakan  $4\frac{1}{2}$  inches only, and at Novo Petrovsk  $5\frac{1}{2}$  inches, fall in the year. In summer the prevailing winds over Europe and western Asia are W. and N.W. Hence in the extreme east of the Crimea the soil is parched and bare, but across the Straits of Enikali and a little to the south, rains are frequent and the vegetation luxuriant. In the low plains of the Kuban the rainfall is scanty, but on the higher grounds sloping up to the Caucasus, against which the N.W. winds strike, the rainfall is abundant; thus at Alaju, 2,070 ft. high, from May to September the average is about 6 inches each month. With this sudden increase to the rainfall there is a total change of climate and vegetation. This part of the globe comes next to California and neighbouring states for the immense variety of sharply-defined climates which it presents, and perhaps excels it for the number of the climates which may be considered as localised within very contracted limits. Hence it presents an excellent field for the study of the distribution of species in relation to climate.

## V. NORTHERN INDIA.

Over this region little rain, if any at all, falls during the cold months of the year. But on the southern slopes of the higher ranges a good deal of rain falls, and snow at still greater heights. Thus at Nynce Tal, 6,433 feet high, the average rainfall of December, January, and February, is  $4\frac{1}{2}$  inches a month. Thus, in this respect, height brings about an important change of climate; and since all less elevated districts to the north of such ranges of hills are rainless, the varieties of climate, and the transitions of climate, often sudden and abrupt, are very great.

In summer the distribution of the rainfall is very remarkable. In the west of India, south of Kutch, the S.W. monsoon prevails, and since these winds come laden with the moisture they have licked up from the Indian Ocean, in a passage extending over from  $30^{\circ}$  to  $40^{\circ}$  of latitude, or between 3,000 and 4,000 miles, the rainfall along the whole of the west slope from sea level upward is excessive. But, north of Kutch, the prevailing wind changes to W.S.W., W., W.N.W., and finally N.W.; and since a W.S.W. wind traverses a comparatively narrow breadth of sea, and W. and N.W. winds become land winds, the rainfall from Kutch northwards diminishes with extraordinary rapidity; and, along the Indus, and particularly to west of it, no rain falls, the country is parched up, and the temperature rises as high as it probably does anywhere on the globe. While this occurs on the plains, it is otherwise on the southern slopes of the mountain

ranges, such as those of Cabul, which overlook them. On these slopes frequent showers brought by the southerly winds fall, and there, accordingly, the climate and vegetation assume a totally different character. On the other hand, at Calcutta the prevailing wind in summer is S. or rather S.S.E., and a steady aerial current blows up the valley of the Ganges. Since such a current coming, originally over fully 3,000 miles of ocean, incessantly pours vast volumes of vapour into the Gangetic basin, the rainfall of this valley in summer is very great, and continues very large even to the head of the valley. But cross this valley westward into that of the Indus, the rainfall quickly, if not at once, sinks to little or nothing, and we encounter nothing but a waste tract of sand. Here, then, is a region which offers, in the splendid contrast of its climates (from the almost rainless district of Spiti to the maximum of humidity in Khasya), a tempting field to the student of nature in tracing out the influence of the variations of climate on organic forms and on their distribution; and it has an advantage the Caucasian and Californian regions do not possess, in the facility with which a staff of naturalists could be organised for an exploration of it, more or less exhaustive.

In the Introductory Essay to the "Flora Indica" of Hooker and Thomson (p. 36) there occurs the following sentence:—"The geographical distribution of plants, which is in very many respects the most interesting branch of botany, has made very little real progress of late years, owing to the confused state of systematic botany; for we do not consider rudely cataloguing the ill-defined species of limited areas, or loosely defining geographical regions, by the supposed prevalence of certain natural orders or forms of vegetation, as calculated to advance directly the philosophy of distribution, however useful such regions are to the beginner, or such catalogues to the systematist." No doubt very much has been done of late years with reference to this most attractive subject, not merely in the accumulation of facts of the highest value, but more particularly by such inquirers as E. Forbes and Wallace, in seeking to connect the present species of organised beings and their distribution with those of past time. Notwithstanding this, the sentence quoted from the "Flora Indica," is, in a large sense, still substantially true. The state of systematic botany, and the loosely defined geographical regions of plants, seriously obstruct the prosecution of the inquiry in such a way as might conduce to the discovery of the laws of distribution. Thus, if we wish to investigate the climatic conditions either necessary for the full development of a species, or sufficient to set the bounding limit to its distribution where are we to find the facts of its distribution defined with an approach to the preciseness which the problem demands? And be it here noted, the progress of meteorological research is showing us more and more clearly, that even such comparatively small countries as Scotland afford very much greater contrasts of climate than were supposed, as respects those vital elements of climate, moisture and sun-heat. Watson's "Cybele Britannica" is a wonderful store-house of facts regarding the distribution of the British "Flora;" but even in this work the limits of distribution are not precisely enough defined. For it must be kept in view, that the climatic influences determining this distribution which it is sought to trace will often prove to be of a very subtle character, and the horizontal and vertical limits of distribution will require to be very accurately stated. If this were done, the causes which arrest the spread of a species might be inquired into at different points along its limiting line, from which some satisfactory conclusion might be arrived at as to whether there were conditions of temperature or moisture, of soil and of geological formation, or of the inroads of any of the plants' natural enemies, whose attacks it could not withstand in the struggle for existence. Since, then, we cannot hope to obtain this information in any single work which covers so extensive a field as "Cybele Britannica," we must turn to the quarter to which Sir Walter Elliot drew attention in the opening address last year, viz., Local Natural History Societies, whose chief and proper province ought to be, as it certainly is, to collect and disseminate such information. Towards this end, I would suggest that these societies should be invited, from time to time, to prepare monographs of the distribution of a few naturally allied species within their own limited districts; and that these monographs be illustrated with physical charts of the district, on which the boundary lines of each species would be set down,—not by a general blur or dash of colour indicating its existence over a district, but by marking off the localities where it has been formed by clearly defined lines, in the same way in which isothermal, isobaric, and magnetic lines are drawn, or in which the facts of geology are depicted. If these societies possessed a plate of the physical features of their district, the expense of these illustrations would not be great. Such, however, is the paramount importance of the information thus collected and discussed by local societies, as concerns the lasting and solid progress of botany, zoology, geology, and the allied branches of physical research, that the

expense of publishing such monographs and illustrations, and of liberally disseminating them among scientific men, ought to be defrayed by such bodies as the Royal Societies of London, Edinburgh, and Dublin, who should be entrusted with funds supplied to them for this purpose by the Government, as suggested by Mr. M. Home in his opening address to the Royal Society of Edinburgh in December 1870.

Again, if desirous of inquiring into the effects of climate in effecting changes in a greater or less degree on vegetable forms, we set about to collect the facts of the distribution of these forms,—such as the varieties of species, the species of any particular genus, or other allied groups,—a great difficulty soon faces us, arising out of the confused state of botanical catalogues. And this state of things is conspicuously apparent in the case of those very plants we naturally select, viz; those whose instability of form (if the expression be allowed) and intimate natural alliances mark out as peculiarly suited for the investigation. It need scarcely be remarked that this is a field wherein much heavy work is required of botanists,—heavy work, demanding at the same time extensive knowledge and well disciplined systematising powers. This branch of botany can be reformed and placed on a satisfactory basis only by a series of monographs of genera, in which each genus and its species are exhaustively dealt with. We might then hope to arrive at some definite and truly scientific knowledge of the laws determining the distribution of plants;—how, for example, a change of a few degrees of temperature affects the distribution; a greater or less rainfall; different distributions of temperature and rain, at certain critical epochs; and how the occurrence of a certain degree of cold in winter, on the one hand, effectually brings about the destruction of some species, and on the other secures the preservation of other species by affording them the annual rest they require.—*Transactions Roy. Botanical Society, Edinburgh.*

**The Wettest Spot in Europe.**—Mr. Isaac Fletcher, M.P. for Cokermonth, who has for several years kept rain gauges at various stations among the Cumberland mountains, has published in the *Carlisle Journal* the records of each month during the year 1872. His gauge at Seathwaite, at the head of Borrowdale, has been established for nearly 30 years, and the returns of the past year show that in the lake district, the rainfall of 1872 has not been exceeded in any year during that period. The following figures show the total rainfall at each station during the whole year, the numbers in parentheses indicating the height in feet above the mean level of the sea:—Seawell Pike (3,200), 90·75 in.; Great End (2,982), 91·40 in.; Brant Rigg (695), 118·68 in.; Esk House (2,550), 121·27 in.; Wastdale Head (247), 131·30 in.; Sprinkling Tarn (1,986), 170·33 in.; Styhead Tarn (1,472), 177·04 in.; Seathwaite (422), 186·25 in.; Taylor's Gill (1,070), 224·73 in.; the Sty (1,077), 224·73 in. The number of wet days at Seathwaite during the year (the only place where this record of wet days seems to have been made) was 228. Mr. Fletcher remarks:—"The amount registered on the Sty—nearly 244 in.—is marvellous, and is greatly in excess of any previous record. In 1866, 224·56 in. were recorded. So far as has yet been ascertained the Sty is the wettest spot in Europe, and, except in tropical countries, the quantities I have quoted represent the two greatest annual falls of rain that have ever been recorded."

**Root and other Parasites.**—The following parasitical plants are now fully established at Glasnevin:—1. *Orobanche Hedera*, growing on Ivy, propagated by bringing roots of Ivy which were infested with the parasite, and grafting them on roots of Ivy which were growing in the garden. 2. *Orobanche minor*, growing on the roots of *Trifolium medium*, propagated by sowing the seeds of the parasite along with the seeds of the Clover. 3. *Lathræa squamaria*, growing on the roots of several kinds of trees, propagated by digging up tufts of the plant, and planting it among the roots of trees growing in the garden. Of *Cuscuta* we have had six different species growing in one season, but they are not permanent, and require for the most part to be kept up by sowing their seeds annually, and assisting them to attach themselves to the supporting plants on which they prefer to grow. We have made several attempts to establish the yellow Bird's-nest, *Monotropa hypopitys*, and also the common Bird's-nest Orchid, *Neottia nidus-avis*, but hitherto without success. The latter lived and flowered a second year after it was brought into the garden, which gives some hope of success by further perseverance.—D. MOORE, *Glasnevin.*

**New Fibre Plant.**—A fibrous plant, called *Apocynum venetum*, has been discovered growing wild in such quantities in Turkistan that it may be expected soon to make its appearance in the market. Its fibres, as tender and delicate as Flax, as strong and tenacious as Hemp, are, by combining the qualities of the two, greatly superior to either. The Russians will probably endeavour to transplant it to Europe, an attempt which might be made by other countries as well.—*Times.*

## THE HOUSEHOLD.

## LILAC-STEMMED MUSHROOM.

AGARICUS (TRICHOLOMA) PERSONATUS.

This is one of the commonest and best of all British agarics, and there is little fear of mistaking it, when its salient characters are once known. It grows everywhere abundantly in pastures and grassy places, generally late in the autumn, and appears sometimes in immense quantities after heavy rains; at these times its flesh becomes saturated with moisture, and unfit for the table. It is said to have been sold at one time in our markets under the name of "Blewits," but of late years it has never appeared. In colour it is throughout very pale brown, almost white, or pallid buff, with the exception of the upper part of stem, which is usually tinted with a pale but lively purple shade, hence its popular name of "Blewits," or Blueits. The pileus is smooth, or greasy and bibulous, the stem solid, ringless, and slightly scaly at the purple apex; the gills have a tendency to separate from the stem, as shown at c; hence Fries, the great Swedish botanist, some time since removed the plant to the *Lepista* section of *Paxillus*, under the name of *Paxillus personatus*, whilst Cooke, in his new handbook, following a suggestion of Mr. Worthington Smith,

*Agaricus* (*Tricholoma*) *personatus* (Lilac-stemmed Mushroom); meadows and grassy places, generally late in autumn; colour, pale brown, almost white, top of stem pale purple; diameter, 7 inches or more; height, 4 or 5 inches. A. Section; B. Spores enlarged 700 diameters.

elevates *Lepista* to a genus (on account of its white spores, as contrasted with the red spores of *Paxillus*) and describes our plant under the name of *Lepista personata*.

*A. personatus* is closely allied to *A. gambosus*, and the recipes for cooking the latter exactly apply to the former, but care should be taken to gather the specimens in dry weather, and when not soddened with moisture.

The best mode of cooking *Agaricus personatus* is either to mince or tricassee it with any sort of meat, or in a *col-au-vent*, the flavour of which it greatly improves; or simply prepared with salt, pepper, and a small piece of bacon, lard, or butter, to prevent burning, it constitutes of itself an excellent dish.

Served with white sauce, it is a capital appendage to roast veal. It may be broiled, stewed, or baked.

**BREAKFAST AGARIC.**—Place some fresh-made toast, nicely divided, on a dish, and put the agarics upon it; pepper, salt, and put a small piece of butter on each; then pour on each one a tea-spoonful of milk or cream, and add a single clove to the whole; bake twenty minutes, and serve up without removing the glass until it comes to the table, so as to preserve the heat and the aroma, which, on lifting the cover, will be diffused through the room. It dries very readily when divided into pieces, and retains most of its excellence. A few pieces added to soups, gravies, or made-dishes, give a delicious flavour.

## GARDEN STRUCTURES.

## THE FUTURE OF Hothouse HEATING.

The present famine price of fuel is not an unmixed evil, for if it teaches nothing else it will compel thousands of the unthinking to realise the fact that wanton waste makes woeful want. At this season the luxury of a good fire is a forbidden comfort to tens of thousands, and yet whether examined socially or commercially, the great fact cannot be ignored that one-half, if not two-thirds, of the fuel consumed in Great Britain and in her commerce is wasted. What is the smoke nuisance that converts our manufacturing towns into dungeons but fuel unconsumed? And yet the consumption of smoke is in a nutshell if we only go the right way about it. But smoke, like coal, will not burn without fire, and when a fire is properly lighted the consumption of smoke is a simple matter. What we want to make our firemen understand is the fact that smoke is waste—so much money daily sent up the chimney; at present nine-tenths of those who have the management of fires merely regard smoke as a natural consequence of combustion. While this state of ignorance prevails not only in the garden, but upon the "rail," the mill, the manufactory, the domestic household, in fact, everywhere where fuel is consumed, we must not be surprised if fuel remains at a famine price. In our domestic arrangements open fire-places, as at present constructed, are a costly but necessary nuisance. It is, however, pleasing to find that the Society of Arts has taken the matter in hand, with the offer of handsome prizes, for improved fire-places, and if inventors only handle the subject aright good results must follow.

The great error, so far, in all attempts to extract a maximum effect from a minimum cause has been that of forcing highly heated and perhaps arid air into the atmosphere to be heated, without previously diluting it with fresh air, and if necessary moistening it. When, nearly thirty years ago, the "Polmaise" fever was at its height, this fact was apparent, but then hot-water pipe was cheap. Strikes and extortion had not increased it fifty per cent. in a few months, so that then a large surface moderately heated could be indulged in. Now, concentration is the order of the day, so much so that if the present price of iron continues, water will cease to be the carrier of heat to our plant-houses, and steam or warmed air philosophically applied will take its place. The saving in the first "plant" will be enormous, while the extraction and utilisation of fire from fuel will be reduced to a certainty. All that is necessary for the purpose is an affiliation of sound practice to sound philosophy; the gardener must either call the man of science to his aid or philosophy must court the confidence of practice. That this forecast is not a dream I feel fully convinced. The circumstances of the times demand the change and culminate it must. I throw out the hint, and would advise those who are bothering their brains about intricate boilers, to hark back a little, take a second thought, and see if heat cannot be extracted from fuel and be conveyed where it may be required in a much more simple and natural manner than by means of water as a carrier.

Given a heat generator and a reservoir filled with hot air, cooled, aerated, and moistened to the proper state for admission among tender vegetation, how shall we carry it where it is wanted, and distribute it according to the exigencies of cultivation? That is the problem which requires solving, and those who are acquainted with the working of steam "blowers" and "fans," as used in smelting and foundry enpolas, should not be slow in devising the means of distribution, and in small "plant" of substituting self-acting power for steam power. The latter would only be wanted where a number of houses required to be heated from the same source, and then if it is air in motion that is wanted, why anything, from the soft sighing of a May morning to an African sirocco may be commanded. Neither need we grumble about the cost—a steam-engine may be bought nearly for the cost of a first-class boiler, while every atom of heat generated could be utilised in the reservoirs. Although all this may appear to be a wild, chimerical dream, this is not the first time that the subject has haunted me. For thirty years and more, it has from time to time been cropping up, but never with sufficient weight to force its adoption. Now, the price of material speaks loudly enough, and the price of fuel says reduce the waste, or the pleasure of glass houses must become, as it was half a century ago, a luxury in which the wealthy only can indulge.

But it is not from a gardening point of view only that this subject demands investigation, for once establish a reservoir of heated air, with the power of filtering—medicating if necessary, and delivering it where and when you like, and the difficulty of heating and airing blocks of buildings at once vanishes; for there is no more reason why the fresh air which is forced into the Houses of Parliament or other public buildings should not be drawn from healthy hills miles away in the country, than that fresh water should come

from the valleys in the same locality. From a health-invigorating point of view, pure air and pure water are twin elements, and, therefore, if in dense centres of population one element is worth carrying, why not the other? Town life would thus be shorn of one-half of its terrors, and frequenters of crowded assemblies, instead of being compelled to inhale over and over again impure air, might fancy themselves miles in the country. Such things may not come to pass in our time; but they will come—the times demand them, and come they must. The domestic aspect of this subject is greater even than the commercial, for though it may take some time to wean a Briton from the ancient extravagance of an open fire, the time must come, if our coal sighters are correct, when dire necessity will compel him to consider his sensual rather than his visual faculties. Without, however, running to the extreme of close stoves, there is ample scope in our open grates to extract three times the quantity of heat that we at present get from them without any increase of fuel, but before that is accomplished we must have a complete metamorphosis in the construction of our fire-places, and the waste up the chimney must be controlled. WILLIAM P. AYRES.

**Patent Terra Cotta Stoves.**—Now that winter has fairly set in, it may not be out of place to direct attention to these ingenious contrivances for heating purposes. The boiler of our early vinery failed the other day, and we had recourse to one of these stoves to supply its place until another boiler could be got. It was fitted up in a temporary manner, and the heat which it gave off astonished everybody, although the amount of fuel consumed was small. With one filling, the fire was kept going for the space of 46 hours, the only attention it had during the whole of that time being to check the draught, when the proper heat had been obtained. Charcoal would doubtless be a better fuel for it than coal, but the makers affirm, that by using their smokeless patent fuel the expense may be reduced to 2d per day. The apparatus being portable, too, is a point in its favour.—C. ARNEY, *Hatfield House*.

**Heating by Paraffin Lamps.**—The paragraph in page 102 was well timed. I have a good-sized conservatory at the back of the house in which I live, which contains several half-hardy succulents and other things, and such plants as *Diclytra spectabilis*, &c. Hitherto I have entirely kept the frost at bay by using a paraffin lamp, placing it in the house at eight o'clock in the evening when frost was imminent, and leaving it to burn till eight o'clock in the morning. I simply place it in a box of soil on the floor of the house; and, notwithstanding the prevalence of cold easterly winds during the time the frost lasted, which played right on the house, owing to its exposed position, I found in the morning quite a genial warmth diffused through the house, without any disagreeable smell resulting. The lamp should be turned as full as possible, but not to a degree sufficient to cause it to smoke. It is only when a paraffin lamp is turned down low that a disagreeable smell is given forth. I think a knowledge of the simple fact I have here stated deserves to be widely distributed; for there are many amateurs especially who have glass structures without any means of heating them, and who are put to some trouble in frosty weather to preserve their plants from harm.—RICHARD DEAN, *Ealing, W.*

**The New Conservatory in the Central Park, New York.**—This building is to be erected in the Fifth Avenue side of the Park, opposite Seventy-fourth Street. It is to be a conservatory for music and flowers. The upper storey will be used for botanical plants and flowers, and the lower storey will have a grand music-stand in the centre. There will also be seats for the people. The building is to be 230 feet long by 50 feet wide. This conservatory, the foundations of which are being laid, will have a grand Fifth Avenue entrance on Seventy-fourth Street, and it will extend from Seventy-third to Seventy-fifth Street. The contracts for the building are to be made this winter, and the whole thing is to be completed next fall. The two circular ends are to be used for flowers. They are to be surmounted by glass domes. One is to be for Ferns, and the other for Camellias.

**Dennis's small Greenhouses.**—Through the kindness of our townsman, Dr. Hopkinson, I have had an opportunity of inspecting one of these useful little structures, and I must say their cheapness, good workmanship, and utility, render them very satisfactory contrivances. The house in question was only finished in March last, and this autumn the gardener had a very respectable crop of Grapes in pots in it.—R. GILBERT, *Burghley, Stamford*.

**Weeks's Upright Tubular Boiler.**—While staying near Croydon, during part of my Christmas holidays, I was shown over a recently made nursery there, and was struck with the novel way in which one of Weeks's Upright Tubular Boilers had been set. In consequence of having a rather deep stoke-hole, it was found very inconvenient to feed the fire at the top; to obviate this difficulty, the boiler was taken out and reset, not perpendicularly as before, but horizontally, the largest end of the boiler being turned towards the feeding doors, and the lower portion acting as fire-bars. This alteration is doubly economical, as by its adoption, fire-bars are not only dispensed with, but the water heats quicker than when the boiler is set in the ordinary way.—R. SPERBER, *Eastington Park, Stratford-on-Avon*.

## WORK FOR THE WEEK.

## PRIVATE GARDENS.

**Flower Garden.**—Notwithstanding the inclemency of the weather, Snowdrops, Hellebores, and Winter Aconites still continue to expand their blossoms; Crocuses too are blooming freely, as has also been the lovely *Scilla bifolia*, which, however, has been in some cases injured by frost; nevertheless, bulbous plants in general are making good leaves that still seem unscathed. Wallflowers are now blooming freely, and different kinds of *Viola*, *Arabis*, and *Aubrietia* are beginning to unfold their flowers, although the weather is at present anything but favourable for spring blooming plants. Daisies and *Hepaticas* also promise a profusion of floral beauty, while walls are ornamented with the cheerful yellow blossoms of *Jasminum nudiflorum*, and *Chimonanthus fragrans* in many places is still in good condition. *Berberis Aquifolium*, and *B. Darwini*, with its small leaves and deep golden flowers, likewise contribute nobly to the enrichment of our gardens now, and will continue to do so even more extensively during these next two months. All empty flower-beds should receive a good dressing of leaf-mould and decayed manure, and be deeply dug or trenched. Where hardy material can be spared for replenishing flower-beds and borders, planting may be proceeded with. Pansies, Daisies, *Arabis*, *Alyssums*, and similar early blooming plants transplant as well now as later in the season; indeed, if carefully removed, they suffer little or no check in the operation. Ground for the reception of hardy herbaceous plants should be trenched and heavily manured, but the subsoil, unless good, must not be incorporated with the surface soil. Where *Lythrum roseum* is used in ribbon-border making, it should now be lifted, cut up into good crowns, and replanted in a line about 15 or 18 inches apart. *Salvia fulgens* in light soils may be treated in the same way. Sweet Peas should now be sown where they are to bloom, and some should be put in beds from which to make up deficiencies in case of failure; sow a few in a box under glass. Sow also some *Mignonette* in rows or broadcast where early blooming plants of it are wanted to flower. Some *Saponaria calabrica* seeds should be sown on a wall border for transplanting. A few seeds of *Tropæolum canariense* may also now be sown in a similar position, and a few twigs of broom stuck in front, so as to protect the young plants, when they come up, from cold winds and frost.

**Bedding Plants.**—Where two, three, or more *Pelargoniums* were placed together in one pot in the lifting season for convenience of storage, they may now be separated, potted singly, according to size, and kept without water for some days after the operation. Keep the house or frame rather close for some little time after potting. Lose no time in obtaining and striking as many cuttings of all plants as possible, for the stronger they are and the earlier propagated, the hardier and more vigorous will they be when turned out in the latter end of May. *Calceolaria* cuttings seldom root well in spring; nevertheless, the tops of autumn-saved plants may be economised for that purpose in the event of an otherwise deficient supply. *Verbenas*, *Heliotropes*, *Ageratum*, *Tropæolums*, *Petunias*, *Lobelias*, *Coleuses*, *Alternantheras*, *Iresines*, &c., when rooted, should be potted singly or transplanted into boxes, and still be kept in heat, as their tops can very soon be taken off for the same purpose, and also their side shoots, so that, with plenty of heat and convenience, a large supply may be obtained before the end of the next two months. Sub-tropical plants must also be increased as expeditiously as possible. Side shoots taken off for cuttings soon make good plants. Seeds of the various kinds commonly raised by that means should now be sown in a brisk hot-bed or warm pit. *Acacia lophantha*, *Wigandias*, *Cannas*, *Ferdinandias*, *Ricinus*, *Zeas*, and many others, can be readily raised from seeds. *Canna* roots saved from last year should now be divided and started in heat. *Dahlia* roots may also be started. If beds be dug out about 18 inches or 2 feet deep, and filled with leaves trodden firmly, so as to be covered by a frame, and some light rich soil be placed therein, they will form excellent positions in which to plant *Calceolarias*, *Verbenas*, or *Heliotropes*, so as to have grand plants before they have to be set out in beds. Similar frames are useful for pricking Stocks, *Asters*, *Marigolds*, *Tagetes*, and other things, into.

**Conservatories.**—In addition to *Hyacinths* and other bulbous plants, these also contain blooming plants of *Camellias*, *Azaleas*, *Chinese Primroses*, *Cinerarias*, *Salvias*, some zonal *Pelargoniums*, *Daphnes* of different kinds, *Cytisus*, *Zieria Smithii*, several *Acacias*, *Heaths*, *Epacris*, *Boronia serrulata*, *Libonia floribunda*, *Tremandra verticillata*, *Correa cardinalis* and *Brilliant*, *Monochadum serceum multiflorum* and *ensiferum*, *Lachenalias*, *Roella ciliata*, *Oldenburgia Deppiana*, *Pyrethrum uliginosum*, *Leucopogon lanceolatus*, and *Luelia gratissima*. Amongst climbing plants, *Hibbertias*, *Kennedys*, *Hardenbergias*, *Brachysemas*, &c., are now coming beautifully into flower. Amongst dwarf climbers nothing is prettier at present than

nice plants of *Myrsiphyllum asparagoides*, loaded as they are with a profusion of little reflexed white flowers, having orange-coloured conspicuous anthers. This is a plant that may be readily raised from seeds sown in a hotbed, pricked or potted off singly when up, and kept growing in moderate heat or in a cool house, either will do, only when a little warmth is employed good plants are sooner obtained than by cool treatment. Pot such roots as remain of *Primula cortusoides* in a compost of good loam two parts and leaf-mould one part, with a little sand. Those previously potted and beginning to grow, keep on a shelf as near the glass as possible. Give a final shift to herbaceous *Calcceolarias*, and also to some of the shrubby ones intended for conservatory decoration. *Cinerarias* required for late blooming should have plenty of root room and water, and be kept in a cool, airy house. The least confinement of the roots is sure to cause the plants to flower prematurely. A few *Balsams* and *Cockscombs* for early flowering should be sown in a hotbed, and pricked off before they become spindly. Of *Amarantus salicifolius* a few seeds should likewise be sown for conservatory ornamentation, as well as for flower garden decoration. To succulents starting into growth water should occasionally be given, so as to keep the soil moderately and uniformly moist. The general potting of greenhouse plants should now be proceeded with. Begin with those that have commenced to grow, and which are most forward, having the ball moderately dry, and the soil used in potting in a similar condition. Do not give water after potting to such plants as have been at rest or kept comparatively dry during the winter, until they show that they need it. From *Cinerarias*, *Calcceolarias*, &c., water must not, however, be withheld. In potting make the new soil as firm as the old, otherwise it only forms a channel for the water to run through without penetrating the old soil, thus greatly impairing the health of the plants.

**Orchids.**—A general overhauling and repotting of the several species should now take place. Before potting, however, withhold water for a few days, in order that the roots may be more easily freed from the old soil. *Miltonias*, *Dendrobiums*, *Bletias*, *Brassias*, *Cyrtopodiums*, &c., should be potted as they begin to grow; while *Cattleyas*, *Angraecums*, *Saccolabiums*, *Vandas*, and *Aerides* should be potted before they start into growth. *Calanthes*, when they fairly show signs of growth, should be repotted. For epiphytal Orchids, the pots or pans used should have a small pot inverted over the hole in the bottom, and then they should be filled up with broken crocks and charcoal to within 3 inches of the top; terrestrial Orchids require less drainage. The former require only a spongy material, or compost consisting of fibrous peat and sphagnum, which should not be pressed too hard. The latter require soil of a more nutritious character, such as turfy loam, leaf-mould, or peat, and rotten horse or cow-dung. Water must be carefully or rather sparingly given at first. Some will require fresh blocks, and any found to do better on blocks than in pots should be supplied with them. Orchids in general seem fond of non-resinous woods; therefore, cork, Apple, Pear, Plum, and Maple blocks are more in demand than those of deal or Pine wood. Some kinds grow best in baskets, a supply of which must also be got in readiness for them. Place some roughly broken crocks in the bottom, with rough peat and sphagnum on the surface, to firm the plants.

**Indoor Fruit and Forcing Department.**—The end of this and the whole of next month is the recognised period for the general spring potting of Pines. Have, therefore, a good stock of material at hand, including turfy loam, charcoal, and half-inch bones. Pot suckers at once, if necessary, but if they be weak allow them to remain for a time on the plants, even after the fruit is removed. Increase the temperature a little and apply water more plentifully. For Cherries a high temperature is ruinous, especially before the fruit has set well. A night temperature of 45 is sufficient, and water should be given only moderately. Thin Grapes as soon as they are large enough to admit of the performance of that operation; thin and stop shoots also, and regulate growth generally. Tie up to the wires such Vines as are intended soon to be started, but leave undisturbed such as are to be permitted to come naturally into growth. Sprinkle plenty of water on the paths and on other bare surfaces, in order to maintain a moist atmosphere. Thin the fruit of early Peaches, but not too much, as the final thinning should not be performed until the stoning period is over. Prune trees in late houses, the buds of which are almost ready to burst, and ventilate freely so as to retard their too early progress. If the midday sun be hot, and the weather frosty, rather allow a more than usual rise of temperature than admit frosty air too freely. Maintain a steady bottom heat of 80 for early pot Figs. Strawberry plants, the fruit of which is colouring, should be kept near the glass, in a moderately dry house, at a temperature of 60° or 65°. Water carefully, for too much would impair the flavour of the fruit. Bring in or shift from a cool house to one that is warmer, plants for

succession. Cucumbers and Melons sown last month will now be sufficiently strong for planting out. Keep up for them a steady bottom heat, either by means of hot water or fermenting material, and water them with tepid water. Sow a few more seeds for a later crop.

MARKET GARDENS.

The snow which we have had has left the ground cold and wet. Its condition should not, however, delay trenching, digging, and manuring operations, which should in all cases be pushed forward. In light or moderately dry soils, early Potatoes must be got into the ground at once. January planted Lettuces have suffered rather severely; but to make good deficiencies from the frames at present would be useless work; better wait until the end of the month, when under any circumstances they must be turned out. Seakale should be earthed up from the alleys between the rows. It is commonly grown in rows a foot or so apart. For forcing, one or two rows are lifted, leaving every alternate two for spring produce. Over those left several inches of soil should be turned from the space out of which the forcing roots were taken, finishing the whole somewhat like broad, flattened Celery ridges. Now is the time for sowing the main crop of Onions; but to do so in many cases is impracticable, owing to the saturated state of the soil. As soon, however, as fine weather or a fine day or two comes, the crop should be sown. Continue to protect Radishes, and to prepare ground for a fourth crop. Preserve Cauliflower plants from frosty winds, covering up all frames in which they are growing at night and during wet or snowy weather. Sow some seeds of Knotted Marjoram in a gently-heated frame for transplanting in May, in alleys or rows, in a plantation by themselves, or between rows of Leeks or Lettuces. A few Cucumber seeds for early frame use should now be sown, also some Tomatoes and Chilies. The same frame will do for all. On a very slight hotbed, and near the glass, some Celery seed for early crops may be sown, also some Lettuces and Cauliflowers, should the supply of the latter be deficient, in frames or under hand-glasses. In any case, some sown now comes in usefully between the autumn and general spring sowings. Lettuces from among young Carrots should be the first to be transplanted, so as to give the latter room. Continue to force Rhubarb, Seakale, and Asparagus as required, and see that some Rhubarb crowns in the open air are covered.

COVENT GARDEN MARKET.

FEBRUARY 11TH.

**Flowers.**—These are well supplied in the shape of cut flowers, plants in pots, and spring-flowering plants. Amongst cut blooms we noticed those of Roses, Camellias, Azaleas, *Cinerarias*, particularly deep blue and red-coloured kinds; Chinese *Primroses*, *Cyclamens*, *Lily of the Valley*, *Astilbe* (*Spiraea japonica*, *Deutzia gracilis*, *Snowdrops*, *Hyalinths*, *Acacias*, especially the beautiful *A. Riciana* and several *Orchids*, the latter consisting chiefly of *Dendrobium mobile*, *Celogyne cristata*, *Trichopilia suavis*, *Odontoglossums*, *Epidendrums*, &c. Vases are filled with flowers of various colours by turning the plants out of their pots and reducing their roots so as to allow several plants to be accommodated in a small space. Spring flowers brought to market with some damp Moss around their roots, whether in bloom or not, command a brisk sale.

**Fruit.**—The supply and demand as regards fruit are about equal. Newtown Pippin Apples continue good, and of that kind there is a fair supply; they arrive in excellent condition, without any packing whatever, not even a lining of paper being put next the wood of the barrels in which they are imported. The Apples are packed so closely as to prevent any movement. English Pears consist of Easter Beurré and Ne Plus Meuris, large quantities of the former being imported from the Continent. Pines are less plentiful than they were a fortnight ago. West Indian and Spanish fruits are good, and Oranges are improving in quality.

**Vegetables.**—From Cornwall and the Channel Islands large supplies are daily obtained. Young Peas, French Beans, Potatoes, &c., are moderately well supplied. Saladings and ordinary vegetables are plentiful and good.

# THE GARDEN.

"This is an art  
Which does mend nature: change it rather: but  
THE ART ITSELF IS NATURE."—Shakespeare.

## THE INDOOR GARDEN.

### COCOS WEDDELIANA.

(LEOPOLDINA PULCHRA).

To this truly elegant Palm allusion has already been made in THE GARDEN for 1872 (p. 313), but the magnificent plant of which we now give an illustration deserves to be more fully described than it was on that occasion, being, as it most undoubtedly is, one of the finest specimens of the kind in Europe. Culturally speaking, it is one of the *chefs d'œuvre* of the celebrated collection of plants at Mauley Hall, a collection that has done much to elevate the general tone of plant culture in the North of England. This graceful South American Palm has thirty-seven fine leaves on it, some nearly five feet long, and all of them beautifully recurved. These drooping fronds are of a deep and glossy green, collectively forming a noble plume of finely divided foliage.

Like many of the other Palms in the Mauley Hall collection, this plant fruits very freely, bearing an abundance of fertile seeds, from which Mr. Petch, the gardener there, has succeeded in raising young plants. The male and female flowers of this species are small, and are borne together on the same spadix. After fertilisation has taken place, the female flowers are succeeded by oblong or egg-shaped fruits about the size of a common Hazel-nut. The fruits of this species are not so obviously three-sided as are those of other species of the same group, the common Coconut (*Cocos nucifera*) for example. When fully developed this Palm is an effective addition to either the plant stove or warm conservatory, while as an exhibition plant it stands unrivalled. It grows freely in fibrous loam and a little coarse sand, and when in active growth it requires a moist atmosphere and an abundant supply of water at the root.

### RUSSELIA JUNCEA AS A BASKET PLANT.

This formed some years ago one of our most elegant exhibition plants, but it has now fallen almost out of cultivation. It is a free-growing, light, and airy stove plant, with long drooping branchlets, tipped in the blooming season with myriads of bright scarlet, slender, tubular flowers, each about an inch long, and not more than a tenth of an inch in diameter; hence, whether in bloom or not, it forms a very elegant plant. Its drooping habit renders it peculiarly suitable for basket cultivation, and, though one plant after two or three seasons' growth would form a very graceful mass, it is better for the purpose of immediate effect to plant four or five

in a group. Assuming that you have a basket 18 inches in diameter, and of proportionate depth, line the inside first with live Sphagnum, to which may be added some of the smaller Lycopods. Then fill it with a compost, consisting of rough fibrous loam three parts, flaky half-decayed leaf-mould, and dry cowdung made sufficiently hot over a flue or stove to destroy insect life, one part, and a liberal admixture of charcoal, broken oyster shells, and some gritty sand. Mix the whole intimately together, having it at the same time rather dry, and then fill the baskets quite firmly. In the centre, however, place a soft porous 6-inch pot, with the hole at the bottom stopped up, and this kept constantly filled with weak manure water will be found of great service, especially in the second and after years of the growth of the plants. Taken out and examined, it will be found that the roots will have wrapped

*Cocos Weddelliana*, (syn. *Leopoldina pulchra*).

round it in a perfect network. The basket being ready, procure some *Adiantums* and other small-growing Ferns and Lycopods; fill them in as a fringe around the sides, and as they grow they will form a desirable covering for the basket work. Then plant your *Russelias*, placing them equidistant around the circumference of the basket, and cover the surface with a few more dwarf-growing plants. The temperature of the house should be that of a damp stove, from 60° to 75° by fire-heat, rising to 90°, with plenty of moisture in the atmosphere, in bright weather. As the plants get established and the roots become active, the syringe must be freely used, with tepid water, on all sides of the basket; and if sometimes clean weak manure water be added to it, growth will be thereby promoted. In the matter of watering plants in baskets, it is necessary that it be done thoroughly, so as to soak the whole mass of soil; and if this cannot be done by simply pouring water upon the surface, then the basket must be lowered into a tub containing sufficient warm weak manure to soak the whole thoroughly. For permanent plants this steeping of the soil will be necessary at the commencement of growth in spring, and perhaps once a month through the summer and autumn. This, however, will depend much upon the copious manner in which

the plants are syringed: the surface of the basket being large and the air hot and sometimes dry, the evaporation will be much greater than it would be from a pot or tub containing a similar amount of soil. The branches of the *Russelias*, as they gain strength, will rise to the height of 5 or 6 feet, and the branchlets, drooping, in the most graceful manner, will form a living fountain of exquisite beauty. To bloom the *Russelias* successfully it is necessary that the maturing process be properly attended to in the autumn—that is, the quantity of water must be reduced towards the middle of August, the plants be exposed to full light and a free circulation of air, and in that manner the blooming principle is sure to be encouraged. Through the winter keep the plants dry rather than otherwise, but at the same time see that they do not flag. When growth commences in spring, each tiny branchlet will be tipped with flower buds in various stages of develop-

F. W. BURBIDGE.

ment, so that a succession of flowers will be maintained for a long time. Of course in the blooming season manure water must be supplied, and by copious syringings, sometimes with sulphur water, the plants must be kept clear of red spider, which is a sad pest to them. A.

### CEROPEGIAS.

THESE constitute a small genus belonging to Asclepiads. They have all more or less tuberous or thick filiform roots, slender, creeping, or ascending stems, and opposite leaves; their flowers, which are remarkable for singularity of form, and, in some species, striking beauty, are borne mostly in small umbels, which continue in perfection for a considerable time. Ceropegias, coming as they do chiefly from Africa or India, are mostly stove plants; those which are natives of the southern parts of Africa enjoy a somewhat drier and cooler atmosphere than the Indian kinds, and have larger tuberous roots; they should be potted in well-drained good rough sandy loam. In propagating them, the cuttings should be inserted in sand and placed in a brisk heat, but they should not be kept in too close an atmosphere, or they are liable to damp off. The following are a few of the handsomest species:—

**CEROPEGIA GARDNERI.**—This is a free-growing handsome stove climber, which is very ornamental either trained upon a rafter, pillar, or upon a wire trellis: in the latter case a balloon-shaped one is best. The leaves, which are opposite and some 3 inches long by 1 inch broad, are dark green above but paler and tinged with dull purple below. The flowers are produced in small umbels from the axils of the leaves; the corolla tubes are contracted in the middle, leaving both the lower and upper portions bulged out; the limb is five-lobed, the segments curving over the throat and becoming temporarily united at the points, giving them a peculiar corona-like appearance. The ground colour is white, over which is distributed a profusion of large and small spots and blotches of purplish-brown. As has just been remarked, the pots for this species must be well drained, and a little peat will be found a beneficial addition to the compost in which it is potted. During summer it should have plenty of water, but in winter it must be given very sparingly; still it will not bear what is called drying off. When it begins to grow repeat, but at no time will it require much pot room. It blooms from May to the end of July. It is a native of Ceylon.

**C. ELEGANS.**—This is another attractive plant, and one that has been long in cultivation, having been introduced from the East Indies about the year 1824. Its roots are filiform and fleshy; its leaves smooth and dark green, and its flowers are produced in abundance during July and August; they are large, and in shape are similar to those of the preceding species; they are purple in colour, ornamented with numerous small green spots, the margins being deep purple, and furnished with long, shining, black hairs. The treatment recommended for *C. Gardneri* suits this species admirably.

**C. BOWKERII.**—This singular and truly elegant species comes to us from South Africa. It is not a climber, and does not require the temperature of a stove, although a little warmer place than an ordinary greenhouse suits it best. Its roots are large and tuberous. The stems, which are slender, erect, and some 12 or 18 inches in height, bear opposite linear-subacute leaves, about 2 inches long, and of a pale green colour. The flowers are upwards of an inch and a half long, the prevailing colour being sulphur yellow, and, unlike the previously-named Indian kinds, the long segments are not erect and contiguous, but reflexed so as to cover the tube; the throat of the corolla is purplish brown, whilst the oblong segments are sulphur coloured, spotted with emerald green, and beautifully fringed at the edges with long, soft hairs. The stems are herbaceous, and during winter it should be kept dry, its thick tuberous roots enabling it to withstand such treatment with impunity; but during the growing season it enjoys an abundant supply of water and plenty of sunshine and strong light.

**C. SORORIA.**—This resembles the preceding, and is a native of the same country. It has thick tuberous roots, and, like *C. Bowkerii*, requires a dry season, or period of rest. It

differs, however, from that kind in having a climbing, or rather a twining, stem. The leaves are opposite, linear-lanceolate in shape, about 6 inches long by half an inch or rather less in breadth, and deep green on the upper side, but paler beneath. The flowers are larger than those of *C. Bowkerii*, and, as in that species, their lobes are reflexed, and not erect and contiguous; but the segments do not completely cover the tubes, in consequence of its large size; the ground colour is pale green, shading off into yellowish green towards the upper portion of the tube, which is moreover dotted with reddish pink; the reflexed lobes of the corolla are an intense deep green, transversely banded with blackish purple upon the upper side, the lower surface being soft pink, through which the transverse bands on the upper side are plainly visible; the edges are sparingly furnished with short hairs. It blooms during May and June. In point of beauty and interest, few plants surpass these last two species, both of which are natives of Kaffraria.

**C. OCLATA.**—This is an old but extremely beautiful species, the flowers of which somewhat resemble the head of a snake. In habit it is scandent and slender; the stems are ovate, or ovate-cordate, and are furnished on the upper surface and at the edges with a few hairs. The flowers, which are large and handsome, are largest at the base; the tube is long, yellowish green, and spotted towards the upper part, the apex of the blooms being vivid green. This species requires a stove, and produces its flowers in August and September. It is a native of Bombay.

**C. THWAITESI.**—Although at first sight this seems nearly allied to *C. Cumingiana*, yet it is sufficiently distinct from that kind to render it worth growing along with that plant. It is a slender climber, which produces green and brown flowers in abundance; the base of the flowers is much inflated, and the tube strikingly contracted near the middle. It blooms during September and October. It is a native of Ceylon.

**C. STAPELLEFORMIS.**—This is a somewhat stout plant, the stems being nearly 2 inches in circumference, round, smooth, and dull green. The flowers are large and showy, and are produced mostly in pairs on long slender branches. These latter are dark purple, and issue from between peculiar spiniform masses on the main stem. The corolla is large, inflated at the base, and contracted a little above the middle, white tinged with green and profusely spotted with dark purple; the tube is hairy within and the sides reflex, giving fully developed flowers a grotesque appearance. This species, which is a native of the Cape of Good Hope, blooms during April and May.

**C. CUMINGIANA.**—This superb Javanese species is a slender climbing stove plant. Its leaves are cordate at the base, and membranous in texture, dark-green tinged with brown. The flowers are large and showy, and are produced in clusters of from six to ten; the ground colour of the tube is creamy white; the limb being rich purple and chocolate with pale coloured streaks. It blooms in profusion during July, August, and September. G.

**The Tree Pæony Indoors.**—Few are aware what striking and excellent plants tree Pæonies are for forcing and decorative purposes. Amongst them there is no end of varieties of bold, characteristic beauty. No flower is more conspicuous at a long distance, its glowing shades of colour shining forth with brilliant effect. Indeed, the distinct and striking characters of the whole plant are points of excellence rarely seen combined in one species. Little trouble or care is required to have tree Pæonies in perfection in February and March. Plenty of light is the most essential thing in their culture at that period; they should be placed as near the glass as possible, plunged in a mild bottom-heat, and occasionally syringed. The temperature of the house need not exceed 50° or 55°.—*Florist.*

**Tuberoses.**—I bought some Tuberose roots last January, and grew them in pots, but none have produced flowers. Is there still any probability of their flowering? Nearly all the leaves have died off.—**J. CLARK.** [The bulbs of the Tuberose (*Pollanthes tuberosa*) are of little use after a season's growth in England; consequently they are in general only grown one year, and a fresh supply obtained for the succeeding one from importations annually made of these bulbs from Italy. As your bulbs have not flowered during the past summer, they may possibly do so in the coming one. Keep the roots pretty dry just now, and in the end of the month pot them into 6-inch pots, using light rich turfy loam, and place the pots in a gentle heat until they begin to grow. Transfer them then, after gradually moving them to a lower temperature, to a position near the glass in the greenhouse. Unless they flower this summer they will not be worth further trouble.]

## THE FLOWER GARDEN.

### HUMEA ELEGANS FOR OUT-DOOR DECORATION.

For planting round or near fountains placed in the centre of a flower-garden, this plant stands unrivalled. Its graceful drooping tresses of silky brownish orange-coloured flowers, which glitter in the sun, when moved by the breeze, give it a charm beyond description. Although introduced from New South Wales about the beginning of the present century, it is only of late years that this biennial has been used to any extent for out-door decoration, and it may be truly said that no plant gives more grace to the *tant ensemble* of the garden than it does. Whether as a back line to a long border, as a single specimen to let into the lawn, or for the centre of a bed or vase, it is most charming; and as its culture is easy, and its period of beauty extends from May till November, a brief notice of how it may be best grown may not be unacceptable to your readers.

In June, sow the seeds in a pan of light soil, and place it in a warm frame until the plants are in rough leaf; then remove

*Humea elegans.*

them into a cool frame, where they can receive plenty of air, and slight shading during hot sunshine for a fortnight, when they will be ready to pot off singly in thumb pots, using light rich soil for the purpose, and plunging the pots to the rim in sand or saw-dust. Keep them close and shaded until sufficiently strong to stand out, when they must be gradually exposed to sun and air, after which they will only require to be covered with a glass sash during cold or wet weather. Shift them into larger pots throughout the autumn and following spring, as they require it, taking care not to let them become pot-bound, as their beauty is much lessened by being in any way stunted, either in pot room, moisture, or richness of soil. By liberal treatment they will retain all their foliage in a healthy green state until finally destroyed by frost. During winter, a low temperature, plenty of air, and being kept near the glass, suits those intended for planting out better than heat and a close atmosphere. Give plenty of water before turning them out of the pots, and also for a week or two after planting, until they are fairly established in the soil, which should be composed of turfy loam and well decayed manure or leaf-soil.

When kept under glass to flower in pots for indoor decoration, they are not half so beautiful as when exposed to the open air, their colour indoors being a kind of greenish pink, which gives the plants a sickly appearance. Slightly fumigating them during the spring months will keep them free from insects, which are apt to infest the under surface of their foliage. For our illustration of this plant we are indebted to Messrs. E. G. Henderson.

J. S.

### BOUVARDIAS.

THESE handsome plants cannot be too extensively cultivated, for the sake of their brilliantly-coloured and fragrant flowers. They are easily grown in a light, sandy soil, or in a mixture of peat and loam. The dwarf kinds may be grown in pots, and planted out in groups, and the more vigorous kinds in raised flower-beds in the open air during the summer, late-flowering species being repotted in autumn, and transferred to plant-houses and rooms. They are easily propagated, either from seed or from soft-wooded cuttings struck in light soil, in pots or under a frame, in a very strong, moist heat, giving them but little or no air. In a short time they will be fit to repot, after which they should be again placed for some time under a frame with the air excluded. A good deal of air may be afterwards given, but the heat should be always kept up. They are also propagated from portions of roots taken from good plants and kept in heat during the winter. The roots are to be cut in pieces about half an inch long, planted vertically in pots, and placed under a frame in heat, with the air excluded. In from eight to fifteen days, most of them will have sent out shoots, and they should then be treated in the same manner as cuttings. The plants from which the roots have been taken will afford good cuttings if they are repotted and placed in a strong heat with the air excluded. Such plants, however, soon die. Roots taken from bad plants, which have been exposed to the cold the whole winter, will send out shoots, but soon perish. Success in propagating these plants depends on not operating before the end of February or early in March, on using vigorous herbaceous cuttings, placing them in a very strong and moist heat, and repotting them as speedily as possible. Plants raised in this way will be fit to remove into the open air in the following May or June. All the species are not capable of being propagated from root-cuttings; for instance, *B. angustifolia* and *B. jasminoides* hardly ever send out shoots when treated in this way, while *B. Davisonii* and others succeed admirably. The last-named kind (*B. Davisonii*), which is also known as *B. Vreelandii*, cannot be too highly spoken of. It is a vigorous grower, with a compact habit, and produces a profusion of white flowers throughout the whole year. *B. Queen of Roses*, which has the same habit, is a fine kind with very fragrant rose-coloured flowers, and *B. alba odorata* is invaluable for its still more fragrant flowers and compact habit. These last three are most valuable plants.

DONATIEN GUIHENEUF.

### WALLFLOWERS.

PROBABLY many who reside in and around London are hardly aware of the vast breadth of Wallflowers grown in many of the market gardens near that city, from which to supply Covent Garden and other metropolitan markets with the bundles of blossoms one sees in such quantities in early spring. The type or strain grown for market is of a dwarf bushy growth, which produces an abundance of dark, richly-coloured flowers. Growers who cultivate Wallflowers for the London markets select the plants from which they take the seed to supply their annual crops with the greatest care. They must have habit, colour, and precocity, for it is an important matter to be able to get flowers into market as early as possible. In the western suburbs of London, especially, there can now be seen large patches of dark Wallflowers coming rapidly into good bloom. Of all the strains of dark Wallflower yet offered by seedsmen—even in small packets at a large price, and with high-sounding names—nothing can excel the beauty of the market strain. A few years ago quite a distinct type, known as *Young's Blood*, came from the midland district, and it had the appearance of having been selected from the double German strain. The flowers of this are large and of a rich blood-crimson hue, but the petals are long and loose; it is of tall growth, and the majority of the plants lack a free branching habit. The seed of Wallflowers imported from Germany yield many shades of colour—among them purple and violet colours—but, though attractive masses can be formed of these, they are not nearly so popular as the dark strains of English growth. Yellow Wallflowers are being sought after and improved in the present day. There is one strain especially which finds much favour in the spring garden, that known as the Belvoir Castle dwarf yellow. This is of a dwarf branching

habit, and when quite true forms charming masses of a clear pale yellow hue, without any stain or trace of dark among it. By careful selection this can be obtained in a form well adapted for edging purposes. What is known as the yellow Tom Thumb is of a taller growth, and of a deeper hue of colour, but very pure and effective; the flowers are stout and of good form. A really good purple strain would be very acceptable, and the wonder is it has not been forthcoming ere this. The choice old double types of the Wallflower, such as the double yellow, double orange, double purple, double dark, &c., good and valuable though they are, are not grown in our gardens as they deserve to be. In cottage gardens, however, they may be frequently met with in beautiful condition. These are invariably increased by cuttings, which strike readily. The genus *Cheiranthus* also includes some fine species and hybrids, such as *C. alpinus*, *C. oehroleucus*, *C. mutabilis*, and *C. Marshalli*, which are perennial in character, and the plants last for years, increasing in size with age if allowed to remain undisturbed. They are of a very close and compact habit of growth, and bloom most profusely in dense close masses, and the flowers take the form of trusses, and not that of spikes, as in the case of the varieties of *C. Cheiri*. Of those just named, the two former (sometimes these are called *Erysimums*) are very similar in colour, and are generally regarded as being identical, the flowers being of a pale yellow hue. *C. Marshalli* has strong orange flowers, stout in texture and fine in shape, and it makes a grand bed or ribbon border in spring, while single plants in borders are highly effective. These kinds yield plenty of seed pods; but, for some reason, the seeds never become matured, and therefore they must be propagated by cuttings. After the plants have done blooming, they make a quantity of young shoots, and, if these are taken off about July or August, and pricked out in a bed in some light sandy soil on a shady border, or placed under a handglass, they soon take root, and grow into strong plants by the following spring. It would seem that *C. Marshalli* is for some reason much the scarcer of the three, and by some cultivators it is thought not to be so readily propagated.

R. D.

**Sparaxis pulcherrima and Thunbergii.**—The Rev. H. Harpur Crewe, in a communication to one of our contemporaries, speaks in high and well-deserved praise of these two plants. While justly stating that they are "very elegant and striking," he has, however, omitted to notice their very great difference in habit, and in fact rather speaks of them as if they were much alike. *S. pulcherrima* is by far the finer and more elegant of the two, its flower-stems growing to a height of 4 feet or more, and arching over at their extremity in a broad and graceful curve, from which the beautiful pensive flowers hang on long thread-like stalks. *S. Thunbergii*, although a very handsome plant, has nothing of the graceful waving beauty displayed by the tall, slender, arching flower-stems of *S. pulcherrima*. It has a stiffer habit and is a much dwarfer plant, with erect flower-stems seldom more than 2½ feet high. The flowers, moreover, have very short stalks and are not pendulous like those of *S. pulcherrima*.

## NOTES AND QUESTIONS ON THE FLOWER GARDEN.

**Flowers and Shrubs for a Steep Bank.**—I have a bank about 8 feet high, and 50 yards long, steep, and with a little brook running below it through my garden. It has a northerly aspect, but is very sheltered. Can any of your readers suggest how it may be made as ornamental, by flowers or shrubs, as I am sure it could be if rightly handled?—COUNTRY PARSON. [Your best plan is to naturalise hardy plants on your bank.]

**The Battle of Life among Plants.**—The last number of the *Popular Science Review* contains an interesting paper on this subject. Experiments are described where numbers of plants were placed together in the same bed, and certain plants, after a few years, alone remained, the others having succumbed. One of the most persistent was found to be the Couch Grass; and, in general, plants with a large root area showed most vitality in all soils.

**Drying Plants.**—I am intending, if all is well, to make a tour in the Holy Land. May I ask you to be so kind as to let me know where I can procure the best appliances for drying and preserving flowers; and, indeed, would you kindly tell me what they ought to be?—W. E. [Suitable paper for drying and preserving plants can be obtained at Mr. Newman's, 9, Devonshire Street, Bishopsgate Street. A good-sized portfolio with long straps would be most convenient to take with you. See our article on "Drying Wild Flowers" in THE GARDEN for August 31st, 1872, Vol. II., p. 196.]

**The Common Garden Marigold (*Calendula officinalis*).**—This is without exception the most remarkable of all hardy biennials in its persistent winter blooming qualities. Plants raised from seed sown in July have been in blossom the whole of the winter, and seem to defy any weather short of intense frost. How bright and cheerful the flowers look under the leaden skies of midwinter! And the colour is the richest and mellowest orange to be found in any flower that blossoms. This old-fashioned Marigold is well worth attention, as it sometimes develops a form and density of petals that would not discredit the finest Aster. Some day we shall see it elevated to a better position, and gardeners will then wonder that its charms should have been so long overlooked.—A. D.

## THE ARBORETUM.

### THE MOVEMENT OF THE SAP.

IN common with other readers of THE GARDEN, I am greatly pleased with the new theory in reference to sap movement, as expounded by "A. M." (see p. 92). As the discussion of this interesting topic may be attended with good results, I wish to state that whilst I concur with your correspondent in his conclusion "that there is no descent of the sap in autumn," I would explain the fact in a somewhat different way. To follow "A. M." step by step, I beg to suggest that the process of the ascent of the sap is mechanical, and the result of pressure from below, and not of suction from above. The sap being an exudation from the roots, and formed at a uniform rate and in uniform quantity, must by the mere force of its own pressure rise upwards, exactly in the same way as mercury rises in a barometer from the expansion of the mass. When the sap, in this manner, reaches any part of the plant, growth commences, and by the changes which the sap undergoes during its deposition, the wood, leaves, flowers, of every plant are produced. There is, then, no question as to the ascent of the sap in spring and summer. I think the mechanical theory explains the mode of its ascent more rationally than the "suction" theory of "A. M.," which is not suction in the strict sense of the word, but only the assimilative power exercised by the tissues of a plant upon the food brought into contact with them; this food, which we term sap, being pressed or pumped upwards by the ever increasing formation of the sap from the root-action that is going on below; so that, to put the matter in plain words, for every ounce of sap which is exuded by the roots, another ounce of sap, previously formed, is driven upwards, by reason of the *vis a tergo* acting upon it. And if further explanation be necessary, I would add that were there no penetrative tissues for the transmission of the sap upwards, the substance of the plant would be burst in all directions. I agree with those who dispute the old theory of a descending sap. The first question which any intelligent botanist would ask, when the idea of a descent is suggested, would be *enī bono?* Where is the sap that is to descend? It is quite certain that every particle of sap that has ascended throughout the season has been assimilated by the plant, leaving no residue; for as autumn supervenes, and the changing temperature causes the leaves to die and fall, the roots also are similarly affected, and their sap-producing power gradually diminishes until it ceases altogether in the majority of cases. This rational account of the matter explains why Professor McNab could not in any of his experiments discover the sap descending. It is not, as "A. M." puts it, that the pump has lost its suckers, but that there are no suckers at all, and no sap remaining to be sucked, or to ascend. It does not cease to ascend for want of the continued suction which "A. M." assumes, but solely because the root-action, which produces the sap, has ceased, and no more can be supplied until the plant has had an interval of rest—that long winter's sleep during which tired nature's power becomes resuscitated.

ROBERT M. CHAMNEY.

**Mountain White Pine (*Pinus flexilis*).**—This species, to which allusion is made at page 128, occupies the sub-alpine belts of the Rocky Mountains and the Sierras. It differs very much in size. At 10,000 feet altitude it is a tree of 130 feet high, and is from 2 to 3 feet in diameter; but on the high exposed crests of the Sierras and Mount Shasta, it is reduced to a mere straggling shrub, creeping on the ground. The cones in consequence vary considerably in size. Where the tree has obtained a stately size, as is the case on the mountains of an elevation of 10,000 feet a little east of Little Yosemite Valley, its cone measures from 4 to 5 inches; but where it is reduced to a mere shrub, they are scarcely from 1 to 2 inches long. It is a fine tree with tapering trunk and conical outline, branching almost from the base; the lower branches are horizontal, the upper ones ascending. The wood is white and soft; the annual rings from one-eighth to one-half line, on an average one-fourth line wide. In the Rocky Mountains it occurs from New Mexico to the forty-ninth parallel, never forming entire forests. There it associates with *P. contorta* and *P. aristata*. On the high crests of the Sierras it is found growing along with *P. contorta* and *Abies Pattoniana*. The species sometimes described under the name *P. albicanis*, and *P. cembroides*, is *P. flexilis*.

HARDY TREES AND SHRUBS.

BY GEORGE GORDON, A.L.S.

THE CRETAN MAPLE (*ACER CRETICUM*).

THIS forms a handsome sub-evergreen small tree, from 15 to 30 feet high, with a round, dense spreading head. It is a native of Greece and Naples, particularly of the mountains in Crete and the other islands of the Grecian Archipelago. It was first introduced in 1752. The leaves are small and variously shaped, but mostly more or less bluntly three-lobed, rounded at the base, and set on short footstalks. They are dark glossy green above, smooth on both surfaces, three nerved, of a thick, leathery texture, and, according to the rigour of the winter, more or less persistent. The lobes are entire or slightly crenated on the edges, and the lateral ones, when present, the

*Acer creticum*.

shortest. The flowers are greenish yellow, and are produced in the end of May, in few-flowered, terminal, erect, or slightly nodding corymbs. The fruit or keys are small and smooth, with thick carpels and parallel wings, placed rather distantly apart. This Maple is sometimes named in botanical works *Acer obtusilobum*, and must not be confounded with the *Acer creticum* of the nurseries, which is *Acer heterophyllum*, an

Fruit or Keys of *Acer creticum*.

evergreen bush, seldom more than 4 or 5 feet high. The finest example of this rare Maple in England, or perhaps anywhere, is at Syon. This tree is, at the present time, 32 feet high, with an ample head 16 feet through, and a stem 9 feet in girth 2 feet from the ground. The length of a full-sized leaf is 2 inches, including the foot-stalk, which is about an inch long, and the breadth is 1 1/2 inch.

THE YELLOW CYPRESS.

THE Yellow Cypress of Vancouver Island, and the north-west coast generally, is certainly *Cupressus nutkaensis*, and not *Thuja gigantea*—a tree which I have shown in a former note is universally known in British Columbia and the northern tracts of North-west America generally, as “the Cedar.” In Vancouver Island *Thuja gigantea* and *Cupressus nutkaensis* are the only two native Cupressineae, and the latter is very little known to the general body of the colonists, or even to the lumbermen, whose knowledge of it is derived chiefly from its occurrence on the coast further to the north. Wherever I have seen it, either in Vancouver Island, British Columbia, Washington Territory, or Oregon, Newberry’s description applied to it very well indeed. It is essentially a northern and not a southern tree. Towards the south, only a few stragglers are found, and generally, as in Vancouver Island and southern British Columbia, at considerable elevations. There it is always a ragged tree, in most cases little more than a large shrub, and agreeing, as I have said, excellently with Newberry’s description. As you travel further to the northwards it attains its maximum of development—commencing to be a common tree just as *Thuja gigantea* begins to be a rare one. About Lynn’s Canal (lat. 58° N.), the latter species ceases, while from about 53° or 54° N. lat. to north of Sitka, *Cupressus nutkaensis* is a large, handsome, and abundant tree. Here it attains a size equalling that of *Thuja gigantea*, as seen towards the south, and how large that is may be guessed when I mention that in a rich river bottom I measured a *Thuja* which was 45 feet in circumference at the base, and nearly 250 feet in height. This was in the Nittinat River, in Vancouver Island (see my paper “Das Innere der Vancouver Insel,” with map of our explorations, in Petermann’s “Geographische Mittheilungen,” heft. 1., u. iii., 1869, &c.); but I have notes from various friends of mine in different parts of the country, of others which they had measured in the damp forests of *Abies Douglasii*, in the region to the west of the Cascade range in British Columbia, almost if not quite as large.

*Thuja gigantea* is, among the trees on the north-west coast, the Indian’s best friend, for out of its wood and bark he manufactures endless articles of domestic, hunting, fishing, and warlike economy (see the paper on “*Thuja*, &c.” already mentioned, “Trans. Bot. Soc. Edin.” vol. ix., pp. 358—378). Most of their canoes are hollowed out of it, at least in Vancouver Island; and the case quoted by Mr. Murray in the “Pinetum,” from one of my letters, where a canoe was made out of *Cupressus nutkaensis*, in Vancouver, was quite an exception, and indeed the canoe was probably traded from some of the northern tribes, and not of Vancouver manufacture at all. The Indian ropes are also very commonly twisted out of its bark. The tree which I took for *Thuja plicata*, and out of which I happened to see the Indians, just at the time I wrote the letter quoted, twisting ropes, I believe, from after investigation, to have been only a stunted form of *T. gigantea*, and that *T. plicata* is not a separate species, but, for reasons which I have given in another place, and cannot now again repeat, is, indeed, only a variety of *T. gigantea*. North of lat. 53° *Cupressus nutkaensis* takes the place of *Thuja gigantea*, and is applied by the Indians to all the useful purposes of *T. gigantea*, and to some others in addition. For instance, at the Matlakatlah Mission on the coast of British Columbia, in about lat. 54° N., where there are fine groves of it, it is sawn into lumber and sent to Victoria, where it meets a ready sale among the cabinet makers, as it takes a fine polish, and works beautifully. Most of the prettily polished discs and little cylinders used by the Indians in gambling are made either from this wood or from that of *Acer macrophyllum*. It is also valuable for ship or boat building. Sir Edward Belcher, when on the north-west coast, in H.M.S. Sulphur, built a boat at Sitka of this wood, as I am informed by Staff-Commander George, R.N., at that time one of the officers of the Sulphur. In 1864, I noticed several planks of it on board H.M.’s gunboat Grappler, and on inquiring what use they were put to, I was informed by Commander Edmund H. Verney, that he found it the best wood on the whole north-west coast for repairing boats with. A polished specimen, which he presented to the botanical museum in Edinburgh, has been frequently admired for its fine grain. The wood is whitish, but in its fresh state is yellow, hence the name “Yellow Cypress” applied to it. It is light, tough, durable, and easily worked. The property of durability it shares with *Thuja gigantea*, and in addition it has a pleasant fragrance. On this account the Russians about Sitka used to call it *dushnik* or “scented wood.” It was absolutely at one time exported to China, and returned to us marked with Chinese characters, which warranted it as “real Chinese camphor wood,” puissant for many purposes, and a sovereign remedy against moths in drawers! In repairing old Fort Simpson, the only log found sound after 21 years’ trial of those used for “underpinning” was a stock of this. Both it and *Thuja gigantea* are very indestructible in the ground; hence the Hudson’s Bay Company,

wherever possible, used the trunks of these trees as pickets for their forts.

A wreck on the beach at Sitka, originally of this timber, was, I am informed by Mr. W. H. Dall, at present in charge of some coast exploration of Alaska for the United States Government, found, 32 years after, "as sound as the day it was built; even the iron bolts were not corroded." It would, equally with *Thuja gigantea* and *Libocedrus decurrens*, make a handsome lawn tree. The latter, however, is a wretchedly poor timber tree, and neither it nor *C. nutkaensis* is, in my opinion, so graceful in appearance as my favourite *T. gigantea*, which I am surprised has not been more extensively planted in this country.—*Robert Brown, in Gardeners' Chronicle.*

### PLANTING TREES FOR POSTERITY.

LITERAL TRANSLATION IN VERSE FROM THE POETIC FABLE OF  
LA FONTAINE.

THE readers of THE GARDEN (Jan. 11th) must have been much charmed with La Fontaine's charmingly poetic fable on this subject, and must have thanked William Cobbett (who was a writer on trees and gardens as well as politics) for his very close and elegant prose translation of it. Although the rustic politician very justly observes that to attempt a translation in verse would be like an attempt to make a thing resemble a rainbow, and pronounces La Fontaine's lines absolutely inimitable, which is the simple fact, still, after reading the delightful little poem in question, in its own French, readers of THE GARDEN might like to see it in the best English verse that I can supply.

#### THE OCTOGENARIAN TREE-PLANTER AND HIS YOUNG CRITICS.

(A FABLE TRANSLATED FROM LA FONTAINE.)

A MAN of eighty once was planting trees;—  
Three youths passed near, with many a glib word;  
"Build, old men might," cried they, "but plant! that was absurd!"  
Asked one, "Are you a lunatic, sir, if you please,  
That you are planting Oaks and Elms like these?  
To reap results from planting such a park,  
You should live longer than a patriarch.  
Then why," they urged, "fill your last days of life,  
With toils, whose fruits you ne'er can hope to see?  
Think of the past, of thy long mortal strife,  
And dream not of a future, not for thee;  
Bright future visions are for such as we."  
"To you, not more than me, such dreams belong,"  
Retorted placidly the aged man;  
"All earthly things have but the briefest span:  
Who knows, of all the human throng,  
Which life-thread will be short, or which be long;  
The cruel Fates,  
Don't go by dates,  
Nor can their secret e'er from them be wrung.  
Sometimes they miss the aged thread, and cut the young.  
Life is not always safest with the strongest;  
We cannot then,  
By mortal ken,  
Tell who shall see earth's bright blue sky the longest.  
Say! can one single instant e'er ensure,  
That for one other, life may still endure?  
My grandchildren beneath these trees may play,  
In the cool shade, on many a sultry day.  
Do you forbid them, to the sage,  
Simply on the score of age,  
And that, forsooth, he's not a boy,  
To plant, that others may enjoy?  
*Such* work yields fruit without delay,  
To garner in my heart to-day;  
May be, to taste to-morrow, too;  
May be in days not spared to you.  
Who knows the things in Time's dark womb?  
I, perhaps, may sit upon *your* tomb—  
To watch the blushing dawn of some bright morning;  
And so, good friends, let young and old take warning."  
He spoke aright,  
In the sinking light,  
Of that autumn night.

One of the three, upon a long voyage bound,  
Was, even in the port, nuttiacly drowned;  
And one—ambitious—wishing fame to gain,  
While soldiering, by a chance shot was slain.  
The other paid to death his fatal tax,  
By falling from a tree,  
(As though 'twere doomed to be)  
That he was marking for the woodman's axe.

The old man o'er their gravestone grieving bent,  
And made these lines their lasting monument.

AN OCCASIONAL CONTRIBUTOR.

### ESTABLISHMENT OF THE MISTLETOE IN IRELAND.

As this is a good season in which to attempt the establishment of the Mistletoe, where, from its scarcity or other causes, this may be desired, Dr. Moore's account of propagating the plant at Glasnevin may be useful to some of our readers. About thirty years ago (says Dr. Moore) the only Mistletoe plants in Ireland with which I was acquainted were three: one at the College Botanic Garden, Ball's Bridge; another, recorded by the late Dr. Wade, which he saw growing on a Crab-apple tree that had been imported from England—probably the same as that mentioned by Ruttly, in his "History of Dublin," as growing near Island Bridge; and some old plants of it in the garden of Mr. Thomas Acton, Westaston, County Wicklow. These had all been artificially propagated, as the Mistletoe is not a native of either Ireland or Scotland. At that period the late Dr. Whately, Archbishop of Dublin, who was so enthusiastically fond of everything connected with vegetable physiology, became aware of the scarcity of Mistletoe in Ireland, and brought with him from England a quantity of the berries or seeds, part of which he gave to me to try my hand at cultivating, and kept a portion himself for a similar purpose. It may here suffice to state that we both succeeded in getting plants to grow from those seeds, and that now there are many plants in various parts of the country. At Glasnevin there are at least a couple dozen bunches of Mistletoe, growing on six different kinds of trees; but we have not yet been able to get any established on Conifers, though I have seen Mistletoe growing abundantly on Pine trees near Darmstadt in Germany. The seeds of the Mistletoe are surrounded with a white, pulpy, viscous matter, which causes them to adhere to the boles and branches of the trees on which they grow naturally, and which is most essential in aiding their artificial culture. It is only necessary to take the ripe seeds and press them with the forefinger and thumb against any smooth, healthy part of the bark of the bole or branch of an Apple, Pear, Thorn, Lime, or Mountain Ash tree, or even a Rose bush. In performing the operation, care should be taken to avoid rough, hardened parts of the bark, or chinks, and also not to cut the bark in order to place the seeds in the cut, which is so frequently done by those who are inexperienced in the matter. The viscous, gelatinous substance soon becomes hardened over the seeds, and binds them firmly to the points of attachment without the aid of any ligature. About a month or so after the time the seeds are placed on the trees, they begin to swell, and soon afterwards push out one or two rootlets, as the case may be, divergent from the point of attachment. They are slightly concave at their apex, and recurve backwards to seek the supporting body, which on reaching they adhere to like suckers. The other ends of these rootlets, being still adherent to the seed, form at this period of their growth a bow or irregular semicircle; the ends so attached soon afterwards leave the seed, grow erect, and become the plumules. During this process the sucker-like root which has rested on the surface is gradually pushing its way through the bark until it reaches the albumen, where it feeds and nourishes the plumule, while the latter continues to elongate. These plants do not appear to have the power of penetrating farther into the woody system of the trees on which they prey than the albuminous wood, between which and the bast layer of the bark they continue ever afterwards to feed. Many of them, however, send out from the first point of attachment suckers, parallel to the axis of the supporting trees, which at some considerable distance burst through the bark and extend themselves into branches—a circumstance which was noticed long ago by Griffiths and others.

### NOTES AND QUESTIONS ON TREES AND SHRUBS.

**Tree Heights.**—Can any of your readers tell me the greatest height that trees attain in the United Kingdom? I remember a Spruce Fir in Studley Royal Park, Yorkshire, which was said to be 135 feet high. Do Poplars or Silver Firs ever exceed this?—*J. H. W. T., Belmont, Carlisle.*

**Old False Acacia.**—I am desirous of knowing whether the Acacia (Robinia Pseud Acacia), the oldest in Europe, formerly standing in the Jardin des Plantes is still in existence; and if so, its present height and girth. Will any of your correspondents favour me with this information?—*JOHN W. FORD.*

**Ailantus odour.**—The objection as to the loathsome smell of the *Ailantus* (see p. 116) is rather too far-fetched. The noble specimen of it to which I referred last week never gave us any inconvenience as to smell, though garden seeds were continually under its fine long foliage, and in fine weather some of the family daily availed themselves of its agreeable shade.—*D. CANNINGHAM.* [In warm countries, where the *Ailantus* flowers freely, we have noticed a disagreeable odour.]

**Sequoia.**—Many years ago, when this great tree was discovered in California, it was thought to be a new genus, and was named in America *Washingtonia*, and in England *Wellingtonia*. Eminent botanists subsequently discovered that it was not a new genus, but belonged to the genus *Sequoia*. The Americans gave up their name, and the last mentioned was generally adopted. But we still adhere to the wrong name.

## GARDEN DESTROYERS.

## ROSE SAWFLY.

TENTHREDO (EMPHYTUS) CINCTA.

Rose growers occasionally suffer from the operations of the larva of a sawfly, which lives in the interior of the shoots or branches of the Rose tree. We received some time ago numerous specimens from Kirkcudbrightshire, where they have often spoiled many a charming bouquet. The extremity of the shoot is first seen to languish, then it fades and withers. By-and-by the leaves below the bud droop in like manner in succession, one after another, beginning with those nearest the bud. The explanation of this is that the female of a sawfly, named *Emphytus cincta*, lays its eggs in a little chink, which it cuts in the young shoots while they are still herbaceous. The young grubs, as soon as they are hatched, work into the interior of the twig, eating towards the pith, in devouring which they spend the rest of their larval life, and they eat their way downwards, head foremost of course, so that the terminal shoot feels the effect of their presence first, and as the grub descends, each leaf suffers as it reaches the part of the pith connected therewith, until it

Rose Sawfly.

gets below the leaves quite into the ligneous part of the branch, when there are no longer any external symptoms to reveal its presence, except perhaps that the whole branch is somewhat languishing, or may give way, being broken across by a gale of wind at the weakened part. Sometimes several individuals may be found at intervals one above the other in the same stem.

The larva in its earliest stage is faint greenish grey. After its first change of skin, the green on the back becomes darker and blacker, with a velvety sheen of colour in certain lights. There is a pale line along the side, bordering the green, which is darkest next that line, and the lower half of the body is pale yellowish green or greenish grey, with a slightly darker shade on the middle segments near the tracheae. The head is pale yellowish green, with brown mouth, and black brown eyes. The possession of eyes, notwithstanding that it lives in the dark interior of the stem (a situation in which other insects often have them absent), may be accounted for by the universality of that character in the sawflies—a character which is the easiest token by which to distinguish the caterpillar of a sawfly from the caterpillar of a butterfly or moth; that of the sawfly always having eyes, that of the butterflies or moths never. There are other very important differences between the larvæ of these two orders, such as the head of the sawfly larva being rounded like a button, instead of continuous with the body, as in the Lepidopterous larvæ, and having always more than 16 (18 to

22) feet or substitutes for feet, while the Lepidopterous larvæ never have more than 16. But as to the feet it is often a little troublesome to count them, and as to the head the degree of roundness varies, while a glance will at once tell whether it has eyes or not, the eyes being little round dark specks standing conspicuous on its temples. It passes into the chrysalis in the stem, and spins a slight cocoon of white silk. The perfect sawfly is about four lines in length, somewhat elongate, black, with the legs ferruginous and a white band across the black abdomen. This white band, however, is sometimes more or less absent. We do not know whether it has been quite ascertained whether the transformations take place rapidly or slowly. This is of some importance, as, if they take place rapidly, there must be two broods in the year, for Boisduval records that the perfect female insect lays her eggs in the end of April or beginning of May, that he had young larvæ in May, and that some of his insects came out in May; while we had on the 5th of October last good sized larvæ not gone into chrysalis. If Boisduval's larvæ which were young in May, were of the same brood that came out in May, the transformation must have been very rapid; we rather incline to believe that it must be slow, and that the larva passes the summer in feeding and the winter in the chrysalis. Perhaps some of our readers may be able to supply us with information on this point.

The proper remedy for this species is to cut off the Rose shoots sufficiently far down, as soon as the buds begin to show symptoms of fading, and then to burn them. A. M.

## THE KITCHEN GARDEN AT DRUMLANRIG.

The kitchen garden is a mile from the castle, and is entirely hidden from it. It is very flat, and I should imagine cold, being but little above the water level. The supply is chiefly required from August to December, and it needs the entire area to meet the demand during these four months. I never saw such breadths of Cauliflowers and Walcheren Broccoli; the latter seemed everywhere. An astonishing quantity of this is grown and snatched from the frost and stored in cellars, pits, or any dark cool place for winter supply. The early London Market Cauliflower is still the favourite. Peas reach to an extraordinary height and luxuriance at Drumlanrig. The *Ne Plus Ultra* is the favourite for the first crop (August), and the Mossy Podded Marrow, a Pea by no means common in the south, a veritable mossy pod, and Lynn's Dwarf Marrow are considered by Mr. Thomson as two of the finest late Peas. Potatoes too are grown in quantity. But perhaps the most striking thing in the kitchen garden was the quantity of salad. Border after border, and frame after frame, were full of most splendid crisp Lettuces. Many of these borders were to be framed over in winter. This plan is much better than moving the Lettuces into frames. The latter checks them, if ever so little, and a Lettuce checked is a Lettuce spoilt. By the former method they are kept on growing, and are crisp as glass. After growing all sorts, Paris White Cos, and All the Year Round are mostly grown for use up to the end of September. Beyond that period no Lettuce can upon the whole equal the Brown Cos. Take the Brown Cos for all in all we shall not easily find its like again.

The principal range of houses is 400 feet long and 18 feet wide, with a span-roof house at right angles at each end. These houses are built in the most substantial manner with hewn stone; the paths are formed of iron gratings, so that they are always clean and dry. One of the end houses is a greenhouse, the other a Camellia house and Orangery. The Orangery and Camellia house is 60 feet long; there is an Orchid house of similar length, a Peach house 100 feet long, and a Vinery 100 feet long. Behind these is another range of span-roofed houses—for Melons 80 feet, Figs 80 feet, Pines 170 feet, propagating house 40 feet. A third range follows of 100 feet for Vines, early Figs 40 feet, *Passiflora edulis* 30 feet, Pinery 30 feet. In the middle of this range comfortable lodgings for eighteen young men are arranged. Then follows a final range of 112 feet for Pine growing, store rooms for pots, soils, manures, Onions, stables, &c. Behind the main

range there is also a range of workshops, seed-rooms, garden offices, carpenter's shops, sheds for potting, &c. In addition to these glass houses, there is about 1,000 feet run of pits and frames here, and another of 800 or more feet over at the flower garden, with quantities of moveable frames to grow and shelter the enormous quantities of plants required for the flower garden.

Everything about Drumlanrig bespeaks good management. Here, for instance, is a house of Camellias and Orange trees, the former already showing blossom (September) and the Oranges looking the pictures of health and cleanliness. They are the best dessert sorts; and these, with a number of Otaheite Oranges in pots, are designed to furnish eatable fruit with leaves attached to them for the dessert. In one of the stoves was a capital collection of fine-foliaged plants, such as *Dracaenas*, *Crotons*, &c., for table decoration; and grand plants of *Eucharis amazonica*, and some of the larger Palms. *Bouvardias* were also grown in quantities for bouquet work, and a back wall of one house was covered with tree-like shoots of that most glorious of all winter-flowering plants—*Euphorbia jacquiniiflora*. In the Orchid houses were many fine specimens in capital health, the whole being backed up with a row of noble Palms, which gave the house a rich and fully furnished appearance.

As regards Pine-apples, it is impossible that plants could be cleaner, more robust, or healthy, or of "shows" more regular and deeply pipped, or of fruit more regularly swelled or ripened with a richer flavour or more delicious aroma than those grown here. The majority of Pines are fruited here within eighteen months of suckerhood, and some in less time. This, too, is not done by dozens, but by hundreds. House after house of fruiting plants, pit after pit of succession plants—are all alike good. There is no mystery here in reference to Pine growing. Cleanliness, liberal culture, care, skill, and keeping the roots pegging away and always in health, seem about the sum of the matter. Forethought is also needed to start the plants at the right time. I have never before seen such large fruit on relatively such small plants; not that the plants are small, but the fruit is large in proportion. Every leaf is tributary to the sturdiness of the stem, the stoutness of the stalk, or the height or diameter of the fully-swelled fruit. About one-half of the stock consists of Queens, and the other half of smooth-leaved Cayennes, with a few Charlotte Rothschilds and Prince Alberts.

The Vineries are equally well managed, the whole of them bearing the impress of the most skilful and successful treatment. The extraordinary excellence of the Sealife Black and other Grapes, as seen at Drumlanrig in September last, has been remarked upon in several journals. But the greatest triumph in Vine growing I have ever seen were two noble houses of young Vines, which had only been planted out of 6-inch pots in March 1870. A full crop was taken of supernumerists in 1871. The rods and crops on the permanent Vines this year were quite unprecedented for their age. It was not merely that the wood was so strong, but it was hard as a deer's horn, with hardly a trace of pith to be seen. In the whole of my practice I have never met with two-year-old Vine wood of such strength and solidity. Such Vines would have carried any crop without flinching. Meanwhile, however, a terrible foe entered the gardens unnoticed. A Vine from an English nursery carried with it the *Phylloxera vastatrix* on its roots. It was not long till it found its way to these noble Vines. It spread rapidly, infesting a few, then more, increasing and multiplying by thousands. One Vine, several, then a whole house became infested. The fruit was nearly finished before its full power was developed. It infested the roots and swarmed in the larva state upon the leaves. Every precaution was taken to isolate the house from the others, and thus save the second. These precautions, however, failed. Both these houses of noble Vines have been burned, root and branch. The borders are being removed bodily and fresh borders formed. The houses are to be thoroughly cleansed and deodorised, and a fresh start made with clean Vines. No less radical measures seem strong enough to cope with this terrible foe; cure in bad cases is hopeless, for the insects peel the Vine roots bare of bark, and the Vine immediately begins to droop and die. Neither does there seem

any limit to the power and rapidity of increase of this terrific pest. It seems to rise out of the earth in myriads. The dry soil around the roots becomes alive with it, and it swarms on the under sides of the leaves like bees. Pick off a thousand to-day and there seems two thousand more to-morrow. Mr. Dunn (now of Dalkeith) must have had a mild dose of this pest at Powerscourt to have been enabled to cure and extirpate it by scrubbing the roots with soap and water and replanting the Vines in, if I remember rightly, almost the old borders. Why the Vines at Drumlanrig had their roots skinned, and no dressing could have covered them with new bark. The soil, moreover, especially where it was driest inside the houses, was swarming with the insects. Mr. Thomson has found that the *Phylloxera* does not take to any other plant but the Grape Vine, and that a bath of cold water for forty-eight hours destroys it utterly.

From all I can learn it has not appeared anywhere else in Scotland; I have, however, heard of its appearance in several parts of England, and also in Ireland. It is known to be ravaging large districts on the continent, and it would be wise to plunge every Vine, come whence it may, into water for forty-eight hours before planting it in our vinerics.

Returning to the forcing houses, I must add a sentence or two on the remarkably successful way in which Figs are grown under glass. They are trained on trellises, somewhat in the way of horizontal Pear trees; the branches being kept thin and closely spurred in. In this way they fruit wonderfully well, and a great many fruit are gathered off a small space. After growing a large collection, the following are considered best, alike for pots and planted out on trellises; viz., Brown Turkey, Harrison's Seedling, Raby Castle, and Grosse Verte.

D. T. FISH.

#### JAPANESE GARDENS.

INTERESTING as are the Japanese from many points of view, there is no branch in which they are more remarkable than in that of gardening. The fine collections of hardy plants introduced to Britain during the past dozen years sufficiently attest this, for it should be understood that many of the variegated and other curious forms are not such as "occur in nature," so to say, but such as have been carefully grown in Japanese gardens for ages. Even the literature of gardening would seem to be advanced to a high degree among the Japanese. When visiting Mr. Hogg in New York in 1870, we saw various remarkably well illustrated books on Japanese horticulture which that gentleman had brought from Japan. One was a book half a century old, exclusively devoted to variegated plants, and in it were figures of all variegated Japanese shrubs, which have been among the most admired novelties introduced to our gardens of late years. We shall, however, allow Mr. Fortune, the celebrated traveller, and who, as a gardener, is peculiarly fitted to speak on Japanese gardening, to say something on the subject.

One marked feature of the people, both high and low, is a love for flowers. Almost every house which has any pretension to respectability has a flower-garden in the rear, oftentimes indeed small, but neatly arranged; this adds greatly to the comfort and happiness of the family. As the lower parts of the Japanese houses and shops are open both before and behind, I had peeps of the pretty little gardens as I passed along the streets; and wherever I observed one better than the rest I did not fail to pay it a visit. Everywhere the inhabitants received me most politely, and permitted me to examine their pet flowers and dwarf trees. Many of these places are exceedingly small, some not much larger than a good-sized dining-room; but the surface is rendered varied and pleasing by means of little mounds of turf, on which are planted dwarf trees kept clipped into fancy forms, and by miniature lakes, in which gold and silver fish and tortoises disport themselves. It is quite refreshing to the eye to look out from the houses upon these gardens. The plants generally met with in them were the following:—*Cyca revoluta*, *Azaleas*, the pretty little dwarf variegated Bamboo introduced by me into England from China, Pines, Junipers, *Taxus*, *Podocarpus*, *Rhapis flabelliformis*, and some Ferns. These gardens may be called the gardens of the respectable working classes.

Japanese gentlemen in Nagasaki, whose wealth enables them to follow out their favourite pursuits more extensively, have another class of gardens. These, although small according to our ideas, are still considerably larger than those of the working classes; many of

SCENE IN A JAPANESE GARDEN.

them are about a quarter of an acre in extent. They are generally turfed over; and, like the smaller ones, they are laid out with an undulating surface, some parts being formed into little mounds, while others are converted into lakes. In several of these places I met with Azaleas of extraordinary size—much larger than I have ever seen in China, or in any other part of the world, the London exhibitions not excepted. One I measured was no less than 40 feet in circumference! These plants are kept neatly nipped and clipped into a fine round form, perfectly flat upon the top, and look like dining-room tables. They must be gorgeous objects when in flower. *Fargium grande*, and many other variegated plants still undescribed, were met with in these gardens, in addition to those I have named as being favourites with the lower orders.

## THE KITCHEN GARDEN.

### HINTS ON VEGETABLE CULTURE.

It will be generally admitted, I think, that there is no comparison between the crispness and flavour of vegetables grown quickly on land well manured and cultivated and the same kinds of vegetables stunted and starved on a poor, hungry, badly managed soil. Rapid growth in nearly all our culinary vegetables is essential to mild flavour, and next to a genial climate the manure supply is the most important. I am of opinion that a more extended use of artificial manure, such as guano and superphosphates, might be made with advantage. I do not, however, wish to be understood as recommending artificial fertilisers in preference to home-made manure, but only as aids in special cases; such as pushing on crops of early Turnips, Cauliflowers, &c., in ungenial seasons, or when from any cause there may be a scarcity of stable dung. The latter will of course beat all artificial fertilisers in the long run. But apropos of the manure supply, the great problem that now lies uppermost for solution, not only in our towns and villages, but also in every gentleman's country house is the "sewage question." There is a vast waste going on in every country mansion, which, if it could be utilized, would go a long way towards growing the supply of vegetables. If all the waste water from the laundry and other departments of a large establishment (highly charged with manurial matters in a liquid form) could be run into a tank in the kitchen garden, covered but ventilated, and the contents pumped up as required, what an opportunity would be given for increasing the value of our crops. Would it not be better to utilise it thus, than to run it into the lake to poison the fishes, or into some stagnant ditch to pollute the atmosphere?

I am aware that this question is beset with difficulties (the greatest of which perhaps is the apathy and prejudice of those more immediately concerned); but in many places the difficulties would not be insurmountable. In the drainage schemes of new mansions the thing might be carried out satisfactorily. There is no better deodoriser than fresh earth, or at least none so generally and readily available, and with a constantly increasing population, and a diminishing surface available for cultivation, it will ultimately be universally recognised that all waste matter must be utilised. Another important point in the production of good vegetables is the deep stirring of the soil. I can easily believe that much mischief may and probably has been done by injudicious subsoiling or trenching, by bringing up too much of the poor, hungry subsoil to the surface at once, more in fact than could be assimilated, or in any way rendered suitable for the full development of plant-life, but any man practically acquainted with the subject would hardly commit such an error. To deepen and improve poor, hungry land must be a work of time, and must be done with judgment, and be accompanied with liberal applications of manure, and if necessary deep draining should precede it. If treated well the land will respond in a liberal manner. The earth is man's great storehouse, but some judgment is required in extracting its treasures. Deep cultivation and plenty of manure are the only safeguards against adverse seasons. And if in addition to these we had the command of the sewage that is now in too many instances worse than wasted, to encourage our moisture-loving crops, an acre of land would produce double what it does under ordinary cropping, and we should not hear the complaint that Lettuces, Cauliflowers, Celery, &c.,

bolt before they are fit for use. When plants are supplied with sufficient food, and experience no check, their reproductive organs are more slowly developed, but when a plant is threatened by death from starvation (which generally happens on poor, hungry, badly cultivated land in dry seasons), its principal efforts seem directed towards rushing into flower, and so perpetuating itself by producing seed. As regards the vegetable kingdom this appears to be the general law of nature, and we take advantage of this, when, in order to induce a plant to flower, we starve it in a small pot, or for a time withhold water; this is also exhibited by the rapid way in which weeds run to seed in poor, whilst in good soils they attain an amazing development.

E. HOBDAY.

**Early Potatoes.**—In your number of November 16th, 1872, I find an interesting account of a way to raise early Potatoes cheaply and simply with the aid of "Frigi domo" as a covering or protector. Can you kindly inform me whether it is found to answer the purpose effectively? I should require the Frigi domo to be about 7 or 8 feet wide and 6 or 8 yards in length? W. [There is no doubt that the Frigi domo and frame plan of growing early Potatoes is a good one, for the same reason that Peaches can be grown on a south wall if shaded from frost when they cannot be grown anywhere else. Your correspondent must carry the plan out intelligently, however, as I have described, *i.e.*, he must economise to the utmost the sun's heat. Frigi domo will exclude about 6° or 8° of frost when dry. I have adopted this plan myself, and when I was at Drumlanrig with the late Mr. McIntosh we had hundreds of feet of such frames, only using wooden shutters instead of Frigi domo. They are, however, heavy, cumbersome, and expensive; 3 feet of leaves instead of drainage for bottom heat would be an advantage where they can be had.—J. S. W.]

**Manuring.**—A few days ago I visited a neighbour of mine—a gardener in a large private establishment, and when walking through the grounds of which he had charge, he remarked that a border which his men were manuring was rather poor, and that he was giving it a good dressing—a good barrowful of manure to every 9 square feet or so! I invited him to step into my place, in which my men were just doing the same thing on a border from which I had taken a crop of Radishes, Hyacinths, Kidney Beans, Gherkins, and Cabbage Plants, all during the past year, and which I was now preparing for Cauliflower. He did so, and the amount of manure I was applying astonished him. He said I was ruining my ground by manuring so heavily. I told him I could not take five crops off one piece of ground in twelve months with only a single application such as he called a "good dressing," whereas, by my system of manuring, I could do so with impunity. My border is 13 feet wide and 109 feet long; it is divided into 4 feet wide beds, with foot wide alleys between them, as indicated for the Cabbage plants. On each of these beds four good barrowfuls of manure are wheeled, so that, on the whole space, I had eighty-eight such heaps. By this means I can crop heavily and in quick succession, manuring only once in twelve months, and merely loosening or pointing over the soil for each successive crop. I manure heavily and crop heavily. If I manured lightly and cropped heavily, in two years my land would almost be past recovery. I may add that the Hyacinths are grown for the purpose of supplying cut bloom.—A SURREY MARKET GARDENER.

### NOTES AND QUESTIONS ON THE KITCHEN GARDEN.

**Cabbage from Buds.**—The *Pacific Rural Press* says: "Take a large head of Cabbage, strip off the outer leaves, and slip off the buds found at the base of the leaves. Take these buds and simply set them in rich earth. The result will be a fine growth of Cabbage plants, with heads larger and sounder than can be raised in the ordinary way."

**Paraffin and Peas.**—At this season of the year it may be of interest to many of our readers to know that before sowing their garden Peas if they mix about a table-spoonful of paraffin with a quart of Peas, turning them about so that all may get to taste of it, not a mouse will touch one of them, and the Peas will not be injured in the least by the paraffin.

**The Late and Early Rose Potatoes.**—The Late Rose is highly spoken of by American growers, who appear to have thoroughly tested it. Of the Early Rose, that excellent paper, the *Albany Country Gentleman*, says, "It has, in the short space of five years, been tested in almost every locality in our country, under the greatest possible diversity of soil, culture, and climate, resulting in such complete and uniform success as to win the appellation of being 'the Potato for the million.'"

**A Fact for Broccoli Growers.**—Our first sowing of Snow's Broccoli was made on the 16th of March, and the plants were finally planted out in the first week in June. The last sowing was made on the 6th of May; its produce was planted out on the 26th of July, and strange to say, the latest was fit for cutting the first, thus showing that only one sowing is needed instead of three or four, as teachers of such matters tell us.—STAMFORDIAN.

THE GARDEN IN THE HOUSE.

ORCHIDS IN DWELLING ROOMS.

It is not sufficiently known to growers of Orchids how very long many of these plants will remain in flower, if they are brought into the drawing-room immediately after the blossom is expanded; while if allowed to remain in the damp air of the Orchid-house, they would soon lose their flowers. The reason is obvious to all who are acquainted with the habitats of these most lovely of all indoor plants. A great many of the finest genera—especially those from the New World—belong to regions which have alternately moist and dry seasons, each lasting many months. During the rainy period the pseudo-bulbs and leaves are formed, whilst in the succeeding dry season the flower-stems and flowers are thrown up from the completed bulbs. If, therefore, we remove the plants into the dry air of a dwelling-room, the conditions required by nature are fulfilled. Some of the noblest specimens will thus last in the most perfect state of bloom for many weeks and even for three or four months. Groups of lovely flowers have graced my library and drawing-room during the whole year—*Lycastes*, *Cattleyas*, *Laelias*, *Zygopetalums*, *Odontoglots*, *Oncids*, *Trichopilias*, *Miltonias*, *Maxillarias*, *Pleiones*, *Cypripediums*, &c., and at the present date (3rd February) the following are in the greatest perfection, viz.,—*Miltonia spectabilis* (14th week) *M. Morelliana*, *M. Clewesii*, *Pleione lagenaria*, *Odontoglossum nebulosum candidum*, *O. grande*, *Zygopetalum crinitum*, a grand spike; *Cypripedium insigne* and several others having had their day have just been removed. *Vanda teres* lasted 17 weeks in perfection. They seem also not to suffer from a low temperature, 38° and 40° during the night at present. Moist air and sunshine, even in winter, hasten the decay of the flowers. I have put a bell-glass over some dwarf and delicate specimens, such as the *Pleiones*, which is some protection from dust, as well as from the action of air in rooms much used. It may here be mentioned that if cut flowers of valuable kinds are covered by a bell-glass, they will last in a good state more than three times as long as when they are exposed to the action of air. I should add that the roots of Orchids, whether in pots or oak baskets, require very careful attention. I either moisten or plunge the roots occasionally in tepid water. The above remarks apply more especially to such species as have their roots covered up by the mass of sphagnum and crocks in pots; those whose roots are aerial, being suspended on blocks, of course require the moist air of the Orchid-house.

F. W. COOKE.

Glen Andred.

**Ornamental Pot-covers.**—Messrs. Hooper & Co., of Covent Garden, have sent us a modification of the common expanding pot-cover of which we now give a representation. It differs from the

Ornamental pot-cover.

old and well-known article only in being clad with artificial Ivy, Vines, or other suitable plants. The addition of these makes it much more presentable than it hitherto has been.

NOTES AND QUESTIONS ON THE GARDEN IN THE HOUSE.

**Christmas Flowers in New York.**—At Christmas, New Year, and Easter there is quite a rage for flowers of every description in New York. Prices then rise very high, such as *Camellias*, 50 dollars per 100; *Tuberoses*, 10 dollars per 100, and *Rosebuds*, 5 to 8 dollars. These are trade rates. Consumers have to pay higher—*Camellias*, 1 dollar each; *Roses*, 25 cents; *Tuberoses*, 25 cents; *Carnations*, 15 cents; *Violets*, 4 cents. When the holidays are past, *Camellias* fall to 6 dollars per 100; *Carnations*, 1 dollar; *Roses*, 2 to 3 dollars, and all others in proportion.—*Horticulturist*.

**Lomatia filicifolia.**—This is an elegant greenhouse shrub, of compact habit, bearing numerous finely-cut leaves of good substance, and of a dark fresh green colour. These leaves are admirably adapted as a substitute for Fern, and possess the additional advantage of lasting much longer. I cut a couple of them six weeks ago, and to-day they are as fresh as ever, after having done duty with at least a dozen fresh arrangements of flowers. These leaves are invaluable for button-hole bouquets or for other purposes where durability is desired.—F. W. B.

THE FRUIT GARDEN.

PLANTING.

THE ground has been well prepared; the manure, the soil, the elements which compose them, are all about to work together, to combine, and to act, and the trees are to find for their roots a comfortable bed. Do not be in too great a hurry; let the soil settle down for a month at least, and do not plant until then. Make your arrangements, however, so that the planting may not take place later than the middle of March, but before that date, if convenient. If the soil is not ready by that time, and if the ground is not in proper condition, it will be better to defer planting until autumn. It is possible this may not be agreeable, if you are impatient and eager to begin; but you will find it more prudent. Even though the soil should have sunk during the summer months, do not be uneasy about it; on the contrary, this will be rather the better for the trees which will be planted in it. We know very well, and you have no doubt often heard it said, that one may plant at any time of the year, and do so successfully; but these unseasonable plantings require precaution, and often a considerable amount of it. To enter into particulars on this subject here would merely swell the size of these notes without enabling us to gain any time by it. We are only speaking, observe, of woody plants, and particularly of fruit-trees.

Well, you have bought and brought home your trees; if your planting is of any extent, it will last for some time, and you must take care that during that time the roots do not suffer from exposure. Put them "by the heels" in a trench near the planting ground, not burying them very deep, but earthing them up so as to cover the necks well. Group your trees according to their kinds and forms; have some care for all these little details, untie your plants bundle by bundle, and carefully place the proper label on each kind. These may appear too minute precautions; but they will, in the first place, facilitate the work, and, in the second, they will prevent your eating one kind of fruit under the impression that you are eating another, and they will also save you from being bewildered in a maze of mistakes which careless labelling is sure to lead to, and which it is not easy to correct afterwards.

In the next place, you have to provide a position for each tree. The ground having been already fully prepared, all you have to do is to make holes just large enough to contain all the roots easily; and, although the soil has been manured, you may throw into the bottom of each hole a little more decomposed manure, and cover it with a few inches of soil. In the meantime, moreover, the trees should have been trimmed—that is, have had the roots pruned a little, and the unsound parts removed. Then dip the roots in water, or, if their size will not allow of this, water them with a rose watering-pot; immediately afterwards cover them with well-pulverised soil.

Arrange the trees with taste and regularity, and do not place them at random, one standing to the right and another to the left. Generally, in order to have two guiding points, a tree is planted at each end of the line. That is one way; but still there is need of great care and a good eye. It is better to use a surer method: lay a cord from one end to the other; as, in digging the holes, the soil is thrown out on each side, the cord does not meet with any obstacle, and shows accurately the proper place for each tree; and, although it may not be so flattering to one's vanity as to be able to do it by the eye alone, it is sure to be correct, and that is the main thing. It is needless to say that two men at least are required to plant a tree—one to hold it in its place, and the other to cover the roots with soil. If you plant wall-trees, let the graft be turned as much as possible towards the wall, so that the wound which was made in cutting off the heel may be sheltered from the sun; these wounds, moreover, are never very pretty things to look at. But, in the first and principal place, arrange the tree so that the spurs which you will have to prune by-and-by may be conveniently placed.

In planting, let the graft always be some inches above the surface, especially in the case of Apples grafted on *Doucin* and *Paradise*, and the colder your soil is the more closely you must look to this. If buried, the graft might root and thus your object would be defeated. The digging and the manuring, and even the space which the roots occupy, will all have raised the ground somewhat; but that is only temporary; a subsidence will gradually take place, so that after some time the tree will be in a hollow, while if you have calculated and made allowance beforehand for the depression which will follow, your tree will settle to just where it ought to be, that is, to the level of the surrounding ground. If the soil is dry, as soon as the planting is finished, water well. In order to complete the work properly, you will, about the end of March, cover the ground about the bottom of the stems with a couple of inches of half-decomposed manure: that which has been already used for hot-beds will be very suitable for this purpose. There is one more operation very simple, and at the same time very beneficial to trees newly planted, and which have

already attained a certain degree of strength; that is to cover the stem and all the branches with a coating of cow-dung, doing this always about the end of March. Trees suffer very much from the sun during the first year after they are planted, and this is an excellent method of protecting them. The cow-dung adheres firmly to the bark; if, however, after heavy rains, it should happen to come off in spots, repeat the operation; it is a necessary one, and even indispensable for wall-trees. We have recommended it for trees that are already mature, but even young trees will be none the worse for it. It is in consequence of slovenly planting and not protecting the trees during the first year, that some persons deny the possibility of succeeding in planting old specimens. It would be well to go a little further and protect the place of union of the stock and scion still better from the heat of the sun by placing before it either a tile, or a board, or some other screen. In the course of the summer, during droughts, water copiously but not often: for trees properly planted and covered about the roots, a weekly watering will be sufficient in dry soils, and two or three per month in cool, moist localities.

After the first year, trees seldom require so much attention; it will be well, however, to give the roots a fresh mulching every spring, after forking in the mulching of the previous year.

Some persons disapprove altogether of the culture of any kind of vegetables in the beds where fruit-trees are planted; but we consider the prohibition too exclusive, especially while the trees are young and their roots do not require a great deal of nutriment. However, in every case we must act with discretion, and not plant anything that will exhaust the soil or remain long in it; but such things as a few salads, Lettuces, early Potatoes, &c., which will always be a nice addition to your crop of fruit.

F. JAMIN.

### FIGS.

THE natural habit of the Fig (which comes to us from the south of Europe) is that of a low-spreading tree. Along the south coast of England, especially about Arundel and Worthing, Fig trees grow and fruit abundantly, planted and treated in the same way as we do our standard Apples. Generally, however, throughout the middle and southern portions of England it is only against walls that Figs can be or are cultivated in the open air; and when sufficient attention is paid to them they succeed tolerably well. It may be remarked that Figs always seem to succeed best in districts bordering on the sea, so that it is to be assumed that moist sea air is agreeable to them. At Cullen House, Banffshire, which is situate on the sea coast, beautiful crops of Figs have been obtained; but this is the most northern locality where we have heard of Figs succeeding. The Fig is by no means a popular or a relished fruit in this country. Some are exceedingly fond of them, whilst others quite as thoroughly detest them. Very few like them at first; they are what is termed sickly, but by degrees, by tasting thoroughly well-ripened fruits, most people become fond of them. There is wonderful variety in their flavour, even when fully and perfectly ripened, and a badly ripened Fig is at all times detestable. The soil most suited for the cultivation of the Fig is that termed calcareous, with a chalky or gravelly subsoil. This is the sort of soil in which they grow in their native country, as well as that about Arundel and Worthing. When cultivated in pots, a soil a little richer must be used. Of the varieties of Figs most suited for cultivation, the following are recommended:—

**White Marseilles or White Genoa.**—Fruit of medium size, roundish, very prominently marked with longitudinal ribs; skin green, changing to a paler green when ripe; flesh whitish or opaline, rich and sweet. This variety is very prolific, and succeeds well as an open standard at Arundel and Worthing, and against walls in the neighbourhood of London and the midland counties. It is well adapted also for cultivation under glass and in pots.

**Brown Turkey, or Lee's Perpetual.**—Fruit of medium size, pyriform; skin brownish red; flesh dull red; a rich variety, very prolific, and one which succeeds well against walls in the south and middle districts, and partially so as an open standard. It is well adapted for cultivation under glass, and it is the variety most commonly to be met with. It forces well, and although not of extra high flavour is one of the safest varieties to cultivate. The finest tree of this variety with which we are acquainted is at Syon House, Brentford.

**Brunswick.**—Fruit large, pyriform, slightly curved; skin greenish yellow, shading off to dark brown on the sunny side. Flesh pale, slightly tinged with pale rose near the centre; when well ripened, rich and luscious. This variety is one held in much repute, and it is a kind everywhere in cultivation; it succeeds well against open walls to the south of London, but only partially so farther north. It does not force so well as the two preceding, but is excellent for a late house. The leaves are deeply cut, and it is a very robust

grower. Castle Kennedy resembles this, but it is a much more shy grower.

**De la Madeleine Angelique.**—Fruit of medium size, round; skin pale straw colour, pubescent; flesh white or opaline, moderately rich. This is frequently confounded with White Marseilles, but it is totally distinct from that variety. This is the earliest variety of Fig, and is worthy of cultivation on that account. It is prolific, and will ripen in the open air. It is not as yet in common cultivation in this country, but it is highly recommended.

**Grosse Monstrueuse de Lipari.**—Fruit large, turbinate; skin brownish red. Flesh dull red, moderately rich. This also is a very early variety, prolific, and one which forces well. It is recommended for cultivation against walls and for early crops.

**Bourjassotte Grise.**—Fruit of medium size, turbinate, almost oblate. Skin of a dull plum colour with a thick bloom. Flesh of a deep dark red colour, thick, rich, and excellent. This is the richest flavoured, and the most constantly good Fig in cultivation, being high flavoured even under the most adverse circumstances. It is recommended especially for pot culture and for cultivation under glass. The largest plant we have ever seen of it is at Carton, the seat of the Duke of Leinster, Maynooth.

**Grosse Verte.**—Fruit very large, obovate. Skin deep green, changing to greenish-yellow when ripe. Flesh deep red, with thick flesh, very rich and excellent. This variety is late, and requires a considerable amount of heat to ripen it thoroughly, otherwise it is apt to crack. It is recommended more especially for pot culture.

**Royal Vineyard.**—Fruit above medium size, of a long pyriform shape; skin reddish-brown, somewhat resembling the Brown Turkey. Flesh dull red, exceedingly rich and excellent. A very prolific and good variety for general cultivation under glass.

**White Ischia.**—Fruit small, roundish, with a long stalk. Skin pale greenish-yellow, tinged with dirty brown. Flesh red, rich, and highly flavoured when well ripened. Immense cropper, and a very useful variety, which will continue bearing fruit and ripening it until after Christmas. Rather variable at times, and requires heat. It is best adapted for pot culture.

**Col di Signora Bianca.**—Fruit large, pyriform, with rather a long neck and very distinctly marked with longitudinal ribs. Skin pale green, changing to almost white when ripe, very thick. Flesh deep red, thick, rich, and syrupy. Very excellent; requires a good deal of heat to ripen thoroughly. Recommended for pot culture.

The above varieties represent all those most worthy of cultivation, whether in the open air, against walls, planted out under glass, or in pots. For simplification they may be classed thus:

For Open-air Standards.—White Marseilles, De la Madeleine, and Brown Turkey.

For Growing against Walls.—Brown Turkey, White Marseilles, Brunswick, De la Madeleine, and Grosse Monstrueuse de Lipari.

For Planting-out under Glass.—Bourjassotte Grise (A I), Royal Vineyard, Brown Turkey, White Marseilles, and De la Madeleine.

For Cultivation in Pots.—De la Madeleine (very early), White Marseilles, Royal Vineyard, Grosse Monstrueuse de Lipari (early), Grosse Verte, Bourjassotte Grise, Col di Signora Bianca, and White Ischia.

Figs are of very easy cultivation. What they delight in whilst growing is plenty of moisture and heat; and to ripen the fruit perfectly they should have the best sunny exposure out of doors or else be grown in an orchard-house.—*New Practical Gardener.*

### NOTES AND QUESTIONS ON THE FRUIT GARDEN.

**Rabbits *v.* Fruit Trees.**—The application of blood to the stems of fruit trees has been under trial for several years, and so far, when well applied, has been successful in repelling rabbits.

**A Cranberry Crop.**—Three thousand bushels were recently picked from 3½ acres of land near Berlin, Wisconsin. From 40 acres on the Carey Marsh, 3,200 barrels were picked, worth 3 dollars per bushel. One cultivator employed 1,400 hands this season in picking Cranberries.—*Horticulturist.*

**Large Pears.**—It appears to be proved that Pear-growers are able to produce fruits of abnormal size by supporting the growing Pear from underneath, instead of allowing it to hang on the peduncle. M. Decaisne has seen Poires de Livre 2½ lbs., Moreceau 1½ lbs., and a Chaumontel of 1½ lb. weight, produced in this way.

**Keeping Apples.**—In America, where the cold is so severe in winter, the *Tribune* speaks thus of keeping fruit: The essential conditions for preserving Apples or other fruits in the most perfect state for as long a time as possible, are, 1. Coolness and evenness of temperature. A uniform temperature of 36° is the most favourable, and from this there should be no greater variation than 4°. After steady cold weather sets in, this degree of coolness is easily maintained; but, prior to that season, it requires considerable attention. Whenever the temperature in the fruit house rises above 10° in the day time, all ventilators have to be closed until evening, when they are opened again and left so during the night. 2. Dryness of the atmosphere without desiccation. Exclusion of light is desirable, but not absolutely necessary.

GARDEN PORTRAIT GALLERY.

JOHN PARKINSON.

JOHN PARKINSON, whose portrait, a facsimile of that found in one of his works, is here given, was one of our earlier botanical and horticultural writers. Comparatively little is known of him, the account given of him by Pulteney being extremely meagre. From it, however, we learn that he was bred an apothecary and lived in London; that he was contemporary with Gerarde and Lobel during the latter part of their lives, and survived Johnson, the editor of Gerarde, for several years. His contemporaries speak of him as a man of eminence in his profession, and as possessing a garden (we learn from his "Theatrum Botanicum" that it was situated in Long Acre) which was well stocked with varieties. He was appointed apothecary to James I., and filled the post of "King's Herbarist" to Chas. I. The date of his death is uncertain; his "Theatrum" was published in 1640, when he must have been seventy-three years of age.

This was Parkinson's most important work, and seems to have occupied him many years; during its compilation he encountered many obstacles, one of which, according to Pulteney, was the necessity of having all the figures, although copies of others already published, cut anew for this book. But his earlier work, "Paradisus Terrestris" (of which two editions appeared, from the earlier of which our portrait is taken), is in many respects a more interesting volume, giving us, as it does, a good general view of what English gardening was in the seventeenth century. The plates represent many of the old-fashioned flowers which are now lost to our gardens, such as many of the varieties of Daffodils (of which there were then "almost an hundred sorts"), of Anemones ("or Wind-flowers so pleasant and so delightfome flowers, that the sight of them doth enforce an earnest longing desire in the minde of any one to be a possessor of some of them at the least"), of Tulips ("which are the pride of delight"), and of all kinds of Stocks, Daisies, Violets, Carnations, Primroses, Violets, Marigolds, Bachelor's Buttons, Columbines, and

the like. Indeed, the introductory chapters on "the ordering of the Garden of Pleasure" are delightful reading, not only from their quaint phraseology, but for the genuine love of his subject which the author manifests throughout. His eulogies upon each plant as it comes under notice are most delightful; but his favourites appear to have been flowers of the Pink tribe. "What shall I say," he asks, "to the Queen of delight and of flowers, Carnations and Gilleflowers, whose bravery, variety, and sweete smell joyned together, tyeth every one's affection, with

great earnestnesse, both to like and to have them?" Of these no less than fifty are enumerated, under names, many of which sound somewhat strange to modern ears, as the Hulo, the Savadge, the Chrystall, the Gran Père, the Cambersine, the Granade, the lustie Gallant, the "Fair Maid of Kent or Ruffling Robin," and so on. In our portrait he has in his hand the scarlet Lychnis (L. Chaledonica) then known as "None-such," or "Flower of Bristow," or "Constantinople," of which a double variety was at that time in cultivation, a "glorious flower as rare as it is beautifull," which, "for his bravery doth well deserve a master of account that will take care to keepe and preserve it." We are tempted to go on quoting from the delightful old book, but the want of space compels us to bring our brief remarks to a close.

**Betel Nut.**—There is a fascination in the Betel nut more extraordinary than in the tobacco passion. The consumption of the latter in chewing alone, in the United States, is a modern phenomenon. An inveterate chewer may have moral resolution enough to break off the habit, though it rarely happens that an effort is made to do so, as an apology is found for continuing a practice that is positively destroying the

foundations of health. Once addicted to chewing tobacco, to abandon it is an achievement few have the happiness to perform, notwithstanding the melancholy mortality of men in the meridian of life who are constantly being destroyed by the subtle influence of that strange plant on the nervous system. Thus sudden palsy of the heart, palsy of a limb, palsy of one-half the tongue, and even instantaneous death, are traceable by physicians to excessive use of tobacco. But the vice of Betel nut chewing is still more remarkable. When the habit is established there seems

John Parkinson.

no retreat. The victim wears out his teeth, gums, and digestion, and dies with an unsatisfied longing for another quid. Betel nut trees thrive in most parts of tropical India, the Indian Archipelago, and the Philippine Islands. They grow up gracefully about 30 feet, rarely more than 8 inches in diameter. It is an *Arcea catechu*. Penang is the universal name of the nut in those places where it is produced; hence Pulo Penang means a Betel nut island. At six years of age, the tree commences bearing nuts of the size of a small pullet's egg, of a bright yellow colour, enclosed in a husk similar to that of the cocoa-nut; within is a spherical nut, very much like a nutmeg. Broken, a bit of it is wrapped up with a piece of unslaked lime in a peculiar leaf, the *Siri betelpiper*, extensively cultivated for that purpose. The gums and mucous membrane of the mouth are quickly stained a brick-red; the teeth crumble to a level with the gums; and in that condition an inveterate Betel-chewer is wretched without a supply. There are large plantations of Betel nut trees in Java to meet the demand for home consumption and in distant provinces. To augment the pleasure, those who can afford it add tobacco to the lime.

## SOILS, MANURES, &c.

### APPLICATION OF MINERAL MANURE TO HORTICULTURE.

MANY horticulturists and writers on plants believe that it is impossible to grow plants in a sterile soil by means of artificial food composed of mineral substances dissolved in water. My aim is to prove by experiments, the results of which I shall presently describe, that:—(1.) Nitrates or nitrites are naturally formed in soil containing organic vegetable matter when in contact with air. (2.) That it is possible to feed plants with solutions of mineral compounds suitably prepared, so that the plants receive from these solutions the mineral constituents they require, and may thus grow more vigorously even in pure sand than in the best garden mould.

This opinion was put forth in 1856 by Boussingault while experimenting on the growth of the *Helianthus* (Sunflower). The eminent *savant* then said that the plant assimilates the mineral substances, and need not necessarily be placed in a soil containing decaying organic matter. And this opinion is also confirmed by the experiments of G. Ville, which prove the importance of chemical manures in agriculture. I have utilised the opinions of Boussingault, Millon, and Schenbein on the natural production of the oxygen compounds of nitrogen, and at the same time have somewhat modified them. I first studied the natural conditions of the formation of nitrates in arable soil, without the intervention of ammonia, simply from the elements of air and the reduction of these nitrates by humus. I applied Schenbein's reagent (solution of iodised starch acidulated with sulphuric acid), which strikes a blue colour in the presence of nitrates. By the aid of this reagent I ascertained the following facts:—

When arable soil or garden mould is well washed in a displacing apparatus with pure distilled water, that fluid always exhibits the presence of nitrites. It is, however, necessary to use—for the complete removal of the nitrites from the soil—about twelve times the quantity by weight of distilled water to the weight of the soil experimented upon. The soil thus treated having been again dried, yields, after a short time, nitrites, as indicated by Schenbein's test in the water employed a second time for exhausting the soil. Sandy soils, and all those which do not effervesce when treated with acids, do not recover nitrites after being dried unless carbonate of lime is added, and the soil then moistened with water and again dried, and lastly washed with distilled water, which then exhibits the reaction for nitrites.

When a solution of the nitrates of potassa and ammonia at 5.1000 is made to pass through the arable soil or garden-mould previously well washed with water, the soils being placed in a displacement apparatus, it will be found (as I also ascertained) that the nitrates are retained in the soil. 2½ lbs. of the soils—which require to be moistened with about half their weight of water—retain about four-fifths of the soluble salts contained in the first litre (1 7-10ths of a pint) of the saline solution at 5.1000, which is poured on to the soils. Nitrate of ammonia is retained by the soil in larger proportion than nitrate of potassa. The alkaline nitrates are in 24 hours reduced to nitrites when in contact with dead leaves, straw, or humus. The reduction is so marked that when dead leaves are washed with distilled water, the leaves distinctly exhibit, with Schenbein's reagent, the presence of nitrites, due to the nitrates naturally present in the well-water of Paris. These facts appear to me to lead to the following conclusions:—

(1.) Soils containing humus and lime determine, while drying,

the combination of the elements of the air, without any intervention of ammonia, so that either nitric or nitrous acids are formed, which are at once fixed by the lime. This explains, not only the sterility of soils void of lime, and of peat bogs, but also the utility of liming the soils.

(2.) The nitrate of ammonia contained in rain-water and in dew (Millon and Schenbein) is retained by the humus in the upper layer of the soil, with the nitrites constantly formed in the well aerated and limed soil, according to the conditions of the atmospheric moisture or dryness.

(3.) This constant formation and renovation of the oxygen compounds of nitrogen in soil containing lime and humus is a fact of great importance, which explains the exceptional fertility of the soil in alternate wet and dry weather, when frequent showers of rain are followed by great heat, as was the case in 1872 (in France, at least). It also, in connection with the great affinity of the humus for soluble salts, more especially ammoniacal, accounts for the accumulation of fertilising principles in fallow lands, and at the same time shows the utility of mechanical operations in the soil, such as ploughing, digging, harrowing, &c., by which means contact with the air is increased and free access of air promoted. I have tried to elucidate these theories by a series of different horticultural experiments, specimens of which I send to the Academy.

I. Comparison between plants grown in sand and in garden mould. The plants placed in sand have been supplied every week, in addition to receiving ordinary water, with a solution of some grains of mineral manure dissolved in water. The plants placed in garden-mould have only had common water. The pots were placed on saucers, in order to prevent loss of soluble salts. I exhibit, as specimens of this experiment, two plants of the *Pelargonium zonale* and two of the *Agave corniculata*, which in April last were all in the same stage of development. The *Pelargonium* grown in the sand is four times as much developed as that grown in the garden-mould, and has been constantly in bloom during the summer; the *Agave* grown in the sand is twice as large as that grown in the garden-mould.

II. Plants grown only in sand: but some watered with common water only, others with the mineral solution, once a week.—I exhibit here, as specimens, several *Arum italicum*, and state that I have, during the summer, made a large number of similar experiments with plants belonging to different natural families, such as *Begonias*, *Tradescantias*, *Veronicas*, &c. The plants grown without the addition of mineral manure are either dead or drooping, while those raised with the addition of that manure have grown magnificently.

III. Plants grown only in garden mould, to some of which only common water has been given; and to others, in addition to that fluid, a quantity of the mineral manure solution has been supplied weekly. As a specimen of the result of this experiment, I exhibit two specimens of *Sedum acre*, the plant which has received weekly 3 grains of the mineral manure solution having grown twice as much as the other.

IV. Plants which have remained for two consecutive years in the same soil in pots. These, as far as they have been treated with my mineral manure, have grown so well that their size is altogether out of proportion with the pots which contain them. As samples, I exhibit an *Aspidistra elatior* and an *Arum esculentum*.

The mineral manure which I use is made up according to the results of elementary analysis of wheat and of farm-yard manure, taking into consideration that the arable soil, containing organic matter, acts constantly as a nitre-bed, and thus fixes the elements of the air in combination. The manure consists of the following ingredients:—

Nitrate of ammonia . . . . .	400 parts.
Nitrate of potassa . . . . .	250 "
Biphosphate of ammonia . . . . .	200 "
Chloride of ammonium . . . . .	50 "
Sulphate of lime (gypsum) . . . . .	60 "
Sulphate of iron . . . . .	40 "
	1,000

The salts should be pulverised separately, and then intimately mixed. I apply this manure in the following manner:—Dissolve 62 grains in a litre (1 7-10ths pint) of water; give to the plants, according to their state of development, every week from 38½ to 975 grains of this solution (equal to from 1½ to 9 grains of the salt in solid state).

Conclusions:—(1.) Plants can be fed by means of artificially-made mineral solutions. (2.) Horticulture may greatly profit by this mode of growing plants, because it renders repotting unnecessary, and because the nature of the soil becomes a matter of entire indifference, provided it offers to the plants a proper and sufficient permeable hold; while, lastly, the plants can be fed at will and when most convenient.—*J. Jeannel, in "Comptes Rendus."*

## THE HOUSEHOLD.

## ORANGES.

THE Orange is undoubtedly our winter fruit *par excellence*, as it is indeed our only fruit when Apples and Pears are going out, and Gooseberries and Cherries have not yet come in. Orange marmalade and Orange brandy are well-known British institutions, but they are made with the Seville or bitter Orange. It is a mistake, however, to suppose that its more luscious sister, the sweet Orange, is only fit to be shown at dessert, or sucked by schoolboys and the pit audience of second-rate theatres. Even in the early winter months, when the Oranges which reach this country are scarcely ripe enough to have any sweetness at all, they can be turned to good account in the preparation of several sweet dishes, most of which present the seldom attained combination of excellence and cheapness. The former quality depends a great deal on the preliminary process of peeling. *Peler à rif*, as it is called in French, consists in removing the whole of the skin, including the thin pellicle which covers the "quarters" of the Orange, then each Orange should be cored as Apples are cored. A very sharp knife should be used, and the corer ought by no means to be blunt. Before peeling an Orange it should be washed clean, and the *zeste*, or yellow rind, should be pared off as thinly as possible, to be used as directed farther on. This process of peeling is of great importance; and need I again repeat in this paper that the cook's hands should be scrupulously clean?

The simplest of all the dishes made with Oranges is a salad which in its primitive form consists of Oranges sliced unpeeled, with some sugar strewed over them, and a dash of brandy or rum. To proceed artistically, the way to make a salad of Oranges would be as follows: Peel *à rif* half a dozen Oranges, cut them in slices a quarter of an inch thick, remove the pips and the pith in the centre of each slice; put them into a deep dish with the juice produced in the process of peeling, and the thin yellow rind of one Orange, strew plenty of powdered loaf sugar over, and keep them covered till wanted. At the time of serving, arrange the slices in a glass dish in a circle, and overlapping each other; add a wineglassful of Cognac or of rum to the syrup left in the other dish, strain the whole over the salad, and serve. Any kind of liqueur, such as Maraschino, Curaçao, &c., may be substituted for the Cognac, or sherry may be used instead. Another form consists in serving the Oranges whole (peeled and cored). They should be kept in this case a little longer with the sugar, and the thin rind of one Orange having been infused in the juice of another with the brandy or liqueur, the whole should be strained over the Oranges piled up on a glass dish.

The next preparation that suggests itself is a

*Compôte* of Oranges, which is made thus. Put a handful of loaf sugar to boil with a gill of water in a saucepan; when it boils add the rind of three Oranges minced finely or cut into very narrow strips. Let the whole boil five minutes, add a liqueur-glass of brandy, and pour the syrup (hot) over half a dozen of whole Oranges, peeled and cored—or cut up in any form you like. The Oranges should be left in a basin with the syrup, till quite cold; then piled up on a dish, and served.

Orange tartlets are made by lining patty pans with sweet short paste; these are filled with uncooked rice, and baked to a light colour; then, the rice being removed, each tartlet is furnished with a small quantity of *compôte* of Oranges, cut up small, made as above. Orange tartlets are usually served cold, but they may be made hot by being put into the oven for a short time, after they have been filled with the *compôte*. The following is another form; the shell of paste is made the same in diameter as the Oranges about to be used; these, after being peeled and cored, are cut into halves lengthwise, and treated with the syrup as above; then half an Orange, with the convex side uppermost, is placed on each tartlet, and a small quantity of the syrup is poured over. This variety of Orange tartlet can be ornamented with candied Cherries, Angelica, pistachio nuts, or almonds—the two last duly blanched of course. A *compôte* of Oranges—with the brandy, and even the thin rind, left out or not, as the case may be—served in conjunction with a pudding of a farinaceous nature, such as rice, tapioca, semolina, &c., or with a custard pudding, is always a welcome sweet with children, and I will venture to say as wholesome as it is welcome.

Oranges can be combined with rice in one dish, and Oranges *au riz meringuées*, homely as some may account the dish to be, is a preparation which will commend itself to parents and guardians, as well as to their charges. The way to proceed is this: Pick and wash a couple of handfuls of rice, put them into a saucepan with a pint of milk or more, a little sugar, and the thin rind of two Oranges; let the whole simmer until the rice is quite done and has absorbed the whole of the milk. Remove the Orange rind, and spread out the rice flat on a dish. When it has cooled, dispose on it a *compôte* of Oranges cut in halves, and pour the juice over; then

beat up to a stiff froth the whites of three or four eggs, with a little powdered sugar; pile up the froth over the rice and Oranges, so as completely to cover them; put the dish into the oven until the top of it is browned slightly, and serve immediately. This dish can be modified in various ways, as *e.g.*, by adding yolks of eggs to the rice before it has cooled, by flavouring it with vanilla, by preparing it with cream as for *riz à l'Impératrice*.

Fritters are too well known a preparation of Oranges to need but a passing notice. The best formula to my mind is that which directs that the pieces of Orange should lie in a marinade of rum and sugar, before being dipped in batter and fried. In the preparation of fritters the peeling process plays an important part.

Jellies, creams, and custards *à l'orange*, being flavoured rather than made with Oranges, do not come within my present purpose; but one variety of Orange jelly I will describe. It is made in the following fashion: Divide two or three Oranges into "quarters," remove with a sharp knife every particle of skin of any sort from each quarter, and cut it in three or four pieces. Make in the usual way a jelly flavoured with Oranges, put into it the pieces of Oranges, and place it on ice to set. This preparation is an agreeable change from the ordinary Orange jelly, and is, so to speak, the first step towards learning to make that delectable dish—a Chartreuse of Oranges. To make this, procure two plain moulds, one exceeding the other in diameter by about 1½ inch. Make an ordinary Orange jelly, pour a little of it into the larger mould, place in it a layer of Orange quarters, freed from every vestige of skin of any kind; pour over them just enough jelly to get a smooth surface. Place the mould on ice for the jelly to set. When it is quite firm put the smaller mould inside the large one, taking care so to place it that the vacant space between the two moulds be of the same width all round. In this vacant space dispose quarters of Oranges prepared as above, filling up the interstices with liquid jelly until the whole space is filled up. Place the mould on ice; whip a pint of cream with half an ounce of isinglass dissolved in milk, and some sweetened Orange juice, which must be added a very little at a time, else the cream will not rise. When the cream is ready, and the jelly set, remove the smaller mould by pouring warm water into it: fill up the inner space with the cream, set the chartreuse on ice for an hour; turn out, and serve.

Those who have mastered the art of boiling sugar can make very pretty dishes with Oranges glazed with sugar boiled *au cassé*; but to enlarge upon this would, I fear, take up too much of your space.—*Queen*.

**Fruiterers' Company.**—The annual banquet of this company took place, as usual, on the 25th ult., at the London Tavern, Mr. R. Broadwater (master) presiding. The *City Press*, in its report of the proceedings, says:—This company, according to ancient custom, has the honour annually to present specimens of fruit to the Lord Mayor for the time being. The origin of this custom, it has been considered, is that the Lord Mayor's meter was formerly entitled to receive a portion or sample from every load of fruit coming into the City. The practice occasioned much controversy between the collector of such samples and the persons bringing in the fruit, until the company arranged that a present should be made to the Lord Mayor annually. In return, the Lord Mayor invites the court and officers of the company to a banquet at the Mansion House. In responding for the drinking of his health, the Lord Mayor said he could not forget that there was a peculiar custom connecting the Fruiterers' Company with the Lord Mayor for the time being. It originated in days when the Lord Mayor was supposed to measure the fruit, the corn, and the coal that came into the City. In these days, as they knew, oddments tumbled out of the baskets of fruit, and the Fruiterers thought it right that the chief measurer, or meter, should have some of them. The Fruiterers, he believed, had legally no control over the carrying, measuring, or clearing of the fruit, but their kindness of heart had continued nevertheless—their kind offerings were an evidence of their respect for the office of chief magistrate, and of their desire, he thought, to maintain that old connection, and thus to cultivate a social amenity which stimulated hospitality on both sides. He rejoiced to think that it was the privilege of the Lord Mayor to invite the Fruiterers' Company to dine with him, and he was sure that no banquet given during his mayoralty in the Egyptian Hall would have a greater interest for him than that of which the Company of Fruiterers would be his guests. He wished a similar custom pervaded the other companies.

**Pine-Apples.**—The island of St. Michael, so justly celebrated for its Oranges, is likely soon to be equally famous for its Pine-Apples. The production at present is not large, but is annually increasing. The "Ocean," steamer, brought 150 last week, which realised at public auction from 10s. to 30s. each.

## WORK FOR THE WEEK.

## PRIVATE GARDENS.

**Flower Garden.**—The replenishment of flower-beds from our reserve stock must now occupy attention; all spring flowering plants may be transplanted with impunity according to convenience. Several of the autumn-sown annuals too may be transplanted from their winter beds to where they are required for blooming, and to fill up vacancies between perennials. Hollyhocks and Foxgloves from last year's sowings should now be transplanted permanently in good rich soil; indeed, a spadeful or two of well-decayed manure mixed with the soil in each hole is an important addition. Ivy, Jasmines, Clematises, Honeysuckles, Roses, Crateguses, Magnolias, and similar plants on walls should be thinned or pruned if necessary, and neatly trained. Roses on pillars should have the dead wood removed, the very long living shoots shortened, and the whole neatly retied to the stakes or pillars. A few Roses in beds and borders may be pruned to induce early blooming, but the general pruning had better be delayed for a short time yet. Suckers and very gross growths may, however, be removed from all, and stakes applied to such as require them. Form edgings of the variegated Queen of the Meadow, Arabis, Cress, Polemonium, Grasses, Daisies, Golden Feverfew, Eranthis radicans, Santolinas, &c. Some of these, such as the Golden Feverfew and Cress are only fit for spring gardening when saved from the previous year's sowings, and to be replaced again in April or May from spring-sown plants which do not so readily run to seed during the summer and autumn months. Various kinds of flower seeds should now be sown for early blooming, but the main crop of hardy annuals is best sown in the first week of April.

**Greenhouse Plants.**—A general potting of these should now take place. Some of the Fuchsias under the stages should be turned out of their pots, have the old soil shaken from their roots, and then repotted in fresh soil in the same sized pots. Do not water them for a time, nor prune them closely until they begin to break. Cuttings of those struck in the autumn, and kept growing since that time, will now be good specimens, as will be also those that were propagated in winter. Of *Lilium auratum* a few of the most forward should be placed in the stove, and on a shelf near the glass, for flowering in May. Be careful in applying water at first; it is the safest to pour it gently round the inside of the pot—not over the whole surface of the soil. Some pots of *L. roseum punctatum*, and alium may also be treated in the same way. No water should be given to such as are still in the greenhouse until their shoots appear. *Tritonia aurea* is now beginning to grow; therefore, such as require shifting should be repotted in a compost of two parts good loam, one of leaf-mould or rotten manure, and some sand. Care must be taken in repotting not to injure the fleshy roots; the stock may, nevertheless, be readily increased by division. The coolest part of the greenhouse is sufficiently warm for them. Plants of *Nerine* should now be repotted and placed in rather a warm, moist temperature, to encourage growth. A compost like that for *Tritonias* suits them perfectly. Of *Convolvulus mauritanicus* the old plants may now be divided, potted in small pots, and kept in the warmest corner of the greenhouse; these plants are particularly suited for suspended baskets, but when grown in pots, and then transferred to the baskets, they form better flowering plants than such as are wholly kept in baskets. A few of the finest *Cyclamen* blooms should now be fertilised, and the plants should be placed on a side shelf; only a few, say half-a-dozen flowers, should be fertilised on one plant, from which all other flowers must be removed as they appear, otherwise the seed will not be so satisfactory. The last shift should be given to *Cinerarias* and *Calceolarias*, using this time a richer compost than that employed for the previous potting. Show and fancy *Pelargoniums* should now have a general shift, and be kept rather close for a few days afterwards; for the old plants shaking them out of their pots, and repotting them in the same sized ones is quite sufficient, provided manure-water be applied when their roots become matted. A too close temperature must be avoided, for the firmer and more stocky the growth is the more likelihood is there of a profusion of bloom. Some of the finest zonal *Pelargoniums* ought to be repotted and placed in gentle heat, to encourage them to form fine specimens for the conservatory.

**Frames.**—The stock of *Pelargoniums* to be used for bedding purposes may now be safely transferred from the various houses and pits to cold frames. Where several plants were put into one pot at lifting time for convenience in storage, they ought now to be separated and potted singly. Any required for yielding cuttings should be kept in some of the fruit-houses "at work" or in a gently heated frame. Autumn cuttings of bedding *Calceolarias* are now growing pretty strongly; their tops should, therefore, be pinched out and used as cuttings. The plants themselves should also be lifted and transplanted farther apart, in a good compost 8 inches

deep, on a firmly-trodden subsoil. *Ageratums*, *Verbenas*, *Salvias*, and several other plants not required for stock, are best treated in a similar manner, because they grow freely, root well, and allow the sashes to be completely removed in the event of fine weather, thus causing a close, stubby growth by the middle of May. For propagating purposes a hotbed or two should be formed, either entirely of leaves or partly of leaves and partly of litter, in which to propagate plants by seeds, cuttings, leaves, roots, eyes, &c., and to start into growth dormant bulbs and plants that were rested during the winter. Seeds of most kinds of flower garden plants should be sown in them as soon as the heat subsides a little, and pricked off as soon as they have become sufficiently far advanced for that purpose. *Caladiums*, *Achimenes*, some species of *Gesneras*, *Gloriosas*, *Curcumas*, &c., may all be started now into growth, either in the pots they permanently occupy or in smaller ones, afterwards to be transferred to larger ones. Fern spores may also be sown in these hotbeds, but owing to the long time they generally take to vegetate, a heated pit is the most suitable place for them.

**Hardy Fruit Garden.**—All fruit trees should be pruned before this time, and their trunks and main branches cleared of Moss and Lichens. Young trees may yet be planted, and any old ones intended for transplanting next autumn should have their roots cut now, by which means they do not suffer nearly so much in removal as they otherwise would do. Prune back to fifteen inches above ground stocks on which grafts are to be put. Match the roots of lately planted trees, and affix strong stakes to all that require support; see also that espaliers are sufficiently staked and tied. Have all trees on walls properly pruned and nailed, as the flower buds are more than usually forward this spring. A good syringing with sulphur and water well mixed will be found very beneficial to wall trees. Make new Strawberry plantations and fill up empty spaces in old ones; remove all runners, dig between the rows, and apply a good mulching of litter between the rows on the surface of the soil. Collect all prunings and other rubbish and burn them, saving the ashes and likewise the charcoal resulting from the operation for manurial purposes. The prunings may be advantageously used in burning clay for applying to stiff soil, in order to lighten it and to render it porous.

**Kitchen Garden.**—Where advantage has been taken of the open weather which we have had for trenching and ridging every available piece of ground, satisfactory results may now be realised. Quarters not so treated are often so cold and damp that seeds sown in them perish, whereas well-trenched ground in almost all cases will be found in good condition. Draw earth to rows of Peas, and at the same time stake them. Sow a succession of marrow kinds, with one or two rows of Round Spinach between the rows. A plantation of early Potatoes should now be made in some warm quarter and in rather light soil; those in pits should be examined, rotten or diseased ones removed, and all sprouts rubbed off. Of Jerusalem Artichokes a plantation may be made in any odd corner, and all tubers of last year's crop yet in the ground should be lifted and housed. Any other roots of Parsnips, Beet, Carrots, and Potatoes left in the ground must now be lifted; for, although their flavour is maintained if kept in the ground during winter, unless they are lifted now they begin to grow, and their quality is consequently greatly reduced, for they become stringy. Some of the finest roots of Parsnips, Beet, and Carrots may be transplanted to a favourable position for seed. Sow some Early Turnips in a light warm soil. Of Cabbages sow some of the early sorts for summer produce, also some Red Cabbage, some Walcheren Broccoli, and Savoy seeds; Savoys sown early grow much larger than late sown ones. A sowing of Onions should be made as soon as the ground is ready. Onions are sometimes grown year after year on the same piece of ground, but that is a practice which cannot be recommended, better results being obtained from rotation with other crops on deeply trenched and well manured ground. Make a good sowing of Marshall's Dwarf Beans. Sow some Leeks, Chervil, Fennel, Dill, Parsley, &c. Increase pot herbs by division or by means of seeds. Make new plantations of Rhubarb, planting the crowns in lines 3 feet apart and 3 feet asunder in the row. Of Horseradish make fresh plantations in deeply trenched and well manured ground, the manure being kept in the bottom of the trenches, otherwise the roots fork. Crowns or pieces of the roots should be used for the purpose, and be dibbled in 18 inches deep.

## MARKET GARDENS.

Where ground was trenched up into ridges before the late frost, it will now be in excellent condition for receiving plants or seeds, crumbling down freely upon the slightest touch and being moderately dry. The ridges of a part of the trenched ground ought to be levelled down with wooden-toothed rakes, and lines for Lettuces marked on the surface about 20 inches apart. This crop may be planted at once, choosing the most forward of the plants on those

grown amongst Carrots for the purpose, and dibbling them in about 9 inches asunder in the row. Between these Lettuces lines may be drawn and Parsnips sown; the Lettuce crop will be removed before injury is done by it to the Parsnips. About the first of the month the main crop of Onions should be sown on ground that has been lying in trenched ridges for some time. Sow some beds of white Dutch Turnips and protect them, if practicable, with litter; they may, however, do quite well without it, although its assistance not only preserves them from birds but also from cold. Radishes that have not been covered are almost completely ruined; indeed, some that were sown at the base of a wall on a warm border six weeks ago have hardly vegetated, on account of the cold; what did come, except such as are quite close to the wall, are too stunted to be of any use—all through the effects of cold. By covering newly-sown Radish, Turnip, and Cabbage or Cauliflower seeds with litter until they germinate, and afterwards during cold weather and at night, not only is the security of the crop effected, but it is brought forward almost as rapidly as if covered with glass. Where a portion of the trenched ground can be spared, some of the best of the Cauliflower plants should be transplanted and protected with cloches or round vegetable baskets. For a few days after transplanting some earth should be drawn around the edges of the cloches or baskets until the plants begin to take root. As Cauliflower frames generally occupy a sheltered position, their site forms a good situation for Tomatoes, early French Beans, or for Cucumber frames. Some Cucumber seeds should be sown at once, if not previously done, in seed pans, and placed in a brisk hotbed. As soon as they vegetate, they should be pricked off two in a 6-inch pot, and replunged in the hotbed; after a time they may either be potted singly or transplanted permanently without being repotted. Frames for the reception of young plants must be got in readiness; last year's ones cleaned out will do, or new ones for the purpose may be made; 3 feet deep, 5 feet wide, and of any desired length are the common dimensions, consequently pits must be made accordingly, and filled with fermenting manure, which should be trodden quite firmly, so as to retain the heat longer than it otherwise would do. Over the manure some good soil should be placed, the frames set on and filled to within 10 inches or so of the glass with soil, and the plants planted. In private gardens the Cucumber and Melon frames are mostly on dung-beds above the surface of the earth, but those in market gardens are all on sunken beds, so that the frames are not much higher above-ground than an ordinary Cauliflower or Lettuce frame. This is found to be the most convenient arrangement.

#### NURSERIES.

**Indoor Department.**—The general repotting of all greenhouse and stove plants should now be pushed forward. Some plants are already in large enough pots for marketable purposes, therefore it is not advisable to repot them; merely clean the surface of the soil, removing with a wooden peg such of it as is free from roots, and surface dress with fresh soil. Small climbers, as well as many other plants, always sell best in 48 or 60-sized pots, and when they are reshifted or planted out permanently, the roots should be loosened and well spread out. Young Azaleas and Camellias not set with flowers should be repotted, placed in a close pit, the heat and moisture of which should be increased as the days advance. They should be syringed daily, shaded from strong sunshine, and have their growths pinched when they become 4 or 5 inches long. Cut back such plants of *Burchellia capensis*, *Aloysia citriodora*, *Brugmansias*, *Plumbago capensis*, *Cassias*, *Lagerstrœmia indica*, *Fuchsias*, *Clematises*, and other plants as are now beginning to grow. Roots of *Begonias*, *Caladiums*, *Achimenes*, *Curcumas*, *Gloriosas*, *Alocasias*, *Aristolochias*, *Blandfordias*, *Erythrinæ*, and many other plants that have been at rest during the winter, should now be started into growth. Bulbs of all sorts, such as *Lilies*, *Crinums*, *Nerines*, *Hippeastrums*, *Vallotas*, &c., should now be in a growing condition, but it is sometimes desirable to retain a few without starting for some weeks yet for late bloom. Palm seeds of all sorts ought now to be sown in a warm moist pit or frame. Various methods of sowing these are practised; some sow them in pots or boxes, and pot off the seedlings singly some months after germination, or perhaps a year or more may elapse between sowing and potting; a good plan, however, is to take an ordinary flat Strawberry punnet or seed pan, and to half fill it with cocoa-nut fibre, then to lay the seeds in it thickly, and to cover them over with another thin coating of the same material, and then to plunge the baskets or punnets in a moderately brisk bottom heat. A number of small pots should then be got ready and filled with sandy peat, or with the admixture of a little loam; after the seeds have burst and the plumules have emerged about an inch, prick off a seed into each little pot, so that the seed itself may lie on the surface of the soil. The pots should then be plunged in the hotbed and covered over with a frame or handlight.

#### NOTES OF THE WEEK.

— WE learn that General G. A. Von Jacobi is continuing his valuable work on the genus *Agave*. A second supplement to his monograph of these interesting plants, containing descriptions of many new species, has just appeared in the "Memoirs of the National Society of Silesia."

— MR. CHARLES S. SARGENT, of Brookline, has been appointed Professor of Horticulture in the "Farm School" of Harvard University. An important feature of this department is a garden in which pupils can obtain not only practical instruction, but actual experience of the business of gardening.

— A CORRESPONDENT of the *Cologne Gazette* writes that having noticed the *Phylloxera vastatrix* on a Burgundy Vine which he had received and planted last year, he washed it with water in which anise seed had been boiled, the water being thoroughly impregnated with the smell and taste of anise, and the Vine has completely recovered.

— PROFESSOR BERNARDIN, of Ghent, who has for some time devoted himself to investigations in economic botany, describes, in his last publication 100 plants which produce india-rubber and gutta-percha. He states that india-rubber is obtained chiefly from the *Ficuses* and plants of the *Euphorbiaceæ* family, while gutta-percha is the product of plants which belong to the family *Sapotaceæ*.

— IN a letter from Professor Owen, who is now the guest of the Khedive in Egypt, we learn so much of the beauty of the gardens of that country in winter, that we almost wish we could exchange places with the swallows, who are enabled so easily to escape from disagreeable regions in winter to enjoy a better climate. The Professor describes the garden which surrounds his residence as being full of *Mignonette*, *Zinnias*, *Marigolds*, *Beans*, *Roses*, bedding plants, and many other of our summer favorites, all in full sweet bloom.

— A PRIZE of ten guineas is to be awarded triennially to any student who has attended the botanical class at the Royal Botanic Garden, Edinburgh, during at least one of the three years preceding the award, and has gained honours in the class examinations. The prize is to be awarded for practical research. The subject for competition is to be intimated by the council at the commencement of each triennial period, along with a notice of the manner in which the prize is to be awarded.

— IT is not generally known that the Orange has been for a long time extensively cultivated in Japan. Such, however, is the fact, which, strange to say, has never been mentioned by writers who have described that country—not even by Siebold. This ignorance, no doubt, was due to the restrictions which the Japanese formerly placed upon foreign visitors, and which prevented them from obtaining that accurate knowledge of the country with which (thanks to the more sensible and liberal policy recently adopted by the Japanese Government) the rest of the world is likely soon to become familiar.

— THE bright sky-blue *Anemone apennina* has been in fine flower in the open grounds at the Hale Farm Nursery, Tottenham, for these last ten days, also the spring *Snowflake*, the little early *Squill* (*Scilla bifolia*), *Scopolia orientalis*, and the charming little *Rhododendron præcox*. In frames at the same establishment *Primula verticillata* and *erosa*, *Saxifraga ciliata*, *Iberis sempervirens*, *Schizostylis coccinea*, various *Cyclamens*, *American Cowslips*, *Iris reticulata*, *tuberosa*, *pumila*, *persica*, four varieties of *Narcissus*, and *Primula cortusoides amœna* are all in full flower.

— DURING the violent storm which occurred on the 12th of last December, a remarkable tree was blown down and destroyed. This was a common Horse Chestnut, forming one of a plantation of these trees which was made in the park of the Château de Berey in the year 1600. It was, consequently, 272 years old, at the least, when it perished, yet, during the previous summer, it had exhibited a vigorous growth, and would probably have lived many years longer, had its roots possessed a more tenacious hold of the soil, the trunk (which was nearly 6 feet in diameter) being comparatively sound. Most of the ground which formed this ancient park is now built over, and the old tree, in its fall, crushed the storehouse of a wine merchant, causing him a loss of more than thirty hogsheds of wine.

— THE Horticultural Society of Seine-et-Oise will hold an exhibition at Versailles during the last two days of next May and the 1st of June, open to all gardeners, amateur and professional. No manufactures will be exhibited except such as have a direct relation to horticulture. Exhibitors may compete in any of the 109 classes which are comprised under the following general heads:—New plants introduced, plants raised from seed, good culture, hot-house, temperate house, open-air, plants in peat soil, fruit trees, vegetables, fruit, objects of art and manufactures relating to horticulture. All matters to be exhibited must be located in their proper places in the pavilion of

the exhibition, at the exhibitors' expense, not later than six o'clock p.m. on Wednesday, May 28. The jury will assemble on the 29th of May, at ten p.m., in the grounds of the exhibition.

— THE Castor-oil Plant is now cultivated in California, and an average crop of 400 lbs. of oil to the acre is obtained.

— WE have just received the fifteenth edition of Mr. Rivers's "Orchard House."

— WE learn that a weeping form of that fine American tree, the Hemlock Spruce, has recently originated in New York. It droops, it is said, nearly as much as the Kilmarnock Weeping Willow.

— WE understand that the business of hot-water engineer hitherto carried on by Mr. T. S. Truss, Friar Street, S.E., has been converted into a company, called "The Patent Pipe and Boiler Foundry Company (Limited)."

— It has been ascertained that the acreage under Flax in Ireland last year was 20 per cent. less than in 1872; but there was an increased yield of 38 per cent., and, with moderately good weather, the crop would have compared favourably with the highest ever obtained in that country.

— M. LEON SISLEY, writing from Japan on the 17th of last November, states that the fruit crop of the *Diospyros Kaki* or Date Plum was at that date nearly all gathered in. This intelligence is not a little surprising, as, even in the warm parts of France, the *Diospyros* does not mature its fruit before the end of December.

— AN American has made an experiment with the view of ascertaining how far soil is protected from cold by snow. For four successive winter days, there being 4 inches of snow on a level, he found the average temperature immediately above the snow 14° below zero; immediately beneath, 10° above zero; and under a drift 2 feet deep, 27° above zero.

— M. B. VERLOF, the distinguished director of the herbaceous department in the *Jardin des Plantes* at Paris, has just published an interesting and instructive book on Alpine plants, a work for which his long experience as a collector of these plants has specially qualified him. It forms a handsome octavo volume of 320 pages, illustrated with 150 coloured plates, and 78 wood-cuts. We shall give a more detailed account of it in a future number.

— WE learn that a series of grand national Flower and Fruit Shows are to be held in the grounds connected with the Dublin Industrial Exhibition Palace, during the months of June, July, September, and November next. Schedules of prizes have been issued, and the dates fixed for holding the shows are June 11th and 12th; July 2nd and 3rd (the Grand National Rose Show); September 10th, 11th, and 12th; and November 19th, 20th, and 21st.

— It is deplorable to see (says a correspondent of the *Daily News*) into what a state the Vatican Gardens have fallen. One might almost imagine oneself in a forest. Even those parts which are mostly frequented by the Pope are completely neglected. There may, however, be a little artifice in all this. The staff of gardeners was very large previous to the 20th of September, 1870; but since that date many have been dismissed, on the ground that his Holiness could not afford to retain their services. The same thing was done by the churches and all the other dependencies of the Vatican.

— M. J. B. WEBER, the Director of the Botanic Garden at Dijon, considers the Potato-disease to be quite analogous to the *Oidium* of the Vine, and believes that it may be successfully combated in the same manner, *i. e.*, by sulphur dusting. He has arrived at this conclusion from the fact that some rows of Potatoes which were planted close to a Vine trellis, and had received a portion of the sulphur with which the Vines were dusted, exhibited no signs of the disease, while the remainder of the crop, which was out of range of the sulphur, suffered severely from it, nearly one-fourth being rotten in a month after they were gathered. The leaves on the plants on which the sulphur had fallen continued green and unspotted up to the time when the crop was taken up, and in three rows M. Weber did not discover a single diseased tuber.

**The "Kibble" Conservatory.**—The erection of this structure in the grounds of the Botanic Gardens, Glasgow, is progressing apace, and the present idea is that it will be opened to the public about the middle of the month of May next. That it will form an addition of mark to the public exhibitions of Glasgow is an indisputable fact. Opportunity has been taken to enlarge it in several important directions, and generally to adapt it to its new situation and new uses. From the front door, which faces the west, to the extreme end of the structure is a distance of full 240 feet. The first door on the right, after entering by the front, leads into a room to be devoted to the display of interesting models and relics; a corresponding room on the left, of the same dimensions—50 by 25 feet—being used as the "Moss house," where, when completed, the visitor will be able to realise, so far, the poet's idea of "cool grot and mossy cell," with all the

advantages that art can add to nature. Passing onwards, and flanking a basin of water 24 feet in diameter, are, to right and left, two spacious refreshment rooms, leaving which we enter under the great glass dome, 150 feet in diameter and 50 feet in height. This may be called the grand reception saloon of the place, and will form a most eligible arena for promenade concerts. Already it is surrounded by casts of some of the most admirable works of sculpture that ancient and modern art, the former especially, has produced; and many valuable plants also, tree Ferns in particular, transported from Couliport, are now disposed around the circle.

## LAW NOTES.

### THE QUEEN v. COWLEY AND HUMPHREY.

THIS case raised another of those subtle questions which are constantly being raised on the law of stealing or larceny. The prisoners at the last winter assizes for the county of Sussex were indicted for stealing Onions. The prosecutor, having a cart loaded with Onions, met the prisoners, who agreed to buy all the Onions at a certain price, £3 16s., ready money, the prisoners saying "You shall have your money directly the Onions are unloaded." The Onions were accordingly unloaded by the prosecutor and the prisoners together at a place indicated by the prisoners. The prosecutor then asked for his money. The prisoners thereupon asked for a bill, and the prosecutor made out a bill accordingly. One of the prisoners said they must have a receipt from the prosecutor, and in the presence of the other made a cross upon the bill, put a penny postage stamp upon it, and then said they had a receipt and refused to restore the Onions or pay the price. The next morning the prisoners offered the Onions for sale. The jury convicted both prisoners and said they found that they never intended to pay for the Onions, and that the fraud was meditated by both the prisoners from the beginning. The prisoners' counsel insisting that under the circumstances there was no larceny, the learned Judge (Mr. Justice Byles) reserved the point. On the case being again stated the prisoners' counsel urged that it was a case of credit, on which

The Lord Chief Baron said no doubt if credit was given it could be no stealing; but the question was whether credit was given. There was no agreement for credit, and, on the contrary, there was an express agreement for ready money. In every cash sale one act must be done first—the laying down of the price, or the laying down of the article; but there is no real sale and delivery until the money is paid. The felony was completed when the prisoners got the Onions, for they got them by a trick, and meant to steal them. The court therefore unanimously affirmed the conviction.

### BROAD v. HUXLEY.

Vice-Chancellor Malins has delivered judgment in this case. The plaintiff, Mr. Broad, a retired tradesman, occupies a small leasehold house in St. John's Wood. The defendant, Professor Huxley, some time since, bought a house in Willow-gardens, from which there was a slight inclination towards the plaintiff's house. Last autumn Professor Huxley, desiring to make a lawn in front of his garden, proposed to raise the ground a little and drain it towards the plaintiff's house. The plaintiff complained that the raising of the ground caused his garden wall to bulge, that the trees which Professor Huxley had planted darkened the plaintiff's house, and principally that, by the system of drainage adopted by Professor Huxley, the basement of plaintiff's house had become uninhabitable. The Vice-Chancellor said he was satisfied by the evidence that the plaintiff had not made out a case for the interference of the court, and his bill must be dismissed with costs. It was a great pity that he had rushed into litigation. The value of the plaintiff's house was £700, and this litigation would cost him probably £500.

## COVENT GARDEN MARKET.

FEBRUARY 21ST.

Flowers, which are well supplied considering the season, have not altered in kind since our last report. Hothouse produce is confined to Grapes, Pines, and a few Strawberries, the prices of which are nominal. Some capital St. Michael's Pines are again offered, and realise rather higher prices than those quoted by us last week.

### PRICES OF FRUIT.

	s.	d.	s.	d.
Apples ... half sieve	3	0	5	6
Cobs ... .. lb.	2	0	2	6
Grapes hothouse ... lb.	6	0	12	0
Lemons ... .. 100	4	0	8	0
Melons, Spanish each	2	0	3	0
Oranges ... .. 100	4	0	8	0
Pears ... .. per doz.	8	0	12	0
Pine apples ... .. lb.	6	0	10	0
Walnuts ... .. per 100	2	0	3	0

### PRICES OF VEGETABLES.

## THE GARDEN.

"This is an art  
Which does mend nature: change it rather: but  
THE ART ITSELF IS NATURE."—*Shakespeare.*

### THE SWEET-SCENTED POND WEED.

(*APONOGETON DISTACHYON.*)

This plant has been growing in the pond of the Royal Botanic Garden, at Edinburgh, for the last 40 years, and now forms many large patches in various parts of it, the largest being 48 feet in circumference. The situation where the pond stands, was originally a marsh; when it was made, the bottom was causewayed with stones, placed half an inch apart, in order to allow the numerous springs, peculiar to that portion of land, freedom to rise between them. The pond varies from 2 to 5 feet in depth, and the bottom is thickly coated with mud, arising from the tree leaves which are annually blown into it. In this decomposed vegetable matter the *Aponogeton* thrives well, and seeds, which are abundantly produced during the autumn months, germinate freely in the muddy bottom. In consequence of the number of springs which exist, many portions of the pond are never coated with ice, even during the most severe winters. The overflow is very large, and is never found to vary at any time throughout the year, not even during very dry summers. To these circumstances I attribute the healthy condition of this beautiful pond weed, which is indigenous to the Cape of Good Hope. The *Aponogeton* flowers abundantly every year, not only during the spring, summer, and autumn, but often during the winter, particularly if the weather is at all mild. Plants of it have been sent from this establishment to many ponds throughout Great Britain, but in few has it been successful, evidently owing to the want of constant springs bubbling up amongst their roots, which causes a continual change of water. Plants of it have, however, succeeded in several mill ponds where the water is kept warm by the condensed steam constantly thrown into them.

JAMES McNAB, *Royal Botanic Gardens, Edinburgh.*

### BRITISH PLANTS FOR THE GARDEN.

SUGGESTING, the other day, to a friend who is laying out and planting a sort of semi-wilderness appendix to his garden and pleasure-ground, that he should introduce various plants from the woods in his neighbourhood, as well as aquatics and hedgerow-flowers, a bystander remarked that in England there grew wild "nothing but weeds," intending to imply thereby that nothing could be found suitable in our indigenous Flora for the ornamentation of ground intended for enjoy-

ment. A moment's reflection showed plainly that not only are there plenty of beautiful and appropriate plants only waiting the transfer, but that a very considerable number of our existing garden favourites are genuine ancient Britons. Everyone has heard of the famous scene in Molière's comedy of "Le Bourgeois Gentilhomme," where M. Jourdain is quite startled to find that he has been talking prose all his life without knowing it. Many a gardener who looks complacently on his flower-borders as constituted, he fancies, of the "rich and rare" from foreign countries, would be as much astonished, perhaps, were he to enquire carefully as to the original birth-place of the particular species, for it would turn out that many a score of the sweetest and prettiest

things that are cherished and tended so carefully, and that never go out of fashion, were brought, in the first instance, out of the fields and groves of Old England itself. That many of these garden inmates are no longer to be met with during our walks in the country is quite true; that others were always very local and scarce is probably true likewise. Their disappearance from the primitive spots is a result, in no slight measure, of the very fact of the institution and establishment of gardens; since, in the early days of horticulture, when the lovers of flowers and gardens had nothing at command except the native produce of the soil; when exotics were nearly unknown, and such common things as the *Fuchsia* and *Dahlia* had two or three centuries yet before them to "blush unseen" in their remote abodes;—there was no alternative but to select the most enjoyable things that offered, and the roots of these would of course be conveyed promptly from the wild habitat to the consecrated little spots which were the gardens of our forefathers, at last almost to the abolition of the original home. See, even at the present day, how hard it is for many a Fern to hold its own in the wilderness! If suitable for a rockery, or wanted to complete a collection, or, hard and sorry fate, thought saleable in the market-place—which often means condemned to be dried to death in the sun, and then be thrown into the dust-heap—not a frond is left remain, and the locality becomes to botanists a thing of the past. How many of the most curious and alluring of British plants have in this way (aided by the

The Sweet-scented Pond Weed.

obliterating results of drainage, &c.) now become extinct, or nearly so, in places where once abundant! Witness the wild English Lady's Slipper, *Cypripedium calceolus*, and the yellow Saxifrage, *Saxifraga hirculus*. Had the Primrose, the Cowslip, the Lily of the Valley, the Sweet Violet, the Wallflower, been less profuse, and less gifted with that spirited tenacity of their ancestral homes which forbids effacement, how certainly would these too have become botanical rarities, and a display of their blossoms be a spectacle only in the garden. Happily, the great majority of our wild-flowers, like the wild-flowers of all other countries, have got so good a grip of the paternal estate, that it is not likely they will ever become dispossessed

wholly and absolutely. There is always a probability, to say the least, of seeds lingering in the ground, or fragments of rootstocks biding their time, and which, except where the surface has been rendered wholly unfit for the maintenance of plant-life, will keep the old tradition going, and float everything forwards and onwards.

With these names just cited, before us, Lady's-Slipper, Cowslip, Primrose, &c., it behoves us to be cautious, accordingly, in the use even of the term "weeds." Every plant is a weed somewhere, if being a weed means growing wild; and the botanist will insist, perhaps, that intrinsically there is no such thing as a weed. He will, at all events, demand the recognition of the right of every plant to exist in the place for which nature designed it, and for which its peculiarities and physiognomy well adapt it. May not the crimson Musk Thistle upon the hillside hang out those glorious heads of honied filagree which the bees quit so reluctantly? And may not the Ajuga lift up its lovely pagodas of freckled blue among the young grass? No one will say nay; and yet these are only "weeds." It comes then to this, that no plant is a "weed" naturally, and inevitably, and universally. Through excessive multiplication, in localities where not wanted, a plant converts itself into a weed, technically so-called, and then must be exterminated or subjugated by force; but as long as it abides in its own proper sphere, it is no more a weed than song-birds are vermin, though did they multiply after the fashion of flies, or conduct themselves after the manner of rats, the sweetest choristers that may be would fall under the same law, and have to submit to be treated like criminals. A "weed," to put it briefly, is a flower growing where not wanted, or where it hinders the profitable use of the spot it occupies. Hence, in the Orchid house, that exquisite little Wood-sorrel from the Mauritius, with triple leaf and golden corolla, becomes a weed, as does likewise its frequent companion, that elegant Acanthaceous plant the *Gymnostachyum Cumingianum*; the spikes of lilac flowers which this latter produces asking for it, in truth, a better fate than that of Groundsel. Lilies of the Valley would become "weeds" if they interfered with the Mint bed after notice to quit.

Tried accordingly by this rule, the true and just one, England possesses no larger proportion of weeds than do other countries, and even in the arbitrary and conventional sense of the word, no small proportion of the exotics imported as flowering plants are every bit as "weedy" as the worst that, upon that rather vague charge, might be pointed out among our indigenous plants. The pleasant fact, however, and that which we set out to illustrate, is that our gardens owe much of their finest and most perennially delightful interest to the presence of British plants—plants selected in bygone days from amid the miscellaneous fantasy of the meadows and woodlands, the cliff, the mountain slope, and the seashore, and this because of their excellent qualities. Shameful would it be were they ever to be dismissed from their places, but happily there is little danger, for no one who really loves flowers could ever find it in his heart to refuse them at least a corner, while many have become so thoroughly established that they would now be missed almost as much as were they *Geraniums*. Such, for example, are the Pansy, the Forget-me-not, and the white Water Lily in the lake. Think too what a glorious phalanx of shrubs and trees hold their place in the list of natives! The Oak, the Beech, the Birch, the Holly, the Fir, the Yew, the Mountain Ash, the Guelder Rose; the Hawthorn again, the Tamarisk, Ivy, and Arbutus. Are these to count as nothing? So far from it, let the garden, the park, and pleasure-ground be carefully and thoroughly stripped of their country cousins, and though there would be plenty left to wonder at and admire, it would be much the same as if Shakespeare were expelled our libraries and the language of cultivated lips, or as if the Plantagenet Cathedrals were pulled down to make room for Goods Stations.

#### PYRAMIDAL FLOWER BEDS.

ONE or two beds of this kind are telling objects in any garden, however small—not only in those of the severely formal style, but also in places where nature has been more allowed to take part in the arrangement. When well done they have the

appearance of large cone-shaped plants, some 6 feet in diameter and as much in height. Both leaves and flowers are presented to the line of sight; there is consequently not so much glare to dazzle one's eyes as when the beds are all trained to a flat surface. Such beds associate well with masses of shrubs on grass wherever it is desirable to introduce colour to brighten up sombre foliage; and this, perhaps, is the most legitimate way of using them, although I employ them with good effect to break the formality and sameness produced by beds of low-growing plants. Nearly all kinds of plants do well under this kind of treatment; *Colens Verschaffeltii* especially comes out with that peculiarly rich metallic lustre that this plant assumes under favourable conditions. I have often heard it remarked by visitors that they must take a great deal of water, but they really do not; for when the beds are built up all the interstices are filled in with moss, and this keeps the soil moist and cool. They are easily made, and, as they are altogether above the surface, there is no preparation of site required. Beds of this kind can be made of any size, but the most suitable is about 6 feet in diameter, and about the same in height. Strike a circle of the desired size on the grass; the turf may be taken up and used elsewhere. With a crowbar make holes round the circumference of the circle 1 foot apart, and about 8 inches deep. This will give eighteen spaces, and will consequently require eighteen stakes about  $1\frac{1}{2}$  inch in diameter—nine of these to be 7 feet long, and the remainder 4 feet 6 inches long. Insert the thick ends of the stakes in the holes previously made round the circle, taking a long one and a short one alternately. Build up a cone-shaped mass of clay or strong adhesive loam in the centre of the circle, about 4 feet in diameter and 4 feet 6 inches in height, and ram it together firmly to prevent settling; then draw the stakes in at the top, and secure them with thin wire to a strong wire ring 6 inches in diameter, sawing off afterwards the projecting ends of the stakes. Ram a wire also round the tops of the short stakes, so as to brace all together, and the framework is then completed. Having secured a bundle or two of straw, damped it, and drawn it out straight, commence planting the bed by laying small handfuls of straw just inside the stakes, and then a layer of soil in the bottom; and the first row of plants may be placed about 3 or 4 inches from the bottom, and so on till the top is reached; a layer of soil, and then a row of plants placed horizontally, finishing off with one strong plant in the centre at the top. The thin seam of straw keeps the soil from running out, and when all is finished cut off with the shears the few loose straws that stick out, and fill in all the little cracks with moss. As the work proceeds, make all firm, to prevent settling. Good soil should be used for this purpose; we generally use the soil that has done duty for Cucumbers and Melons the previous year. The erection of these beds is not the formidable job the uninitiated might imagine from reading my somewhat prolix statement. No. 1 pots, filled in this way with the surplus bedding plants, are very effective for standing about terraces where there are large breadths of bare gravel. I don't attempt to disguise the fact that it takes a considerable number of plants to plant one of these beds effectively; but they are generally much admired, even by those who lose no opportunity of railing against the prevailing fashion of grouping together masses of bright colours unrelieved by foliage.

E. HOBDAV.

#### WINTER ASPECTS OF VEGETATION IN MADEIRA.

THE spring flowers of Madeira are succeeded by those of summer, those of autumn, and those of winter without interruption; and among the latter the Rose reigns still supreme. The Queen of scented flowers is there what our florists technically term in regard to a special division of the varieties, a perpetual—a true perpetual—for it not only flowers late into the autumn, like the "Perpetuals" of our English gardens, but all through the winter division of the year. A writer on board Her Majesty's Ship Challenger, now on an interesting voyage of scientific discovery, sends home a glowing account of the gardens, and of the general aspect of the vegetation of the island of Madeira during the present month of February; and though filled, as he must have been, with thoughts relating to scientific matters, he could not resist—when the

vessel anchored off Funchal, the attractions of the verdure and flowers of Madeira, as they revealed themselves to him—filling his journal of that day's impressions with vivid descriptions of the beauties of terrestrial vegetation that suddenly burst upon his sight in that lovely island, as he saw them on the 3rd of February last. Delightful and striking, says the writer, were those first impressions after coming from the monotonous sea, of the luxuriant gardens of Madeira, gay with flowering plants and high cultivation as far as the eye could reach up the mountain sides, almost to their very summits. "Nature here exhibits herself," we are told, with such varied charms that imagination can scarcely conceive a lovelier scene. A ramble on shore through some of the gardens in which the plants, though not exactly in midsummer, were in a high state of luxuriant development, proved that it was not the haze of distance that "lent enchantment to the view," but that a closer acquaintance developed new beauties, which, to be fully appreciated, required a nearer inspection. There were abundance of sweet-smelling Roses, blooming Oleanders, and Agaves more than 40 feet high; and a vast profusion of the shining green foliage of Camellias; with Cypresses, Laurels, Myrtles, sweet Magnolias, and Fuchsias; together with Banana, Sugar Cane, Coffee shrubs, Mangroves, and Pomegranates; and also the fine masses of foliage of grand Chestnut trees and Planes, which appear to be evergreen in that soft climate.

But, notwithstanding all the advantages of delicious temperature, the vegetation of Madeira is subject to occasional drawbacks, in the shape of incidental plant diseases, such as that with which the Vine has been recently visited in many parts of Europe. In Madeira, indeed, that scourge of vineyards seems to have been far more severe than in less favoured climates, insomuch that after its first appearance, in 1852, its progress was so rapid and fatal that many of the most celebrated vineyards, from which the celebrated wine was obtained of the highest qualities and in the largest quantities, have been either entirely destroyed or rendered utterly valueless. The destruction has, in fact, been so complete that the Sugar Cane has been tried with considerable success as a commercial substitute for the Vine; and two large factories have been established in the outskirts of the town, in which a large number of workmen are employed in sugar making. The February weather of the present year is described as lovely: the wild flowers as well as garden flowers being everywhere in bloom. When one thinks of these attractions within a pleasant yacht-sail of English ports, how is it that we take no advantage of the near proximity of an available summer so close at hand during the depths of our frigid winter? How is it that those who are devoted to gardens, and who, when the frosty seal of cold has been set upon them, and nipping winds have rendered their charms all but inaccessible to any but very robust lovers, blindly hasten to London to seek forgetfulness, in a round of uncongenial society, of the pleasures of which they are deprived? How strange it is that, instead of seeking the sooty retreat of a stuffy house in May Fair, they do not purchase a bright sunny villa in Madeira, and there pass the months of the year that are so dreary in England! By this temporary change of residence garden lovers would secure a continuous interest in their horticultural pursuits without the monotony of a perennial summer in England, if such a thing were possible. The vegetation of Madeira would contrast pleasantly with that of Great Britain by means of the semi-tropical character of many plants and trees which grow robustly there, while they can only be cultivated under glass with us. With the advantage of the great advances recently made in English horticulture, a much greater variety of plants might be established in Madeira than are at present in cultivation there. Indeed, it is probable that all the noble plants so exquisitely figured in the "Flora Græca" would thrive luxuriantly in that climate—and what glorious gardens they would make!—while many others, also requiring a somewhat higher temperature than that of Greece, would superadd the charm of a semi-tropical vegetation without the cultivator having to endure the serious drawback of the oppressive heat of their native climate. Madeira possesses, in fact, one of those happy temperatures in which the plants of both hot and cold climates thrive almost equally well.

Still a little nearer home are the Azores—an island group

nearly as attractive in climate and aspect as Madeira, the island of St. Michael presenting landscapes of exquisite beauty, though its winters can scarcely be said to be as equable as those of Madeira. Farther south, but still within a few days' steam or sail of England, lie the Canary Islands, on the gentle slopes of which most charming retreats might be built, and surrounded by luxuriant plantations, beautiful throughout the winter, to which we might retire in the season of our British snows and frosts, and, leaving the robin and the thrush, our only feathered songsters in winter, enjoy the cheerful sight of those pretty yellow finches which have taken the name of their island homes by which they are so well known in England, but only as cage-birds, on account of the severity of our winters. We can never, in our climate, see them flitting like flashes of yellow light among the trees and bushes of our English gardens as we might in shrubberies established round English homes in the Canaries. This change of residence for the winter months might, judging of it in the presence of a coal famine which may be of long continuance, prove a vast economy to certain classes dependent upon a fixed income, and so tend to a great increase of comfort combined with a decreased expenditure.

H.

**Climbing Tropæolums.**—Cold, bare, and formal masses of shrubs look none the worse for a little lighting-up during the summer months by means of flowers of various kinds. Few things are so acceptable for this purpose as the climbing forms of the Tropæolum, such as Lobbianum and Canariense; and if a few seeds of these be dropped into the ground just behind any dense, stiff-growing shrubs, they will soon grow and attach their young shoots to them, and then run about and flower with great freedom. Especially are the small-flowered and more refined forms of the Lobbianum section suitable for this purpose, as they are nothing without support, and yet do not grow with that degree of coarseness that characterises the commoner kinds. If the seeds are sown behind the shrubs, and as the plants grow the shoots are somewhat informally brought over towards the spectator, the effect is greatly enhanced, as the flowers are better drawn up to meet the eye. The more varied the colours used, the better. At no time need these creepers look unsightly, as at the only possible period of destruction—that is, with the early autumn frosts—they can soon be pulled off the shrubs and transferred to the rubbish heap; and if the amount of growth has not been too abundant, the shrubs will be but little the worse for their summer dressing. Once got a good plant, and it can be easily maintained from year to year by self-sown seed. Deep digging amongst shrubs should be emphatically eschewed; the surface should only be slightly pointed with a fork, or kept free from weeds with the hoe.—A. D.

**Herbaceous Plants for Smoky Districts.**—Will you kindly give me a list of herbaceous plants that will thrive in a smoky district?—AN ORIGINAL SUBSCRIBER, Leeds. [The following will answer your purpose, viz.:—

Acanthus latifolius	Dicentra eximia	Iris in vars.	Polygonum cuspidatum
longifolius	spectabilis	Lathyrus grandiflorus	Pyrethrum carneum
spinosissimus	Dictamnus rotundifolius	latifolius	Ranunculus amplexicaulis
Achillea Fraxinella	Doicætheon Meadia	Linum flavum	spicatus
Eupatorium Parmacia, fl. pl.	Echinops ruthenicus	narbonneuse	Rubbeckia hirta
Anemone angulosa	Epilobium angustifolium	perenne	speciosa
apennina	Erigeron speciosus	Lupinus polyphyllus	Saponaria ocymoides
coronaria	Erodium Manescavi	Lychnis Viscaria	Saxifraga cordifolia
fulgens	Eryngium alpinum	Lytthrum Salicaria roseum	crassifolia
japonica	amethystinum	Monarda didyma	Scutellaria alpina
sylvestris	Asclepias	Enothera	Sedum kamtschaticum
Aster Amellus	Novæ Angliæ	macrocarpa	spectabile
lavis	Novi Belgii	marginata	Silene alpestris
Novæ Angliæ	pyrenaicus	speciosa	Schafta
Reevesii	turbinellus	Orobolus vernus	Spirea palmata
versicolor	versicolor	Paonia in great variety	venusta
Baptisia	Geranium Lambertianum	Papaver bracteatum	Stachys latifolia
Callirhoe Calystegia diurna	sanguineum	lateritium orientale	Symphandra pendula
Campumula in vars	stratum	Phlox in vars.	Symphytium holocheum
Centranthus	Gypsophila paniculata	Physostegia virginiana	caucasicum
Ceropis lanceolata	Helysanum	rubricata	Tradescantia Tritonæ
Coronilla montana	Helleborus niger and its vars.	Physostegia virginiana	Trollius napellifolius
Corydalis nobilis	Hemerocallis flava	Plumbago Larpenitæ	Veronica in var.]
Delphinium in fine variety	graminea		

Elder, planted freely. As cover in woods and plantations, where little else would live, keepers used, in winter, to dibble in cuttings of Elder in all bare, naked places, being well aware of its utility as a plant for "thickening up." Lastly, the Elder makes a good plant for filling up gaps in hedges, especially where they pass under trees, and for boundary fences, where nothing else will grow. It will preserve the continuity of a hedge right up to the trunks or stems of even Beech and Horse Chestnut.—THOS. WILLIAMS, *Bath Lodge, Ormskirk.*

### THE CHAPEL-OAK OF ALLOUVILLE (PAYS DE CAUX).

THIS very remarkable tree is a specimen of the common Oak (*Quercus pedunculata*), which is believed to be about 1000 years old, and is the object of a considerable amount of veneration to the inhabitants of the district, from the circumstance that its hollow trunk has long been used as a chapel. Properly speaking, it contains two chapels, one above the other, access to the upper one being obtained by means of a spiral staircase on the

## THE INDOOR GARDEN.

### CHINESE PRIMROSES.

THE Chinese Primroses range in colour from the deepest purple to the purest white. They are improving so fast that it is impossible to specify size with exactness. The largest sort would perhaps cover a crown-piece; they are fringed, serrated, marbled, and ringed, in the most various and beautiful manner; stem after stem, heavily crowned with masses of flowers, rises boldly and to a goodly stature out of their hearts—crowns of glory supported by the beautifully-formed fern-shaped or other leaves. There are double varieties of purest white to purple, with many intermediate shades, forms, and sizes. These are more lasting and useful, though not more beautiful, than the single varieties; but they are invaluable for cutting for vase or bouquet work, which the single ones are not, the flower soon separating from its green calyx when cut. The double will stand a week, a fortnight, three weeks, or more in water, fresh and sound as

The Chapel-Oak of Allouville.

outside, as shown in the illustration. Over the entrance into the lower chapel is the following inscription: "A Notre-Dame-de-la-Paix, érigée par M. l'abbé du Detroit, en 1696."

The tree is now about 50 feet high, its top having been broken by the wind, or cut off, at some remote period, and in its place a sort of bell-tower has been erected, the top of which is about on a level with the highest branches. The lower part of the trunk is more than 11 feet in diameter. The bark, which is of a corky nature and deeply fissured, is upwards of 4 inches in thickness. Although so very old and hollow, the tree still exhibits a vigorous growth, its huge branches, which extend over an area of 2478 square yards, being annually covered with an abundant foliage, and usually bearing a large quantity of acorns. The extraordinary age of this venerable tree renders it impossible to obtain any particulars of its early history. Local tradition, however states that the district was formerly covered by a natural Oak forest, of which the Chapel-Oak of Allouville is now the sole survivor.

at first; and for bouquets, the Double White rivals in usefulness the Camellia, Stephanotis, or Gardenia. Scarcely any plants can be easier grown than these Primroses. Properly treated, their natural season of flowering may be said to be from November to April. The sun, so essential to most flowers, may be said to be unfavourable to these; as he gains strength they, unless shaded, lose beauty and freshness. But in winter and early spring they glow with a beauty, slime with a brilliancy and purity of colouring, almost unequalled. All the single varieties are best treated as annuals. After flowering, throw the plants away. Seed saving needs special skill in selection and management, and the amateur or lady gardener, unless an enthusiast, had better not attempt it. Any respectable nurseryman or florist will supply good seeds. Sow in light soil—peat or loam with a fourth part of sand—in February or March; cover the seed with an eighth of an inch of soil, and keep it rather dry until it begins to grow. As soon as the plants can be handled, prick them out, about six round

the edge of a 60 or 48-sized pot, in similar soil, with 2 inches of drainage in the bottom of the pots. Place them in a cold pit. When well rooted, shift into single pots, and again into larger as the pots become full of roots, using for the last shift a 5-inch or 6-inch pot. No single Primrose need have a larger pot than a 6-inch one. For the last shift two parts turfy loam, one of peat or leaf mould, and one of thoroughly rotted cow-dung, form a suitable compost. Add about a sixth part sharp silver sand; if this cannot be had, clean river or road sand is the next best. Beware of using pit sand with any iron in it, as the plants are impatient of this. The drainage should be carefully adjusted, as stagnant water is death to the plant, especially in November. The collar of the plant must also be kept well up in potting, and, as this is apt to leave the neck rather loose, it is good practice at the last shift to stick in three pegs of wood to form a triangular holdfast, to preserve the neck from moving about or from being wrung off by the wind or other accident.

During the summer months a cold pit, open night and day, is the best place for the plants; or from the end of June to the middle of August they might stand in a sheltered place out of doors—not, however, in wet seasons or localities, as the plant is always impatient of water overhead. It is better to draw the lights off in fine weather, and to place them on, tilted up, during rain. Either way, place them under glass in September. In October they will be coming into flower. Through November, December, January, February, and March, they will continue to lighten up room window, boudoir, and conservatory. A temperature of 45° to 50° when in flower suits them best; but they will flower well in any temperature above 40°. The frost, however, must not come nigh them; also, next to frost, their greatest enemy is damp. See, a drop has fallen into the heart of that plant; another; yet it looks all right. What a noble plant it is!—one, two, three, six flower-stems coming up stout and strong! What is that nestling over the base, like lace of the most exquisite pattern? Mildew fungus? It is all over with that plant. In removing it the whole heart comes out, with its goodly flower stems rotted through at the neck. See there is a leaf lying down on the surface of that pot in an unusual position. Lady Violet brushed it with her dress in passing? No, something with a softer tread and a gentler footstep has crushed it. A few molecules of aqueous vapour condensed upon that leaf-stalk, coalesced and fraternised, rolled down to its base by the law of gravity, and settled there; mortification followed; and not only the leaf but the main stem is now a putrid mass of decomposed vegetable matter—the plant is ruined past recovery. There are a number of dead flowers clustering around the top of that glorious truss. Off with them at once. See, where each rested there is a gangrene on the stem, and part of the truss is already decomposed.

These are not imaginary cases at all; on the contrary, they are sober facts. The lessons from them, too, are equally obvious. Not a drop of moisture in the heart, nor on the leaf-stalks, nor near the collars, if you would preserve Chinese Primroses in beauty or prolong their lives. Hence they must on no account be syringed, and in watering water the earth only; wet neither crown, nor leaf, nor leaf-stalks if it can be avoided. A pot with a turn-down spout at the end is the best. But lacking this, by a skilful use of finger, thumb, or hand the whole of the plant may be kept dry while the earth, with its full complement of roots, is well watered. The plants need a good deal of water, and the flowers become larger, the colours more bright, if half an ounce of guano to the gallon be added. The water should be of a temperature of 50° as near as may be. The plants can hardly have too much air at all times when the outside temperature is above 40°. When below that, little or no outside air must come near them. The double varieties are increased by cuttings, and in all other respects may be treated like the single ones, only they enjoy 5° or 6° more heat. There is no reason in the nature of the plant, or in any difficulty incident to its cultivation, why every sitting-room window in the kingdom, from the cottage to the palace, and all between even these wide extremes, should not be enlivened during our dull and dreary winter months by the cheerful glow and spring-like beauty of the Chinese Primrose.

D. T.

## THE CAMELLIA AS A WALL PLANT.

APART from its blossoms, the Camellia is one of our richest evergreen shrubs. When in perfect health its greenness is so dense and dark as to be felt as well as seen. The shape of the leaf and habit of the plant are likewise all that can be desired. It grows without trouble into forms of grace and beauty that in other plants are seldom reached at all, or are only attained after the most skilful and constant manipulation. The leaves are likewise of good substance, and are as lustrous as if they had been dipped in varnish. This helps to keep them free from dust, and renders them easily cleaned. Further Camellias are by no means liable to insect enemies; green fly will occasionally settle upon the tender wood as it is forming, and mealy bug and scale will occasionally crawl over them from Orange trees or other plants with which they may be associated, but they never seem at home on Camellias; and if the culture is liberal and the care painstaking, they are among the cleanest plants grown. The leaves are too tough for spiders or thrips, and nothing but the grossest neglect in their cultivation, or the setting of the plants in the face of the sun, or in a roasting, dry atmosphere, could give these small fry a foothold on Camellias. As yet I have only alluded to the beauty of the leaves; what, therefore, shall I say in reference to that of the blooms—so rich in colour and perfect in form. Take Camellias for all in all, no tribe of plants in the dead season can match them. They are also accommodating as well as beautiful. They are cheap, hardy, and easily managed. They even thrive best where many other plants refuse to grow to any useful purpose, viz., on back walls of conservatories, corridors, and passages. I have even seen some noble plants on the shady walls of semi-opaque Orangehouses. Some contend that Camellias can hardly have too much light, an opinion with which I coincide, provided they are not burned by the direct glare of the sun. But it is equally true, as has been said, that they thrive well in shady places, with little or no direct sunlight. Many of the finest Camellias are to be found on the back walls of lofty conservatories, far from the light, and the little that reaches them has to make its way through drooping pendants or wreathed masses of Passion-flower, Lapagerias, Tecomas, Tacsonias, Mandevillas, Ipomæas, and other climbers; yet thus overhung the Camellia flowers with a freedom and brilliance of colouring only equalled in brightness by that of the Pelargonium and the Rose. Camellias may be said to have solved one of the most difficult problems in horticultural architecture, viz., the clothing of the back walls of temperate houses (and the fronts for that matter) with life and beauty. In the Camellia house, full of noble trees grown by Mr. Barnes, at Bicton, not only was the house kept full but every pillar, &c., between the lights in front was clothed from base to summit with a secondary screen of Camellias, dense, glossy, and brilliant. I have also seen panelled walls admirably furnished with Camellias at different places, each panel containing a plant, and the pillars and other projections between being furnished with varieties of different colours. The contrast between the endless shades of red, pink, and white, by this mode of furnishing, was admirable. Each plant occupied its appointed place, and was made to fill it without overcrowding its neighbour.

Cut Camellias back when and where one will they soon push forth new shoots; but the best time to cut Camellias is the moment they have finished flowering—nay, even when they are in full flower; for by the time the blooms drop the wood-buds in many varieties are in full growth. They will bear cutting even when in this condition, but these broken buds represent a loss of growing force. Had the shoots been cut back before, that force would have been utilised. How far, it may be asked, should they be cut back? Well that depends upon circumstances. But all the terminal buds or flowers of Camellias may be cut with sufficient stalk for bouquets or vase decoration. The pruning must in fact be made subservient to the furnishing, that is, cut back to insure regular clothing of the wall from the base upwards; but if the space is already full, then cut back to keep it so. Of course all severe cutting must be deferred until the flowering period is over; unless, indeed, some large branches are wanted for dinner-table or drawing-room decoration. Camellias in the form of free branches are rich and charming beyond most

flowers. In single blooms, however rich, it is difficult to avoid flatness; but with branches one can do anything in the way of room decoration. And if they are preferred in rooms to being on plants, either in the conservatory or on walls, why to rooms let them cheerfully go. I would only put in one condition in the interest of their owners, viz., always let the growers cut the flowers, and for this simple reason, that in cutting we can and do kill two birds with one stone—we cut for the present and for the future. Gardeners, however, will often neither cut their best flowers themselves nor allow (the word is hardly too strong) their owners to cut them. This feeling, when allowed to run to excess, sadly mars the enjoyment of a garden, and hinders its smooth and peaceful management. All I ask is that we may be permitted to cut with our own hands our best, richest, and sweetest treasures for our employer's use, simply because we can do it with the least amount of injury to the plants, and can cut for a continuous supply of flowers.

What I have said about cutting relates only to Camellias and other choice plants. Every lady or gentleman who has a taste for cutting and arranging flowers will of course have free scope among Roses, Carnations, and all manner of flowers of that kind, where they may cut and come again without any cold looks from those who are held responsible for the perfect furnishing of other departments. Of course the cutting of flowers may easily be carried to excess. But, after all, employers must be the judges; and if they like the excess, what matters it to us? And in regard to Camellias, I had almost written the more flowers cut off them the better. Of course the more cut the fewer on the wall or on the plants; but even that may prove an improvement. I have seen noble plants of white, and red, and pink Camellias, on walls and off, made to look better by having half the flowers taken off; this enabled the leaves to come in between and soften down the dazzling blooms.

D. T. FISU.

HYBRIDISING ORCHIDS.

THERE is nothing particularly difficult in the mere mechanical operation of fertilising Orchids; for, in the generality of cases, the pollen has only to be applied to the stigma in order to induce fruitfulness. It may, however, be as well to note that both the pollen and stigma vary in structure and general conformation from those of most other plants. The pollen masses are of a waxy consistence, and may be reached by removing the little cap (anther) at the end of the column. The stigma, or stigmatic surface as it is generally called, lies immediately beneath the apex of the column, and is often of considerable size. Any small point, such as that of a quill toothpick, may be used to remove the pollen, and to place it in the stigmatic cavity. The pollen masses of some genera are furnished with a viscid or gummy disc, which readily adheres to the point used. The pollen masses, however, of some Orchids, such as Cattleyas, and especially Dendrobiums, will not readily adhere to the point used; but to obviate any little difficulty this may occasion, insert your toothpick into the stigmatic cavity, when it will become coated with the viscid matter or mucus therein contained, and to which the pollen masses will readily adhere, no matter how dry and glossy they may be. In a few hours after the flower is fertilized, it commences to wither, and an interesting change takes place with regard to the stigmatic cavity. This cavity is widely distended previous to fertilisation, but as soon as that actually takes place, the sides begin to contract, and finally close in on the cavity, in some cases even overlapping, and thus effectually preventing the possibility of the pollen being removed by insect or other agency, or becoming damaged by water or other foreign body coming in contact with it. The ovary enlarges rapidly after fertilisation; the capsules of Phalenopsis, which are rarely half an inch long before that takes place, attain a length of from 4 to 6 inches, and the thickness of the little finger, in about sixty days after that has taken place, and contain many hundreds of minute ovals. The great difficulty, however, does not lie in the mere fertilisation, but in obtaining a fair percentage of good seed; and, as before mentioned, it is requisite for the parent plant to be in the highest state of health, in order to produce seed in good condition.

After many careful experiments, I have come to the

conclusion that perfect seeds are produced much more rarely than is generally supposed; indeed, I believe Orchids produce good seed but very seldom, and to this may be attributed the many failures that cultivators have experienced in their attempts to raise hybrids. When Orchid seeds are obtained, they should be examined under a good microscope; if they are perfect, the nucleus ought to be seen beneath the translucent, membranous, reticulated testa or seed coat. If the nucleus is not developed, it is useless to expect germination to take place—we might as well expect to obtain a batch of young Ferns after having sown the empty spore-cases, which last is far from being an uncommon occurrence. Not forgetting what has already been achieved in the way of hybrids, it will be generally admitted that as cultivators we have still much to learn, in so far as the raising of Orchids from seed is concerned. That which has already been done in this direction ought to induce those who have the opportunity to undertake more extended researches—take, for example, \**Calanthe Veitchii*, one of the most beautiful Orchids at present in cultivation, or \**Cattleya exoniensis*, together with \**Cypripedium Harrisianum*, or \**Cypripedium (Selenipedium) Dominianum*. Two growers at least have succeeded in rearing seedling plants of the beautiful and rare *Cypripedium (Selenipedium) Schlimii*, viz., M. Leroy, Passy (France), and Mr. Pilcher, gardener to S. Rucker, Esq., of Wandsworth. Perhaps the most brilliant success has attended the patience and perseverance of Mr. Dominy, of the Royal Exotic Nursery, Chelsea, who has succeeded in crossing several genera, amongst which may be mentioned *Phajus* with *Calanthe*, and *Calanthe* with *Limatodes*.

I have here compiled a list of hybrid Orchids, with their parents, where known. More might be added, but this is

1. Column of an Orchid. A, anther; B, stigmatic cavity. 2. Pollinia of Vandea (Burlingtonia). 3 and 4. Pollinia of Epuloneura (Laelia and Cattleya). 5. Pollinia of Malaxidee (Dendrobium). 6. Pollinia of Ophrydece (Disa). 7. Pollen grains separated by maceration, and seen under a microscope.

sufficient to show that much has already been done; and we may fairly ask, have these results done nothing for botanical science? By hybridisation and grafting we may prove the natural affinity of plants far better than by poring over herbarium specimens—if not so quickly, with far greater certainty. Unfortunately for horticultural science, neither Mr. Dominy nor Mr. Pilcher have as yet given us the details of their successful experiments.

HYBRID ORCHIDS.

Calanthe Masuca.	Cattleya Loddigesii.	Cypripedium Pearcei (caricimim).
Calanthe Domini.	Cattleya Brabantica.	Cypripedium Dominianum.
Calanthe furcata.	Cattleya Aelandia.	Cypripedium caudatum.
Limatodes rosea.	Cattleya (Laelia) crispata.	Cypripedium barbatum.
Calanthe Veitchii.	Cattleya Sidneiiana.	*Cypripedium Harrisianum.
Calanthe vestita.	Cattleya granulosa.	Cypripedium villosum.
Cattleya granulosa.	Phajus grandifolius.	
Cattleya hybrida.	Phajus irroratus.	
Cattleya Harrisianae.	Calanthe vestita.	
Cattleya Mossiae.	Goodyera discolor.	
Cattleya exoniensis.	Ameeteochilus Domini.	
Laelia purpurata.	Ameeteochilus xanthophyllus.	
Cattleya amethystina.	Goodyera discolor.	
Cattleya irrorata.	*Goodyera Veitchii.	
Laelia elegans.	Ameeteochilus Veitchii.	
Cattleya Aelandia.	Acrides affine.	
Cattleya quinquecolor.	Acrides hybridum.	
Cattleya Forbesii.	Acrides Fieblingii.	
		Cattleya Mossiae.
		Cattleya Manglesi.
		Cattleya Loddigesii.

Talking of sowing Orchid seed, here is a recipe from the pen of the late Donald Beaton:—

"Get the seed-pod of an Orchid emptied on a piece of smooth paper, the seeds being as small as the dust in a sunbeam. Take a very clean No. 32 pot, and put a No. 60 pot upside down over the hole at the bottom, and put a piece 2 inches square of ragged turf of fibry peat over the hole of No. 60. Then take four pieces of rough, cracked charcoal, 3 inches or 4 four inches long, and half that in width or thickness, place them on their ends against the sides of the big pot at equal distances; put your finger on the bottom hole outside, and fill the pot with water, holding the pot in the left hand. Now sow the seeds on the water, and breathe against it till the whole surface is equally dusted. Then begin to let off the water from under your finger by the bottom hole very, very gradually. As the water subsides in the pot, the seeds will stick to the sides of the pot, the peat, and the charcoal, just like so much of a tide mark. When the water is all off, place the pot in a saucer of water, with an inch deep of water in it, and hold it to that point till your seedlings are safely on the wing; put two twigs across the mouth of the pot, and put a square of glass over the twigs, so as to leave a space for air all round the thickness of the twigs. Put the pot where it will not get more dry than it is now, and where the heat is at Calcutta point; and if 99 out of every 100 of the seeds will not vegetate, and that very soon, why the pollen has not given them the germ of life. I brought 1000 Orchids into this world just that way, but, truth to say, they all of them found the means of getting out of the world by a route I never could fathom."

Another is as follows:—

"I have seen ripe seed-pods hanging abundantly from *Broughtonia sanguinea*, from *Angraecum fimbriae*, and from some of the *Oncidiums* and *Epidendrums* in Jamaica; and as we know, of course, that all the species are naturally reproduced from seed, horticultural science ought to be able to solve the problem of their reproduction here. May we not look for seed packets of the epiphytall Orchids to be advertised for sale before many years as regularly as Balsam and Primula seed, if not quite so cheaply?"

Perhaps the best manner of raising seedlings is to sow the seed as soon as ripe, on the surface of pots or blocks that are covered with living Sphagnum. If the seeds are good, in all probability some few out of the thousands that each capsule contains will make their appearance. The time they take to germinate appears to be very uncertain, some requiring only two or three months, while others remain as many years before they show themselves. *Disa grandiflora* is one of the easiest to obtain from seed; a friend informs me that he has hundreds of young plants from a single pod. *Cypripedium*, also, appears to germinate readily, three or four hybrids having already been obtained.

As a matter of course it cannot for a moment be supposed that seedling Orchids will supersede imported plants, provided we can rely on the stock abroad holding out; and we know that there are some Orchids rare, even in their native habitats—*Phalenopsis intermedia* Portei, *P. Lowii*, and the beautiful *Aerides Schroederi* (*A. crispum* var. *Schroederi*) being amongst the number. Again, it cannot be denied that some considerable time must elapse ere seedlings will reach a flowering condition, but this in practice would not prove a serious drawback, since if seedlings were reared year by year there would always be some in a blooming state. In the case of seedlings, there is always an uncertainty as to what they may eventually prove to be, but should they turn out distinct, there can be no doubt but that, in a pecuniary point of view, the rearing of them would be a decided success. Doubtless, when the germination of Orchid seeds is better understood, hybridisation will give us many other new and beautiful varieties.

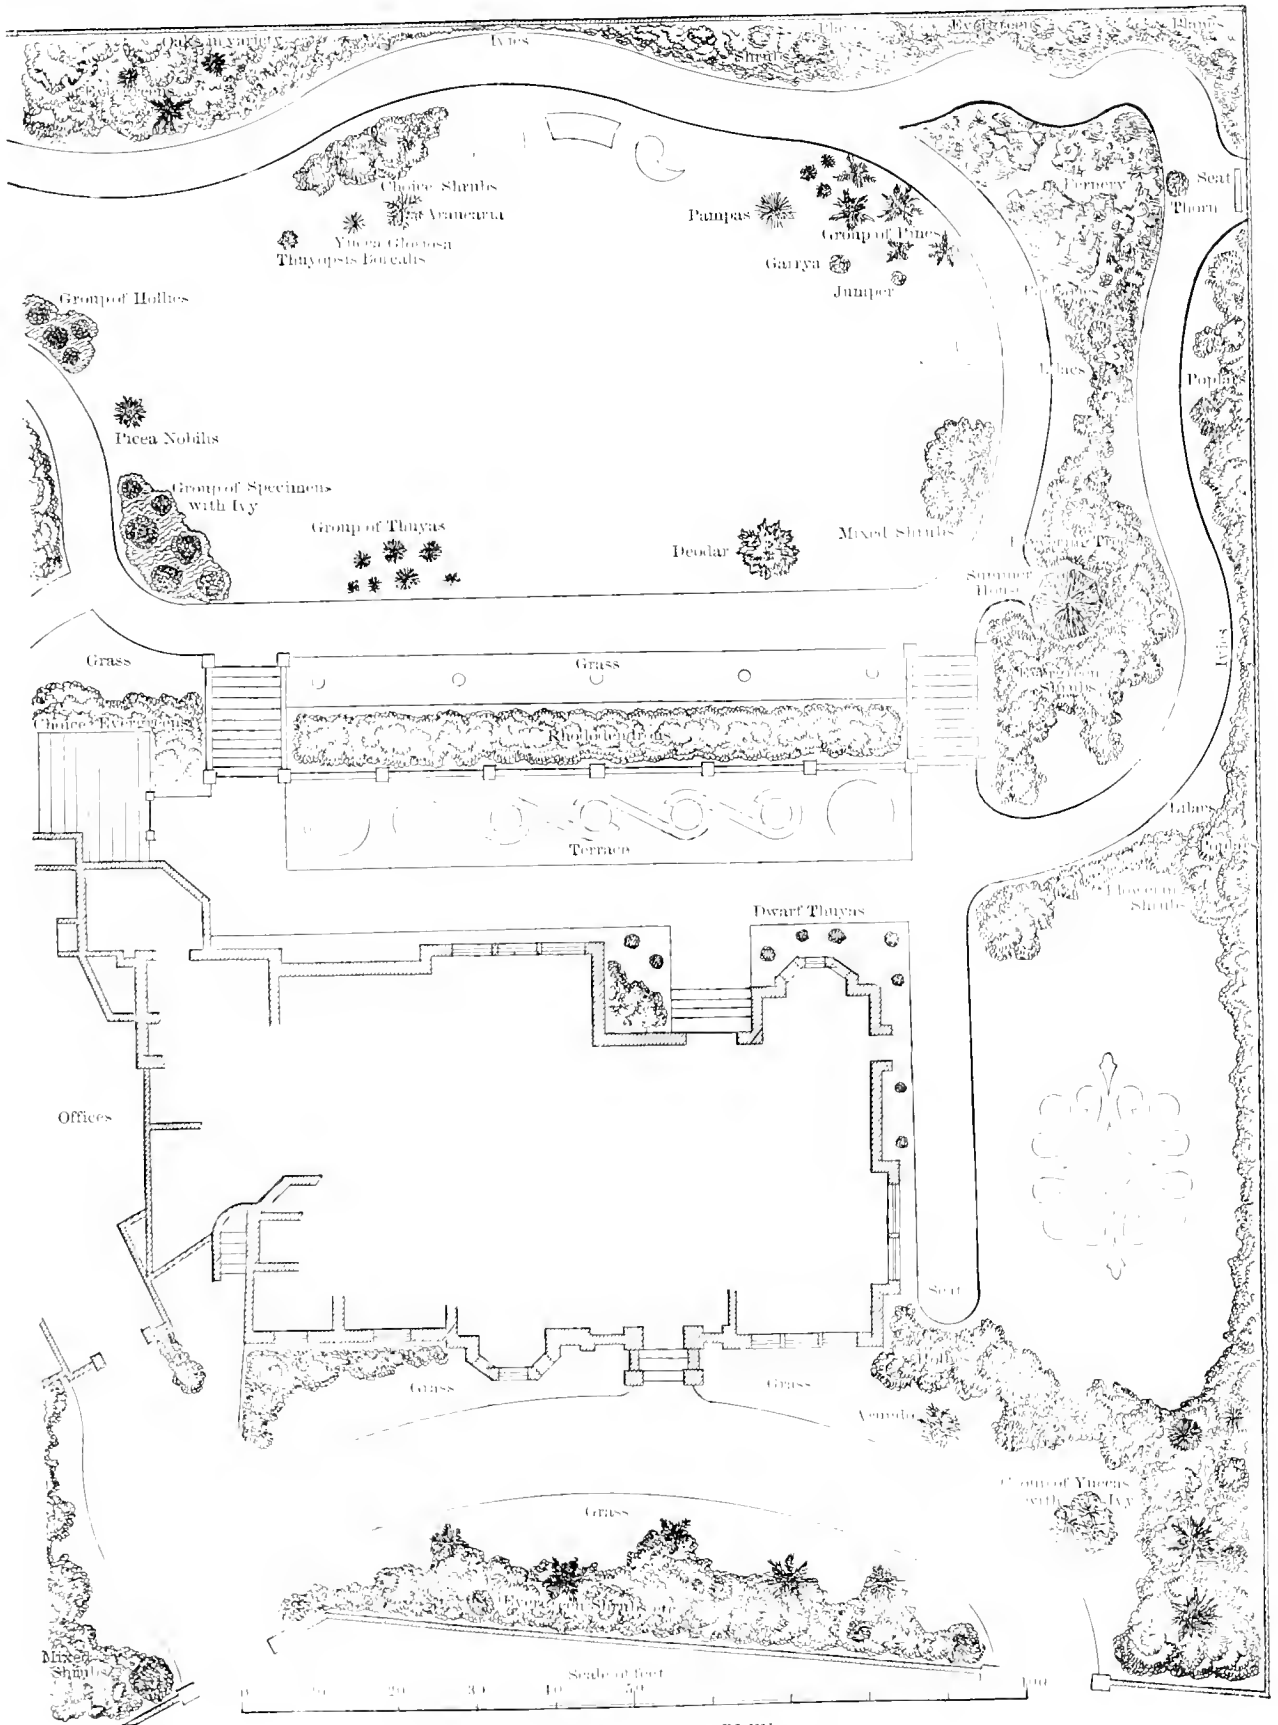

How are we to account for the many varieties of *Cattleya Mossiae*, unless crossing by insect agency has taken place in their native habitats, and these plants are seedlings? If the seed, then, germinates abroad, why is it so difficult to manage here at home? If we look at what has already been effected, we shall see that our list of hybrids does not include many

genera,—*Cattleya*, *Cypripedium*, *Goodyera*, *Phajus*, *Calanthe*, *Laelia*, *Anacochilus*, *Aerides*, and *Limatodes* being all. *Dendrobiums* have been raised from seed, in an Orchid establishment near Manchester, but whether hybrids or not I cannot say. There would appear to be a natural affinity between *Calanthe* and *Phajus*, seeing that they cross most readily, although botanically one belongs to the *Vanda* and the other to *Epidendrea*.  
F. W. B.

#### A SUBURBAN GARDEN.

The garden of which we this week publish a plan is one of a very numerous class, which is daily increasing too, and of which good models are very desirable. The plan shows the ornamental portion of the gardens at Everleigh, the residence of Dr. Andrews, and, as will be seen, is limited in size—all the greater reason why no pains should be spared in its design. If in casting an eye over the plan we begin with the strip of planting which screens the house from the road, we see a free and well broken margin, the very reverse of the common stiff, straight, or curved one. On such irregular margins it is a very good plan to further vary the edge by planting dwarf shrubs or herbaceous plants on the grass, beyond the earth-line of the plantation. This plan has within a few years past been adopted in some of the London parks. On the other side of the entrance drive also the group of *Yuccas* on a low mound, with a carpet of *Ivies* beneath them, is worthy of a word of praise. The *Ivies* do away with the necessity of mowing or otherwise interfering with the surface of the ground beneath the *Yuccas*, and both subjects are green and effective throughout the year. On the lawn is a group of specimen shrubs, with a carpet of Irish Ivy beneath them. This, or indeed any other ornamental carpet, is much better than the ordinary bare surface usual beneath shrubs. The lawn, for its size, is open and embellished with choice groups of Pines, and the lines of sight through it are so disposed that the best obtainable views are secured. The system of using the names of the plants, &c., instead of numerals in the plan, renders any further allusion to the planting, &c., unnecessary. The garden has been designed and planted by Mr. E. T. Chamberlaine, of Haverstock Hill.

**Tithe Commissioners and Newly-Cultivated Land.**—Those who have lately called attention to the "reopening of the tithe settlement" are certainly fortunate in many of the instances of this reopening which they are able to bring forward. If anything was wanted to convince the public of the intolerably vexatious results which the Act, as now judicially interpreted, will produce in the future, it would be only necessary to consider those which have already taken place. A correspondent of the *Times*, after stating that the result of an "expensive and laborious inquiry before the Assistant Tithe Commissioners, extending over eleven days," was only to bring some five acres of land under the "extraordinary charge," proceeds to give a brief description of the pieces of land thus convicted of being "newly cultivated." No. 1 consisted of half an acre lying within a hundred yards of the sea. The tenant broke up a piece of old turnpike road which used to run through it, cleared the sand off another portion of the plot, and grew in it in rotation Broccoli and Asparagus. It forthwith became a "market garden," with all its portentous consequences of contributing to bring an Assistant Tithe Commissioner down from London to make the whole parish subject to an extraordinary tithe rent-charge. No. 2, less than half an acre, was part of a very rough furze croft, and was given to a labourer rent free for some years to "bring in." He bestowed much labour on it early and late, and grew on it last year some early Potatoes and Broccoli. It is now to be declared a "market garden," with all its consequences, one of which will certainly be to prevent any other labourer from having the advantage of other portions of the same rough ground rent free. No. 3, about three-quarters of an acre, was another case in which portions of a disused road had been broken up with much labour, and Broccoli and Potatoes substituted for granite. The owner of this has rendered himself liable to an extraordinary charge in respect of the "market garden" thus formed. No. 4 was a patch of ground covered with furze and stones, which had been reclaimed at a cost of £10 an acre. It was now used as a Potato field; and a Potato field is a "market garden," according to the latest interpretation of the Act, and subject as such to the enhanced charge.

A SUBURBAN GARDEN.

## THE FRUIT GARDEN.

### BARREN OLD FRUIT TREES.

This is a subject upon which a great deal has been written, but which is capable of explanation in very few words. In the great majority of cases the pruner was carrying on a perpetual and most unprofitable war with nature by cutting in and in the whole young growth of a fruit tree, and keeping it to a very much dwarfer compass than it would naturally attain to, but never touching the root at all. The result was, that the trees grew as most plants do when cut down, *i.e.*, burst up with renewed vigour in very stout, watery shoots, which, however, are never fruit-bearing, but which would ramify into and support what ought to be fruit-bearing wood in a few years. In the case of garden-wall trees, &c., this was cut off every year; and so went on the ruinous war between man and tree. In our climate generally Pears, Plums, and other fruit trees are apt to run too much to wood rather than to a compact free-fruited state, from want of sun and heat in autumn to ripen the wood and induce fertility. But if the bottom or subsoil is good, trees left to themselves, and allowed to exist with the natural balance between the root and branches, often bear abundantly and satisfactorily without any attention. It is mostly in wall trees, &c., where a heavy system of annual pruning, or rather lopping off, is practised, that the worst results are observed. By taking up the trees quite out of the ground, and root-pruning them, the useless vigour of the tree is checked, and its energies turned from the production of willow-like shoots to delicious fruit. In numerous cases I have seen an abundant crop of fine fruit produced by Pears and Plums the very season after this root-pruning had been performed, upon trees from which nothing had been gathered for years previously. The result is nearly always satisfactory, and common sense would lead one to expect it. Poor soil induces vegetable life to devote its energies to the production of fruit and seed, while stature and luxuriance can only be secured by liberal treatment.

We may observe how, on poor sandy soils, some of the common annual weeds become a mass of inflorescence and fruit, while on rich ones they are green, fleshy, and comparatively flowerless. Of course, it would be very unwise to apply this principle of moderation in rich food to things that we want to furnish leaf and stem and succulence to the kitchen—Asparagus, Rhubarb, Celery, &c., to wit; but it must be practised in the case of fruit trees. The way to root-prune these barren subjects is to first dig a semi-circular trench at about the distance to which the outer roots are supposed to extend, using for this purpose those elastic and slender-tined forks which have so much facilitated such operations of late years—Park's forks, as they are usually called. A spade would of course cut off the fibrous roots everywhere it met them. When the trench is sunk as low as the roots (in old plants which have gone deep it may require to be sunk 3 feet), the operator must work in towards the stem of the tree, undermining the roots and turning them back as he goes on, till the base of the stem is reached, and the tree taken up as carefully as possible. Then the very strong roots must be shortened or cut off; but the mere taking up of the tree does nearly all that is necessary in this way, as those roots (if any) that go straight down are destroyed when the tree is taken up; their stumps, however, should be cut out, retaining all the roots that have a spreading tendency and a disposition to remain near the surface. This effected, level in the ground again, and lay a few barrows of chopped turfy loam over the surface on which to place the roots, arranging the whole so that the roots will be little, if at all, below the level of the surrounding ground. When the specimen is placed in position, and the roots laid out naturally, a little more of the good turfy loam must be laid over the roots, and over that some of the ordinary soil of the border. Leave the tree loosely supported against the wall till it has sunk as far as it is likely to sink. It would be well to make the ground pretty firm before planting, and thus prevent this after-sinking to a great extent. Root-pruning has various phases, but these remarks apply chiefly to those large, old, and vigorous but useless trees so often seen in gardens. V.

### VARIATION AMONG FRUITS.

HORTICULTURISTS frequently find among cultivated fruits and flowers strange variations from the original or normal types of varieties, and these are termed freaks or sports. When we raise fruits or plants of any kind from seed, we expect that the seedlings will vary more or less, for it is by this process or mode of propagation that most of the varieties in cultivation have been produced. Varieties usually remain unchanged, during any number of generations, the same as species, and we go on propagating them by the usual methods, such as grafting, budding, or cuttings, confident of preserving their distinct and peculiar characteristics. But during the course of propagation, which often extends through many centuries, it would not be strange if there should occasionally occur causes sufficient to produce a marked change in the general habit of some one individual plant among the many thousands. That certain "sports" or variations have appeared among all of our leading and more commonly cultivated fruits, is well known to every pomologist. The causes are generally unknown, and we can only guess what they might have been from the little we know of the structure of plants. The boring of an insect into a twig may cause the leaves upon it to change from their natural to some other colour, and should this continue more than one season, the peculiarity may become partially fixed, and by propagating from the injured twig the nurseryman stands a chance of perpetuating the "sport." Sometimes a change in soil, climate, culture, diseases, or insects produces a marked effect upon the fruit of a tree; so much so that those well acquainted with the variety in other localities will fail to recognise it, and when trees are under these extremely favourable or unfavourable conditions they are likely to produce what are termed bud variations, that is, a single bud will produce a shoot varying from others on the same tree, either in the form of leaf, habit of growth, and sometimes it extends to the fruit, which will be very distinct from that on other branches of the parent tree. These bud variations are extremely rare, at least those of such a marked character as to attract the attention of pomologists, but an occasional one appears, and is perpetuated by some one of the various modes of propagation. Curious sports also appear among seedlings, and they are probably far more common than sports among well-established varieties; but as the seedlings of fruit trees are mainly raised for stocks, few survive or come to maturity, and it is only among the old seedling Apple, Pear, and Plum orchards that we find specimens to support and prove our theory, that sports occur among these fruits, as well as among ornamental trees, shrubs, and other plants.

#### SWEET AND SOUR APPLE.

This is a very old variety, and its origin is unknown. The fruit is large, oblate in form, somewhat ribbed, colour green, not unlike the Rhode Island Greening; but, when it begins to ripen, the ribs remain green and the spaces between them yellow. The green portions are quite acid, the yellow sweet or almost flavourless—hence the name. Sometimes the sweet and sour portions will be in alternate quarters; in others, one-half of the Apple will be sour and the other half sweet, scarcely any two specimens from the same tree being exactly alike in this particular. Now, there has been more than one claimant for the honour of producing this variety, and the boldest of them have asserted that it was produced by uniting two halves of two buds or grafts, one being taken from a sweet Apple tree and the other from a sour. In the first place, any such result as claimed from such a union is an impossibility, and no man knowing anything of vegetable physiology would talk in this nonsensical manner; because, even one-half of the smallest bud, with sufficient wood attached to ensure its growth, would contain hundreds of plant-cells, each of which is capable of perpetuating the individual characteristics of the parent stock. If a bud or scion were made to unite and produce a branch, every bud and twig on either side would remain true to the parent stock, and there could not be any intermingling or conglomeration of the cells or their contents. Scientific pomologists have tried such experiments over and over again; then why should any one believe that an ignoramus in such matters could or did succeed. But the ripening of the fruit destroys and contradicts this story of dividing the bud or scion in halves to produce it, because the sweet and sour portions are seldom found in this form. This variety is only one of the innumerable "sports" among Apples, and has been perpetuated more as a curiosity than for its intrinsic value.

#### FLOWERLESS AND SEEDLESS APPLES.

Several times within the past few years Apples have been shown which contained no seed, and it was also claimed that the trees never produced any flowers. But the specimens exhibited had upon them the usual shrivelled calyx which is the essential part of an Apple blossom. There were also pistils plainly to be seen, consequently these facts proved that the Apple tree which produced the fruit shown did bloom. It is quite probable that the petals, which

are the most showy part, but least essential, were either very small, deformed, or entirely wanting. The pistils, stamens, or ovaries, may have been deformed, hence the absence of seeds, the same as we find in many of our largest and best developed sorts. The flowerless Apple tree producing fruit is, therefore, a misnomer. The Apples mentioned above came from Pennsylvania, and were considered a great novelty, not only by the owner of the tree, but by many members of the press, judging from the notices this variety has received. It happens, however, to be no novelty either in this country or abroad, as such sports have often appeared. In the Annals of the Linnean Society of Paris for May, 1824, M. Tillet de Clermont described a similar variety found in Normandy. The tree was then supposed to be about forty years old, and it had constantly produced flowers composed of an external and an internal calyx, pistils, but neither stamens nor corolla (petals). The fruit was even more wonderful than that from Pennsylvania, for the Apples were said to vary in size, colour, form, and flavour.

#### OTHER SPORTS.

Apples which never produce seeds, or possess scarcely any trace of a core, have been found in various localities. The trees produce showy blossoms in some instances, but the pistils as well as ovaries are deformed. These may be placed among the permanent varieties which originated from seed, and not among the bud variations, springing from branches of other sorts. Perhaps the most curious sport discovered within the past few years is that of a tree which had always borne a very smooth green Apple, suddenly producing upon one of its branches beautiful russet fruit. In some instances one-half of a specimen was russet, and the other half smooth, the line of demarcation between the two being as clearly defined as though struck in a lath. The branch has produced this kind of fruit two years in succession, and it is quite probable that scions from it would perpetuate the sport. Many other sports among Apples might be named, but I think enough have been mentioned to show that such things are neither novel nor new.—A. S. Fuller.

#### VINES ON OPEN WALLS.

AN article by "B. S.," in THE GARDEN, page 75, on "Growing Vines on Open Walls," is so much to the purpose that I wish to add a few more varieties to his list, which I have found, in practice, adapted for the purpose. There is no doubt that, in ordinary warm summers, good Grapes can be ripened on open walls, either fit for the dessert or for making wine. A selection, however, of the earliest ripening varieties is required for this purpose, and I have found the following the best, namely, for white sorts—the Malvasia, synonymous with Grove-end Sweetwater and early Kienzheim, of the Horticultural Society. This is the earliest ripening white Grape I have grown. The Precoce de Malinre is the next in earliness, to be succeeded by the Royal Muscadine, named the Chasselas de Fontainebleau by the French, and the early Smyrna. Of Black early Grapes, the old Miller's Burgundy is, perhaps, the earliest for ripening, but the bunches are small and worthless, except for wine making. The Chasselas Noir is the earliest good black Grape; Sarbelle, a small rich Grape of the Frontignan section, and which ripens early, to be succeeded by the Esperiole, the best black early Grape for the general crop. As the soil and borders have a great effect on the success of growing Grapes in the open air, some attention should be paid to have the borders properly made when the Vines are planted. Where the subsoil is strong and damp, the bottom of the border should be concreted, or filled up with old broken bricks and lime rubbish, or ashes, and the soil used any light calcareous soils from the roadside or commons, with any good light loamy or sandy garden soil. The Vines ought to be planted on mounds, so that additions could be made to them by manurial materials from time to time. There are other situations for growing early Grapes on, which are often disfigured by growing worthless fruit trees or creepers on them, namely, the south aspects, on cottages and farm buildings. There is not a more cheerful and graceful plant than the Vine when in full leaf; and when loaded with its ripe, luscious bunches in very warm summers (which, alas! only seldom occur), there is no fruit tree in the open air to compare with it; the only drawback to its culture in the open air is when the fruit begins to get ripe, that wasps, blue-bottle flies, and birds require a deal of attention in preserving the bunches from their ravages. From "B. S.'s" experience with muslin bags, which preserved the bunches of his Precoce de Malinre, cultivators can always have a chance of saving their crop. With a good crop on a wall, however, some breadths of the Nottingham hexagon netting spread over the bunches would answer the same purpose, and take less trouble in fixing it than making muslin bags. WILLIAM TILLERY.

**Influence of the Stock on the Produce of the Scion.**—M. Decaisne (see page 133) is wrong in stating that fruits are unin-

fluenced by the stocks on which they are grown. As a striking case in point, I would cite the change effected in the size and earliness of Muscat Grapes by being grafted on the Trebbiano, as seen at Trentham. I have also seen the Madresfield Court modified in colour, form, and quality by being grafted on a white stock. I commend these facts and others of a similar kind pertaining to Apple stocks to the notice of M. Decaisne and others who think with him that the stock has no power to ameliorate or alter the character of fruit.—D. T. FISK.

**Variations in regard to Pears.**—In France alone about 800 sorts of Pears can be counted the origin of most of which is unknown, and many are undoubtedly very ancient. Indeed, according to Jordan and his school these differences are primitive, and the so-called races and varieties, both of wild and cultivated plants, represent so many closely related species. M. Decaisne, not content with the *reductio ad absurdum* of having about 2000 species of Pears to be dealt with, proceeded to an experimental demonstration of the variability of the cultivated races. He sowed the seeds from four very distinct varieties in 1853, the Poire d'Angleterre, Benrre Bosc, Belle Alliance, and the Crole. Of the last the four trees raised bore fruit of four different forms. From the Belle Alliance he obtained, in this first generation, nine new varieties, none of them representing the parent, neither in the form, size, colour, nor even the time of ripening of the fruit. The Benrre Bosc equally produced new varieties. Of the Angleterre nine trees produced as many new forms, one of them a winter Pear similar to the Saint Germain, another Apple-shaped fruit identical with one which was raised from the Belle Alliance.

**No Profit in Dwarf Pears.**—We take the following from a letter in *The Country Gentleman*, descriptive of the fruit farm and practices of D. W. Coit, of Norwich, Connecticut:—"Dwarf Pears have been very thoroughly tested by Mr. Coit, in an experience of twenty years, and are a failure except for amateur purposes. They bear much earlier than standards, and the fruit is quite as large and well flavoured. But unless the roots strike out from the Pear wood above the Quince roots, they do not grow very large, and they fall early. They cannot be relied upon to give large crops. If one wants a Pear orchard to supply the market, he should plant standards, and give them plenty of room. This statement, coming as it does from one of the oldest and most careful cultivators in New England, is worthy of the thoughtful consideration of those of the Eastern States who purpose planting Pears for profit. Mr. Coit's experience is similar to that of thousands who have been induced to select dwarfs instead of standards. Charles Downing, the veteran horticulturist, whose name is known wherever fruit is grown in this country, gave years ago his ripe judgment against this dwarf fallacy, and each season's experience serves further to show how far-sighted Mr. Downing was in his prediction. It will, no doubt, take many years to convince the public that it is labour and money thrown away to plant dwarfs in the orchard, but the constantly-increasing current of testimony in that direction must tell in time."

#### NOTES AND QUESTIONS ON THE FRUIT GARDEN.

**American Gooseberries.**—The *Horticulturist* of New York figures in its January number some varieties of American Gooseberries which seem distinct from our own, and would appear to merit a trial in this country.

**Juglans nigra.**—A Michigan farm of 80 acres is surrounded by a gigantic hedge of black Walnut trees (*Juglans nigra*). Would it not be well if useful instead of useless plants or trees were used in similar positions?

**Moss on Fruit Trees.**—Simpler and equally efficient in removing Moss from fruit trees as carbolic soap and lye, is a whitewash made of hot lime and water, as used by Mr. Carmichael, late of Sandringham, and others. Whenever and wherever a spot of Moss or patch of Lichen appears one dab of this simple whitewash removes them.—D. T. FISK.

**Syringing Peach-trees while in Bloom.**—This has been an exceptionally dull season for the "setting" of early Peach crops, but by keeping up the temperature by fire heat, and syringing the trees every second day in the afternoon with clean tepid water, we have got a perfect smother of fruit that will require much thinning.—J. S. W.

**A Devonshire Custom.**—A curious custom was formerly observed, on the eve of the Epiphany, by the farmers and their labourers in the south of Devonshire. The ceremony alluded to consisted in the men repairing to the orchard, where, encircling one of the most fruitful trees, they drank the following toast three times:—

Here's to thee, old Apple tree,  
When thou mayst bud, and when thou mayst blow!  
And when thou mayst bear Apple enow!  
Hats full! caps full!  
Boshel—boshel—sacks full!  
And my pockets full too!  
Huzza! Huzza! Huzza!

**Inducing Pines to Show Fruit.**—The best matured plants, especially Queens, will, as a rule, fail to show fruit if started with a high top and bottom heat at the first. 75° bottom temperature, and 70° minimum and 80° maximum tops should never be exceeded till the fruit is visible, when 5° may be added to these respectively. I have known a whole house of Pines lost through neglecting these precautions in the anxiety to hurry fruit forward.—W.

## GARDEN STRUCTURES.

## THE IMPROVED CURVILINEAR PEACH HOUSES.

AMONG the various exhibits at Birmingham last year in the way of glass structures, few had a more elegant or pleasing appearance than the curvilinear houses, shown there by Mr. Perry, of the Nurseries and Horticultural Building Works, Banbury. These houses are built of wood, and glazed with 21 oz. sheet glass, connected with strong cathedral lead, the roof at a few paces distant presenting the effect of a plain surface of glass; this, with their curved outline, makes them look extremely light, while the maximum of light is admitted, and freedom from drip and cold draught secured. In the ordinary style of building the value and preservation of the structure mainly depends on its being frequently and thoroughly painted, thus entailing considerable outlay, and often causing great inconvenience. In the improved curvilinear roof there is only a portion of the woodwork in the ventilating apparatus exposed to the weather; therefore, outside painting, with this exception, is dispensed with. These houses are not only suitable for Peaches, but are equally well adapted for Vine and fruit-growing generally.

## TERRA COTTA STOVES.

My foreman having alluded to these valuable stoves in a late number of THE GARDEN, I beg to say that I can fully endorse the truth of his statement. My experience with this kind of stove is sufficiently ample to justify my recommending it as the best and cheapest portable stove with which I am acquainted. Last year one of my boilers at Enville gave way in the Orange-house; I ordered one of these stoves to keep up the heat during the time the boiler was under repair, and it did its work so well as to far exceed my expectations. The same stove was afterwards used to heat a large schoolroom, and it gave equal satisfaction. The consumption of fuel is so small that 3d. would keep it at work from sixteen to twenty-four hours, and the attention which it requires is really nothing. It may be left for sixteen hours or more with perfect safety. No fumes of any sort escape from it, and it may be used in any plant-house without fear of injury to the most delicate plants; between the terra cotta and outside case it is packed with sand, so that in using common fuel no smoke can escape. Just as the late frost set in I had the misfortune to lose an old boiler which warmed my early Vinery at Hatfield; I therefore at once started off and bought one of these stoves, hurried home, got the stove set at work, and saved my early house of Grapes, then about the size of Peas. This little stove so astonished every one by the little attention which it required, and the great length of time during which it imparted heat with once filling the bucket, that my foreman determined to try how long it would burn without replenishing it with fresh fuel. His only attention was to keep a check upon the draught, and he has already stated in your columns that for forty-six hours it imparted heat. The price of the stove is 5s., and those with moveable tops are by far the best. This should be particularly stated when ordering these stoves.

Whilst on the subject of stoves, allow me to direct attention to one of the best of portable stoves for heating hot-water pipes that perhaps has ever been invented, viz., Deards' Patent Amateur's Heating Apparatus, to which a medal was awarded at Birmingham. Of these I have one at work, which heats a house of considerable dimensions in the most satisfactory manner. This stove can be removed from house to house if necessary. It requires no fixing, being simply placed on a stand of bricks. The joints of the pipes being made with india-rubber rings, can quickly be pulled to pieces and can as quickly be put together again. Indeed, the whole apparatus may be taken down and put up to work again in a couple of hours. To those who require a small apparatus to heat Cucumber houses, or greenhouses, &c., and one that requires but little attention, and the smallest consumption of fuel, these stoves are really invaluable. All who have a greenhouse should possess one; indeed, every gardener who has any quantity of glass would do well to have one by him, in case of need, for we never know when a boiler may collapse. The water space of these stoves consists of a continuous coil of pipe, either large or small, according to the requirements, completely surrounding the fire. From 100 to 150 feet of hot-water piping may be heated for about fourpence per day, the stove burning from eight to twelve hours without attention. Roberts' Patent Terra Cotta I consider the best and cheapest portable dry stove, and Deards' Patent Centrifugal Heating Apparatus the best and by far the cheapest stove for heating hot water that has yet ever been invented.—EDWARD BENNELL, *Gardener to the Marquis of Salisbury, Hatfield, Herts.*

## THE KITCHEN GARDEN.

## THE VARIETIES OF THE GARDEN PEA.

## I.—FRAME PEAS.

**Dillistone's Early** (*Carter's First Crop; Sutton's Ringleader; Clarke's Rapid Prolific*).—The plant is of a slender habit of growth, producing a simple stem 2 feet high, bearing on an average from seven to nine pods. These are generally single, but occasionally in pairs, almost straight, and containing seven Peas in each. The ripe seed is small, smooth, and white. This is the earliest of all the white-seeded Peas, and with the exception of Mr. Laxton's Harbinger, is the earliest known. When this variety first appeared, twelve or fourteen years ago, and before it had been allowed to degenerate, it was far in advance of every other variety. Sown on the 19th of February, the plants were a mass of bloom on the 19th of May. On the 5th of June the blooms dropped and the slats appeared, and on the 22nd of June the whole crop was ready to be gathered. At that period it was quite seven to eight days earlier than a perfectly pure stock of Sangster's No. 1, which up to that time had been regarded as the earliest of all. A striking feature of Dillistone's Early is, when pure, that the plants are all of a uniform height; they bloom in a mass, the pods all appear together, and the whole crop is ready to be gathered at the same time.

**Sangster's No. 1** (*Daniel O'Rourke; Carter's Earliest; Dickson's First and Best; Sutton's Champion; Sutton's Improved Early Champion; Dickson's Climax; Washington; Isherwood's Railway; Early Carroticus; Taber's Perfection; Hooper's Early Rival*).—This variety is of a slender habit of growth, more so than early Emperor, and consists of a single stem 2 feet high, producing, on an average, from eight to ten pods on each plant. Pods generally single, but frequently in pairs, 10 $\frac{3}{4}$  inches long, and upwards of half an inch wide, quite straight, thick and plump, and terminating abruptly at the point. When fully grown they become much swollen, broad in the back, and somewhat round or quadrangular. They contain, on an average, seven, but frequently eight Peas. The ripe seed is white. This and Waite's Daniel O'Rourke were sown in adjoining rows 5th of April, 1853, and came into bloom on the 5th of June; on the 9th the first blooms began to drop, and the slats (young pods) to appear; by the 22nd the whole plants were nearly out of bloom; and on the 1st of July the pods were quite filled and ready to gather. I was most particular in my observation of these two varieties, as it had been said by some that they are distinct. That there should be no mistake I procured Sangster's No. 1 from Mr. Sangster, and Daniel O'Rourke from Mr. Waite. They were sown on the same day, came up on the same day, slatted on the same day, podded on the same day, and died off on the same day, after having attained the same height, and presented the same habit of growth. This is a very valuable Pea. It is not so tall by some inches as Emperor, stops growing and blooming much sooner, and is ripening off when Emperor is still fresh and growing. In this respect it is very valuable to the gardener, as it enables him, after obtaining a prolific crop of early Peas, to clear the ground for something else. It comes into use seven days later than Dillistone's Early, and matures its crop more slowly.

**Early Kent** (*Early May; Prince Albert*).—The true Early Kent is now almost, if not quite, out of cultivation, and deservedly so, its place having been occupied by Dillistone's Early, a more prolific and an equally early Pea. It is of a very slender habit of growth, and rarely more than 2 feet high, producing a scanty crop of small ill-filled pods. Its only recommendation, even in its best days, was its earliness. It was this variety which was formerly grown extensively at Higham, in Kent, a very early locality, from which the first Peas of the season came into the London markets.

**Taylor's Prolific**.—The pods are all strictly single, and are of the size and shape of Sangster's No. 1, containing on an average from six to seven Peas in each. The plant is 2 feet high, and produces perfect pods even to the top of the haulm, when the whole ripen off simultaneously. Taylor's Prolific seems to be a very superior variety of the old Early Kent, from which it has, no doubt, originated.

**Early Emperor** (*Early Sebastopol; Morning Star; Rising Sun; Warner's Conqueror; Warner's Emperor*).—Plant of a slender habit of growth, always with a single stem, which is 2 $\frac{1}{2}$  to 3 feet high, and produces from eight to ten pods on each plant. Pods generally single, but frequently in pairs, from 2 $\frac{1}{2}$  to 3 inches long, perfectly straight, and terminating abruptly at the end. They are well filled, and contain from five to seven Peas, which are roundish and flattened, seven-twentieths of an inch long, six-twentieths broad, and the same in thickness. The ripe seed is white. The seed was sown on the 5th of April, 1851, and the plants came into bloom on the 5th of June; the blooms began to drop on the 9th, and on the 1st of July the pods were completely filled and ready to gather.

**Ruelle Michaux**.—This is a very inferior stock of Early

Emperor, having short broad pods, and coming into use at the same time.

**Danecroft Rival** (*Girling's Pea*; *Glass Pea*).—This can be easily distinguished from every other variety by the total absence of glaucescence or bloom on the leaves, which gives it a singular and sickly appearance. The plant is from 2½ to 3 feet high, of slender habit of growth, and consists of a simple stem. The pods are produced singly, and are from 2½ to sometimes 3 inches in length, perfectly straight, and terminated abruptly at the end; being in

to eight Peas. Sown the same day, it ripens two days later than Early Emperor. The variety is not worth growing.

**Early Ringwood** (*Ringwood Marrow*; *Flanagan's Early*; *Beck's Marrow*; *Essex Rival*).—This produces a very large well-filled pod, and is a most abundant bearer; but it has a peculiarity, which, by some, is considered an objection, from the pod being white instead of green, and presenting, when only fully grown, the appearance of over maturity. This objection, however, is chiefly taken by those who grow it for market, and who find a difficulty in convincing their

The Improved Curvilinear Peach Houses.

every respect similar to those of Warner's Emperor. They contain, on an average, seven Peas, but occasionally eight. The ripe seed is white. This, though an early Pea, and coming in almost as soon as any of those already described, is not a desirable variety for general cultivation. It is much less productive, and considerably more tender. This was raised about thirty-five years ago by Mr. Girling, of Stowmarket.

**Sutton's Emerald Gem** (*Sutton's No. 1 Green*; *Sutton's First of All*; *Sutton's Earliest of All*).—This bears a near resemblance to and has the same habit of growth as Danecroft Rival, and, like that variety, is destitute of the glaucescence which all other Peas possess; it comes into flower two days earlier than Danecroft Rival and is fit for use at the same time, being four days later than Dillistone's Early.

**Beck's Gem** (*Tom Thumb*; *Turner's Royal Dwarf*; *Nain hâtif extra*; *De Grave*).—This is the most dwarf-growing of all the varieties. It rarely ever exceeds a foot in height; the stem is of a stout habit of growth, and branches at every joint to within three or four of the top, producing from fourteen to eighteen pods. The pods are almost always borne in pairs, rarely singly, and are produced at every joint, particularly towards the top; they are smooth, of a dark green colour, and well filled, containing from five to eight Peas, which are almost as large as Imperials. The ripe seed is greyish pearly colour. This is a very excellent Pea for forcing, and for early sowing under walls or other shelter. It is remarkably prolific, and cannot but be of great use in small gardens where sticks cannot be conveniently obtained or made use of. This ripens at the same time as Early Emperor.

**Telegraph**.—This is in every respect, as regards habit of growth and general appearance, similar to the Early Emperor, and differs from it in the ripe seed having a black hilum like the Egg Pea. It also partakes of the character of the Egg Pea in flavour, having the rough Bean-like taste which is remarkable in that variety. It produces, on an average, five to eight pods on a stem, and these contain from seven

customers that, notwithstanding the pod being white, it is still not over-ripe. So far from being out of season, the Ringwood Marrow retains its tender and marrow character longer than many other varieties. Plant with a moderately vigorous habit of growth, producing a stem which is 3½ to 4 feet high, and always simple except in wet seasons, when it makes a second growth by throwing out shoots from near the ground. The lowest pods are within about a foot of the ground, and are produced at every joint, even to the extremity, the whole number on each plant being from ten to twelve.

The pods are single and in pairs, in about equal proportions, from 3 to 3½ inches long, and six-tenths of an inch wide, slightly curved and waved on the upper margin, and terminated rather abruptly at the point. As they ripen they become thick and fleshy, with a rough, pitted and shrivelled surface. They contain from six to seven large Peas, which are roundish and not compressed, about nine-tenths of an inch long, seven-tenths wide, and the same in thickness. The ripe seed is white. It comes into use six days later than Sangster's No. 1.

**Early Warwick** (*Race-horse*; *Essex Champion*).—What is now grown under the name of Early Warwick is very different from the variety to which the name was originally applied. When first obtained at Evesham, in Warwickshire, it was a single-blossomed Pea, and somewhat earlier than the double-blossomed Frame of those days, but it gradually lost its single-blossomed character, and has now become in all gardens with which we are

acquainted identified with the ordinary Early Frames.

**Early Frame**.—In adopting the name "Early Frame," I mean to include all the forms known under that name, whether they are called single or double-blossomed, for in fact there are none that are absolutely single or absolutely "double-blossomed." These expressions are not meant to indicate any peculiar structure of the flower as regards the number of petals, but merely that the blossoms are produced singly or in pairs on the same peduncle. Great efforts have from time to time been made to preserve the single-blossomed

Interior View.

character, and notwithstanding the care that has been bestowed upon the selection, growers have hitherto failed in rendering it permanent. There is however, no real advantage to be obtained, even if that character were secured, for the supposed earliness of the single-blossomed Frame Peas is now far exceeded by other varieties that have been introduced of late years.

**Dickson's Favourite** (*Dickson's Favourite Improved; the Wonder; Cottrell's Wonder; Turwoodlee*).—This seems to be a form of the Auvergne, but the plant has a more slender growth than that variety, and it is a day or two earlier. It grows from 4 to 5 feet high, with single stem, and pale green foliage. The pods are produced in pairs to the number of twelve or fourteen, and are curved, but not so much so as in the Auvergne, and contain from six to seven Peas in each. Ripe seed white. This variety, like the Auvergne, has a strong tendency to degenerate, and to lose its distinctive character, and therefore requires to be closely selected to preserve the stock in a state of purity. It is decidedly an inferior Pea to the true Auvergne, which it resembles, and which produces long, curved, well-filled pods containing from nine to twelve Peas in each.

**Leopold II.**—This bears a close resemblance to Early Ringwood, the foliage and pods being of the peculiar pale green colour of that variety. The pods are long, narrow, nearly straight, very badly filled, the middle Pea in each pod being abortive. It is two days later than Early Ringwood.

**Bishop's Long-podded** (*Bishop's Improved*).—The old Bishop's Dwarf is now entirely out of cultivation. It was a low-growing plant, 9 inches to a foot high, with a branching stem, and produced small insignificant pods  $2\frac{1}{2}$  inches long and half an inch wide. Such a Pea is of no use in these days. Bishop's Long-podded is a great improvement on the old variety. It grows about 2 feet high, produces numerous branches, and bears from eighteen to twenty pods on a plant. The pods are either single or in pairs, and contain from seven to nine Peas in each. Ripe seed creamy-white.

**Sutton's Long-podded Tom Thumb.**—At the trial of Peas held in the garden at Chiswick this season, the Committee decided that this was identical with Bishop's Early Dwarf.

**Carter's Farmers' Prolific.**—Plant with a strong and robust habit of growth, 5 to 6 feet high, producing fourteen to sixteen pods on each stem, which are narrow, and very closely filled with six or seven small Peas. It is a very prolific variety, and comes into use about the same time as Dickson's Favourite and Auvergne.

**Spanish Dwarf** (*Dwarf Fan; Dwarf Boy*).—This is an old and worthless variety. The plant is about a foot high, branching out on each side in the manner of a fan, and hence it is called the Dwarf Fan. The pods are either single or in pairs, from 2 to  $2\frac{1}{2}$  inches long, and about half an inch broad, terminating abruptly at the point, and containing from five to six rather large Peas. There is a variety of this which is called the Improved Spanish Dwarf, and grows fully 9 inches taller than the old variety, but it possesses no particular merit to recommend it.

**Glory of Cassel** is similar but inferior to Auvergne, and is about two days earlier.

**Auvergne** (*White Sabot; White Scimitar*).—The Auvergne Pea was introduced from France some years ago by the Royal Horticultural Society, but although it very far surpassed every other variety of White Pea then in cultivation, it never became widely known or generally cultivated. It is a most characteristic variety, and always easily distinguishable by its long and curved pod. The plant is of a moderately strong habit of growth, producing a single stem from 4 to 5 feet high, according to the soil in which it is grown, and bears from twelve to fifteen pods on each. The pods are generally small, but sometimes in pairs; when fully grown,  $4\frac{1}{2}$  inches long, and over half an inch broad, tapering towards the point and very much curved; they contain from nine to twelve Peas, which are very closely compressed, and are the size of the Early Frames. Even the small pods contain as many as from seven to nine Peas in each. The ripe seed is white. It is four or five days later than Early Ringwood.

**Shilling's Grotto.**—The plant is of a strong habit of growth, always with a single stem  $4\frac{1}{2}$  to 5 feet high. The pods are generally single, but frequently in pairs,  $3\frac{1}{2}$  inches long and about half an inch wide, and containing on an average about seven large Peas. The ripe seed is white. It is thirty years since this Pea was introduced, and at that time it was a decided acquisition, being a great improvement on the second early varieties then in cultivation. Since the introduction of Champion of England, Champion of Paris, Prizetaker, and several others to which it is certainly inferior, and which ripen at the same time, it may very well be dispensed with. It ripens at the same time as Auvergne.

**Charlton.**—It is a hard matter to say what the Charlton Pea is now a-days. The old variety, which was so long known under that and a dozen other names, having disappeared, the Charlton Pea, as a

variety, exists only in name. For very many years it was the most extensively cultivated and the most highly esteemed of all the varieties then known. It was the earliest and the best, and the care bestowed on the growth and selection of the stock was as great as is now exercised on that of Emperors or Number Ones. The same propensity for the multiplication of the names of a good thing seems to have been as great in former ages as in this; and hence we find Charltons and Hotspurs with designations almost as numerous as the names of the persons who grew them. The original name of the Charlton Pea was Hotspur, still used by some, and by contraction Hots; or, rather, it may be that Hots is the original, for I have somewhere read, in an old author, the word "hot" made use of in the same sense as we do "early." I do not know at what period this variety first became known; but I can trace it as far back as the year 1670, and from that period till about 1770, or as nearly as possible for one century, it continued to stand first in the list as the earliest Pea, until it was supplanted by the Early Frame about 1770. The various names by which it was known during the last century were Reading Hotspur, Masters' or Flander's Hotspur, Golden Hotspur, Brompton Hotspur, Essex Hotspur, Omerod's Hotspur, Early Nichol's Hotspur, Charlton Hotspur, and, finally, Early Charlton. The last name became general about 1750. There can be no doubt that these names were applied much in the same way as we have described under Early Frame, and that the varieties were distinguishable according to the care with which the growers selected them. Masters' Hotspur, which is still retained in some catalogues of the present day, was so called from a person of that name, who, it is said, selected it, and who was a nurseryman at Strand-on-the-Green, near Brentford, 140 years ago. It has also been called Hastings, Marquis of Hastings, and Essex Readings. It is not in our power to furnish a description and a figure of this variety, for, as we have said, there is in reality no such thing as the Charlton Pea in existence. That which is sold for Charltons is any degenerated stock of Early Frames, or any stock of Frames which cannot be warranted or depended upon, but which are, nevertheless, of such a character as to admit of their being grown as garden varieties. Let writers on gardening, therefore, be careful in future, when called on for a list of Peas, not to give, as is often done, the Charlton as "the best second early." There is no distinct variety grown for Charltons by the seed-growers.

**Dwarf Waterloo Branching.**—This closely resembles Bishop's Long-podded, but is two days earlier. In other respects there is really no difference.

**Nabob** (Laxton).—This was raised by Mr. Laxton from a cross made between Little Gem and Laxton's Prolific Long-pod. The plant is 18 inches to 2 feet high, strong and robust in habit, with large dark green foliage. It produces from ten to twelve pods, which are long and curved, of a deep green colour, and containing from seven to nine medium-sized pale green Peas. This is the largest and most handsome of the dwarf early white Peas, and it is exceedingly productive.

**Royal Dwarf** (*White Prussian; Poor Man's Profit; Dwarf Prolific*).—Plant of medium growth, with an erect stem, which is 3 feet high, generally simple, but occasionally branching. The pods are sometimes single and sometimes in pairs, but generally single, and from  $2\frac{1}{2}$  to 3 inches long, half an inch broad, almost straight, and somewhat tapering to the point; the surface is quite smooth, and the colour bright green. They are generally well filled, and contain from five to six Peas, which are somewhat ovate, not compressed, eight-twentieths of an inch long, seven-twentieths broad, and the same in thickness. The ripe seed is white. The seed was sown on the 5th of April, and the plants bloomed on the 26th of June. The blooms dropped and the slats appeared, and on the 16th of July the pods were fit to be gathered. This is an old and very prolific variety, well adapted for field culture, and long a favourite in gardens, but now superseded.

**Clamart.**—The plant is very vigorous, and in its habit much resembles Early Emperor. It grows late, and maintains its fine green foliage to the last. Pods generally in pairs, produced in succession, from sixteen to eighteen on each stem, and containing from six to eight Peas each. It is a week later than Early Emperor.

**Peabody.**—This is of a dwarf, bushy, and compact habit, and the leaves are rather small, numerous, and of a bright green colour. The stem is  $2\frac{1}{2}$  feet high and branching. Pods rather narrow, small, and extremely well filled, deep green, and containing from six to seven rather small Peas. This is a very productive variety, and stands the dry weather well, but is of inferior quality. It is eight days later than Auvergne, and five days later than Royal Dwarf.

**Victoria Branching** (*Paul's Early Dwarf; Paul's Prolific*).—Plant with a strong robust habit of growth, 3 feet high. The stem is generally simple, but sometimes branching, and bears from twelve

to sixteen pods, which are 3 to 3½ inches long and half an inch broad, and contain from seven to eight large Peas. The foliage is dark green. Ripe seed white. This is a very abundant bearer; it is three days later than Royal Dwarf.

**Crown (Bunch; Cluster; Mummy).**—This is a very characteristic variety, known at once by producing its pods at the extremity of the stem in a bunch or tassel. The plant is ½ to 5 feet high; the stem gradually increasing in thickness from the root upwards, in some instances to the thickness of a man's thumb, when it becomes quite dilated, producing twenty-four to thirty pods in a bunch. These are small, round, and well filled, in appearance like those of Early Emperor, and containing from four to seven small Peas. Ripe seed small, round, and white. This enrious but useless Pea, sown on the 23rd February, first bloomed on the 16th of June, and was in full bloom on the 17th. The slats appeared on the 21st of June, and the crop was ready for use on the 1st of July.

(To be continued.)

### ONIONS.

ONE of the best cultivators of Onions I ever met with invariably grows them on the piece of ground which previously contained Celery. As the Celery is cleared away, the ground is trenched to the depth of 2 feet or thereabouts, according to the depth and fertility of the soil; and, his ground being a little stiff, he adopts the practice of throwing the rotten dung from the bottom of the trenches to the top. In dry, frosty weather, when the ground is frozen to the depth of 4 or 5 inches, the frozen lumps are beaten to pieces with a mattock, and the surface of the ground left rough. About the last week in February or the first week in March, according as the weather proves dry and favourable, the ground is slightly forked over and the surface left as level as possible. In the course of a week pigeons' dung is thinly spread over the surface; and, should the ground be damp, in addition to the pigeons' dung, some charcoal dust is added, in order to make the ground work as freely as possible. The charcoal is also considered a fine manure for the Onion. Then the manure is forked in and the ground raked as level as possible. The seed is sown in drills one foot apart, and they are not divided into beds, as it is thought to be a waste of ground if provision be made for paths. As soon as the plants are well through the ground, the hoe is used between the rows, and any weeds that may have put in appearance among the plants are removed by hand. As soon as it can be done, thinning out is proceeded with, and the plants are left from 1 to 5 inches apart in the rows; and subsequently hoeing and hand-weeding are continued as often as requisite. Grown in this way, fine symmetrical bulbs are formed, with but a very slight admixture of a coarse thick-necked type, for seed is saved only from the best-developed bulbs. When the crop is fully ripe, it is pulled up, and after lying on the ground for a few days they are brought into a shed to finish drying. In a wet season they are put into a frame orinery to dry, or into a Mushroom house where a little fire is kept on, in order to get them thoroughly dry, as the keeping of them entirely depends on this. A few are always selected for exhibition purposes. In dry weather these are helped with a little weak liquid manure, and as the neck begins to swell they are pinched by the pressure of the finger and thumb, so as to throw the strength of the plant into the formation of the bulb, and to secure that desired fineness of neck so requisite on the exhibition table. In this way it is not unusual to have twelve tubers weighing collectively from 12lb. to 15lb. R. D.

**Wintering Cabbages.**—Persons interested in the preservation of Brassicaceous crops from great cold may find the following account of how that can be effected suggestive. Cultivators near Philadelphia preserve from one to twenty acres of Cabbages thus:—Commencing on one side of a field—if but few heads have been already cut out—the third row is all pulled by the roots, and laid in the adjoining rows; then, with a two-horse plough, run a furrow where the Cabbages stood, returning in the same. If it is desired to keep Cabbages until spring, it should be about 6 inches deep. Then, while men on each side pull the Cabbages from the two adjoining rows and place them and those before pulled—with the roots up—close to this furrow, a man stands astride it, and takes them by the stalks and sets them in the furrow (by drawing them up it a short distance, from front to rear, the leaves will be drawn under the head). When these rows have been thus gone over, the next five—more or less, according to the capacity of the furrows to hold them—are similarly handled. When a number of such furrows have been filled, one strong horse is hitched to the plough and a furrow thrown up on each side of the Cabbages thus set; a ridge is thus made over the heads that will throw off the rain.

**Sowing Cucumber Seeds.**—One hint alone which I got from Mr. David Thomson's "Fruit Culture under Glass," repaid me for the cost of the book. Mr. Thomson soaks his Cucumber seeds in water for twelve hours before sowing them. As many persons know, I make a speciality of growing Long Gun Cucumber seed, and it, like many high-bred Cucumbers, often produces very light seeds. I know this might be remedied by crossing with another sort, but then the produce would be no more "Long Gun." So careful have I been for many years to prevent crossing, that I have not allowed any other kind to flower in my garden whilst growing seeds of this variety. In sowing early in the season I have often been vexed to find a good proportion of the seeds come up very weakly, or refuse to grow. Immediately on reading the above-mentioned paragraph, I soaked some rather light seed all night, and had it sown the next morning, and nearly every seed came up at once, almost as quickly as Mustard and Cress would have done. Talking over the matter with a good gardener this morning, he said that he had practised the plan of soaking his seeds for some time, and had proved that a seed so light even as to float on the water would, after soaking for a time, sink, and when sown would grow and produce a healthy plant. Probably this may be known to many, but it was new to me.—J. R. PEARSON, *Childwell*.

### NOTES AND QUESTIONS ON THE KITCHEN GARDEN.

**Manuring.**—In my paragraph on this subject in last week's GARDEN (p. 118), instead of 9 square feet, read 4 feet square, which really means 81 square feet. Thus to every 81 square feet of land, my neighbour applied a barrowful of manure, whereas I applied the same quantity to little over 16 square feet.—A SURREY MARKET GARDENER.

**To Protect Peas from Mice and Birds.**—M. Gloede, in the *Révue Horticole*, recommends the following as a most effectual protection for newly-sown Peas:—"Twenty-four hours before sowing I steep my Peas in water. I then powder them over with red-lead, rolling them about in it so that it may adhere to and cover the entire surface. After this I plant them in the ordinary way, and for ten years, during which I have followed this plan, my Peas have never been attacked by mice. Birds will occasionally scratch up a few, but they never eat them, and any that happen to be thus picked up are left on the ground untouched."

**Snow's Winter White Broccoli.**—Like many others I have seldom been able to obtain this valuable Broccoli true to name, I therefore now grow in its stead, Sutton's Superb Early White, with the following results: The first sowing, made on March the 1st, came into use on December the 15th; the second sowing, made on April the 3rd, came in on January the 14th; and the third sowing, made on April 29th, is now (February 20th) coming into use, white and solid, the heads being about as large as an ordinary breakfast cup, a size which I have always found to be most esteemed by good cooks. I wish it to be understood, however, that this Broccoli does not resemble the true Snow's Broccoli in growth. Neighbours of mine who are growing sorts named Snow's have not yet cut one head, nor have they any signs of any.—THOMAS DAVIES, *Par Hill, Reading*.

## THE LIBRARY.

### HESIOD AND THEOGNIS.\*

THIS well-written little book is one of the series of "Ancient Classics for English Readers," which are now being published by Messrs. Blackwood in handy and neatly got-up quarterly volumes at 2s. 6d. each. It contains a masterly summary of the lives and writings of these two ancient poets, of the former of whom (the possible contemporary of Homer, and the earliest writer on agricultural subjects) the author well observes in his preface that "nine out of twelve students finish their classical course with but the vaguest acquaintance with his remains. Such, therefore, ought to be as thankful as the unlearned for an idea of what he actually or probably wrote." Commencing with a succinct but graphic account of the life of Hesiod, which "has been compiled from ancient and modern biographies, with a constant eye to the internal evidence of his extant poetry," Mr. Davies presents us, in the four succeeding chapters, with a comprehensive analysis of "The Works and Days," "The Proverbial Philosophy," "The Theogony," and "The Shield of Hercules," abundantly illustrated by quotations from these works, as rendered in the excellent English versions of Elton and Chapman, and the equally spirited occasional translations of the editor himself. The sixth chapter closes the first part of the book with an interesting notice of "The Imitators of Hesiod," in ancient and modern times. The remainder of the volume is devoted to three chapters on Theognis, an account of whose life and works will be an acceptable novelty to non-classical readers, few of whom, we believe, know this poet even by name. We regret that want of space prevents us from giving a few extracts; but we most heartily recommend Mr. Davies's work to all who can appreciate the results of ripe and able scholarship expressed in the language of a finished style, a correct judgment, and a refined taste.

\* "Hesiod and Theognis." By the Rev. James Davies, M.A., late Scholar of Lincoln College, Oxford, Translator of "Fabrius." William Blackwood and Sons, Edinburgh and London, 1873.

## THE GARDEN IN THE HOUSE.

## DIEFFENBACHIA PICTA.

ALL the Dieffenbachias are extremely handsome plants when young and well grown, but as they get old their stems become long and naked. The ease with which they may be propagated, however, renders this defect the less to be regretted; for, immediately they get "leggy," they should be decapitated, removing along with the crown an inch of bare stem. Insert this in a brisk bottom heat in a close, moist, and well-shaded frame within the stove, or under a hand-light in the same situation, and a new stocky plant, well furnished with foliage to the root, will be the result. Nor does this decapitation finish the task of the stem, for if it be kept in the pot it will soon emit shoots, those at the top being the most prominent, all of which can be taken off and treated as cuttings. By cutting the stem into as many pieces as there are joints, and laying them in sand kept moderately moist and in a stove temperature, they soon form plants. As window plants in summer, Dieffenbachias are very useful, their beautifully-variegated leaves, together with their tropical appearance, rendering them great favorites. For house decoration it is not, however, advisable to have them in large pots, six-inches being sufficient.

Dieffenbachia picta.

especially in cases in which they are placed within vases. When associated with Ferns, *Alocasia metallica*, and a few other plants, within a Wardian case furnished with suitable means of ventilation and good drainage, and situated in a warm room in a shady window, they form beautiful and lasting objects. A compost of equal parts turfy loam and fibrous peat, together with some well-decomposed manure and a little sand, suits this Dieffenbachia perfectly, but a little extra loam should be mixed with the soil for potting such plants if it is as are destined for house decoration. P.

**Plant Contrivances for Rooms.**—A pretty and artistic arrangement for a winter greenery is to obtain from the roadside one of those peculiar excrescences which are found growing upon the stumps of decayed trees, resembling brown rosettes of several shades, and very curiously striped. One of these, placed in the centre of a large shallow dish with earth around it, will be quite ornamental when covered with such things as Ivy, *Lycopodium*, *Tradescantia*, and the lovely blue *Lobelia*. Especially will it flourish if a shade is placed over the whole. Common Ivy may be quickly rooted and made to grow vigorously if planted in a box or dish of earth with a glass over it, looking green and refreshing all winter, and in the spring it can be transplanted into the garden outside, where it will cling to the brick wall of your house, and climb much faster in consequence of this early start under glass. Or the long sprays of Ivy may be gathered, and the ends put into water in bottles or deep vases, and will there strike root as vigorously as if in soil.

WORK FOR THE WEEK.  
PRIVATE GARDENS.

**Flower Garden.**—Evergreens must be cleared of snow, of which we have again had a heavy fall; if allowed to rest on the branches, it is apt to break them. As soon as the snow has disappeared, finish all operations in the way of ground-work that may be in hand. Sweep and roll lawns and walks, repairing the margins of the latter where necessary. Indiciously prune evergreen shrubs, such as Aucubas, Hollies, Bays, Box, Yews, Portugal and common Laurels, Junipers, Thujas, Cypresses, Ivies, &c., which may be outgrowing the spaces allotted to them, keeping symmetry and gracefulness of form as much as possible in view. The knife is better than shears for such an operation, the latter being apt to mutilate the leaves. Roses should now be pruned, the plants having in many cases already made shoots nearly an inch in length. As soon as the snow has left us, herbaceous plants should be trimmed, and the crowns should be lifted, divided, and replanted in deeply-worked, well-manured soil; some of the more tender kinds may, however, be left a little longer before being disturbed. Lilies of various sorts and other bulbous plants, as a rule, thrive best and flower most satisfactorily when left for some years undisturbed. The stock of bedding plants may be increased as expeditiously as possible from cuttings, roots, and seeds.

**Conservatories.**—These are now quite gay with early blooming bulbous and other plants. Pots containing three or four Tulips, bordered with Club-moss, and set off in the centre with such Ferns as *Pteris serrulata*, have a beautiful effect, and the same arrangement may with advantage be carried out in the case of Hyacinths. Forced shrubs are now particularly attractive, and should be mixed harmoniously with such plants as are not in flower; amongst them are Lilacs white and purple, Weigelas, Roses, Prunuses, Thorns white and scarlet, Spiraeas, Deutzias, Acacias, &c. Cinerarias, Cyclamens, Zonal Pelargoniums, Chinese Primulas, Epacrises, Heaths, and Fuchsias, are also now in great beauty. Plants in general are making fresh growth and consequently require more water. Prune and tie all that require such attention. Any that are in a backward condition in borders should be moved and have others put in their places. In planting from pots loosen the ball of soil and spread out the roots, for although this may occasion a little check for a time, the plants thrive better afterwards. All hard-wooded plants requiring repotting should be attended to at once, and afterwards kept for a time in the closest part of the conservatory. They should not be watered for some days after being potted, but the atmosphere should if possible be somewhat damp. Climbers of various sorts should be thinned and tied, taking care in thinning to provide for a free display of flowers rather than a gross production of wood.

**Stoves.**—Gradually increase atmospheric humidity and temperature in these structures, though very sparingly, and apply water rather more liberally to the roots of the plants. Almost all stove plants will now require repotting or top-dressing, and insects, if any, must be destroyed; for should they be spared till next month they will reward such kindness by committing unlimited mischief. Plants of all kinds should, therefore, be thoroughly cleaned before they are repotted. In the evening place over some boiler "at work," or introduce into some warm house or pit, some soil, mixed and ready for potting purposes, for no stove plant should be shifted into cold soil. Shift Palms, using for the purpose a compost consisting of fibrous peat two parts, turfy loam one part, and some sand and finely broken crocks, an open compost and plenty of water being requisite for such plants. Shake out plants of Impatiens and repot them in a mixture of loam, leaf-mould, well-decomposed manure, and some silver sand. Give Gardenias a compost of loam and peat in equal proportions, mixed with sand; the same compost, with a little more loam mixed with it, will also suit Brownias. *Dalechampsias* should have leaf, loam, and peat, in about equal proportions; *Stephanotis* fibrous loam, peat, and some well-decayed manure; *Sanchezias* and *Rondeletias* peat, loam, a little leaf-mould, and sand; and *Lagerstromias* peat and loam. Indeed most hard-wooded plants grow freely in good peat and loam, with some silver sand added, and but few of them will object to the addition of a little leaf-mould. Gross-growing and soft-wooded plants, however, such as *Musas*, *Crimmuses*, *Eranthemums*, *Torenias*, *Pnyas*, *Pentas carnea*, *Gesneras*, *Lasiandras*, *Coccyphselmus*, *Curemmas*, &c., are very fond of some thoroughly decayed manure mixed in the soil in which they are potted; leaf-mould, Mushroom dung, spent hot-bed manure, &c., may be so used.

**Indoor Fruit and Forcing Department.**—Increase the day and night temperature of Pine-pits, in accordance with the weather, and give a little extra moisture to the roots, especially those of plants swelling fruit, but such as have nearly finished swelling should be kept moderately dry. Shift into fruiting pots all plants requiring that attention, and take off and pot suckers as they

become ready. Do not starve young growing plants, for if once checked they are almost sure to produce small and premature fruit. Syringe with tepid water the surface of the beds and about the necks of growing plants, especially on fine days. As regards Vines, thin and stop the shoots, thin the berries, and keep up a steady, moist temperature. Thin young Peaches where too thick, but do not make the final thinning until after the stoning period is over, and until that time maintain a steady and moderately low temperature. Regulate and thin the young shoots, and syringe morning and afternoon with tepid water on fine days, and once every day, regardless of the weather. If a little top air can be left on at night, and artificial heat given to maintain the requisite temperature, it will be of material importance to the crop. For Cherries a temperature of 50° or 55° will be sufficient until the fruit has stoned; afterwards the heat may be increased 10° by sunheat, and when the fruit is colouring a night temperature of 60° and a day one of 75° or 80°, with sunheat, will not be too much for them. An airy house and a position near the glass is of the utmost importance in Cherry forcing, and a high temperature either by night or day before the fruit has stoned is ruinous. Give manure-water occasionally to Fig trees swelling their fruit, and syringe them freely until they begin to ripen. Pot Figs are commonly used for the earliest crop, and where houses are not specially devoted to their culture they may be successfully ripened in the Pine-stove or early vinery. Stop the young shoots at the third or fourth joint, and remove all root suckers unless a few are wanted next winter for fresh plants. The earliest Strawberries will now be ripe or ripening, therefore they are best kept moderately dry and airy. Introduce plants of them for succession into Peach-houses or vinery shelves, or into houses built purposely for them. For Cucumbers keep up a bottom heat of 75°, and an atmospheric one a few degrees lower; but in the event of bright weather, an extra 5° would be rather beneficial to them than otherwise. If the heat from fermenting material be waning, apply fresh linings or mix fresh dung with the old fermenting material. Sow a good successional crop of Cucumbers and Melons. Kidney Beans should be sown in succession fortnightly, or according to the demand: a Cucumber-house, Pine-stove, or early vinery suits this crop perfectly, and the plants must be freely syringed, to keep down red spider. Sow a few Tomatoes at once in a moderate hot-bed. Dust some sulphur over the foliage of Potatoes grown in frames, to keep down fungi. Apply water between the drills, but keep the necks of the plants dry. Rhubarb will soon be obtained abundantly from the open air, *i. e.*, if a forkful or two of litter be placed over the crowns; but a few roots for succession may still be taken into the Mushroom-house. Keep up a succession of forced Asparagus, either by placing roots in moderately-heated frames or by filling trenches between the beds with fermenting material. Start a few more Sea-kale roots. A temperature of 60° and a humid atmosphere should be maintained in the Mushroom-house. Protect Lettuces in frames from snow and wet, and plant some out as convenient and weather may permit; sow some seeds in a frame for succession. Sow a few Cap-sicums in boxes, and pot them off singly, or prick them off when they are fit to handle. Sow some Celery seeds in a gentle heat. Sow some New Zealand Spinach in a brisk temperature, for summer and early autumn use. Thin Carrots in frames; keep them dry and shelter them from snow or rain; but expose them freely in favourable weather. Sow some Turnips, Radishes, and Onions in very gently heated frames, to precede those sown out of doors.

#### NURSERIES.

**Indoor Department.**—The repotting and starting into growth of young plants will now occupy attention. In the case of Marantas, Ferns, and many other plants of which stock is scarce, the crowns may be divided, potted singly, and subjected to a brisk, moist temperature. Propagation of all kinds of plants must now be pursued with activity. Continue to sow Palm seeds as directed last week. Musa seeds treated in this way soon vegetate, and require careful attention and frequent potting; over-potting, however, must be avoided. Yuccas may be raised from seed, and the young plants should be pricked off soon after they have germinated. Cuttings and suckers of Yuccas ought also now to be used for purposes of propagation, and the long stems, if treated like those of Dracenas or Dieffenbachias, may also be employed for the same purpose. Sow seeds of *Acacia lophantha*, *Sensitive plants*, *Wigandias*, *Ricinus*, *Solanums*, *Mesembryanthemums*, *Echeverias*, and other plants required for outdoor summer decoration. Sown in heat now, and potted onwards as they require it, they form nice plants by the middle of May. Propagate, by means of cuttings, nearly all kinds of stove and greenhouse plants. New Zealand plants, as a rule, root best when short young shoots are selected for the purpose. Proceed with the grafting of Azaleas, Camellias, Rhododendrons, Roses, greenhouse hard-wooded plants, Clematises, Cacti, and Conifers. If bulbs of any particular plant

are scarce, make two cross cuts on the base of the bulb and hang it up in a moist pit or house, with a string, so that the base shall be uppermost; young bulbils will soon appear on the edges of the incisions. Cacti may be scored on the top for a similar purpose, but in their case no necessity exists for anything but ordinary treatment. Increase the stock of bedding plants by means of seeds, cuttings of branches, stems or roots, layers and suckers. Start Dahlias into growth, and take off the young shoots when a little over an inch in length; treat them like cuttings, and afterwards pot them singly in 60-sized pots. Cannas should be divided into as many pieces as there are crowns, and each potted singly. Good-rooted plants should be removed to frames kept rather close and moderately heated, if practicable, so as to make room for younger stock.

**Outdoor Department.**—Plants to be kept another year or more should now be transplanted in lines sufficiently far apart to give space enough for a good year's growth. Young Oaks, Chestnuts, Beeches, Elms, Limes, &c., that have produced branches near their base, should have such pruned off, so as to encourage thrifty growth. Deciduous trees should now be layered. Those layered last year being now transplanted, room will be found for fresh layers, which, like their predecessors, will be ready for transplantation next October or November. Bend down the shoots, fix them in the ground with pegs, and cut off their tops six inches or so above the ground. Get all stocks for next year's grafting or budding or transplanted permanently at once in ground well manured and trenched, in lines two feet apart. Cut over stocks for grafting this spring about a foot above the ground, and burn all rubbish and prunings lying about the nurseries.

#### MARKET GARDENS.

With draw-hoes stir the soil amongst growing crops, more especially Cabbages. Ground that has just been cleared of Celery should be levelled, manured, deeply dug, and smoothed down with a wooden rake or short-tined harrow, and marked off in lines about 20 inches or 2 feet apart. These lines should be marked both lengthwise and crosswise, and Cauliflowers should be planted in the angles. Between the rows of Cauliflowers plant a line of Lettuces, and also a plant of the latter between every one of the former. If the field be large, the most convenient plan of operation is to have some men carting manure, one or two spreading it, others digging, two lining it off, the remainder planting, and a few workwomen pulling plants and carrying them to the planters. To Cauliflowers thus planted in an open field, some earth should be drawn with a hoe in such a way as to protect their necks a little from cold. Where the soil has been trenched in 2-foot wide ridges, having a south or south-west aspect, the front of these ridges, if not already perpendicular, may be made so by a touch of the dibber or tramp of the foot, or, if necessary, with a spade; and Cauliflower plants should be inserted 2 feet apart at the base of the ridges, a situation in which they will find good protection until they begin to grow. On fine days, such as we had last Saturday, handlights should be wholly removed from the early planted-out Cauliflowers, but replaced at night; on less favourable days, but not frosty, they may be tilted up by means of a flower-pot or half brick. All plants buttoning or likely to be otherwise useless should be removed at once. Those in frames may be planted out, taking the most advanced plants first. The strongest Lettuces, and especially those amongst Carrots, should be selected first for transplanting, and great care should be taken to preserve them from damp, snow, or rain whilst in the frames. If not already done, some more Cos Lettuces should be sown in frames, the sashes from which should be entirely removed during the day, after they germinate, unless it is wet, and then they should be tilted up. Throw out some pits 18 inches deep and 6 feet wide, with 2 or 3 feet spaces between them, and fill them with fermenting manure. Over the manure put 9 inches of soil, level the surface and smooth it with the back of a spade or roller, and sow thereon some white Dutch Turnips. Over the seed sift some soil from the spaces between the beds and then cover with litter in the way in which Radishes are covered. By this means an early crop is soon secured. Celery seed should be sown at once in a similar way, for, raised under such circumstances, the plants are hardier and not so liable to "bolt" as when treated more tenderly. Some more Radishes should be sown on the last lifted Rhubarb plantation, and covered with litter. Rhubarb is now growing fast, some in sheltered places having formed leafstalks 6 inches long; the sooner, therefore, the crowns are covered the better—not with the view of forcing them, but merely for the purpose of protecting them a little from cold, and of inducing the stalks to come tender, crisp, and clean; the market returns, indeed, soon indicate the importance of thus covering the crowns. When plantations of Rhubarb are extensive, it is impossible to cover all the crowns in this way at one time, especially where there are other uses to which the litter should be put, such as covering Radish beds, Mushroom ridges, &c.; but all that can be spared should be thus applied.

## NOTES OF THE WEEK.

— THE Council of the Royal Botanic Society have agreed upon estimates for building a new and extensive range of houses for preserving the rapidly increasing collection of economic plants possessed by the society.

— CONTINENTAL journals announce that it is intended to hold a great Horticultural Exhibition at Florence in 1874, of which Professor Parlatore will be the director or president. In connection with this event, a Congress of Botanists is also spoken of as likely to meet there.

— THERE is at present in flower in the hothouse of the Muséum at Paris, a very fine specimen of *Bambusa arundinacea*, the great Indian Bamboo. This, we believe, is the first instance on record of the flowering of this species in Europe.

— A SINGLE plant of the handsome-leaved climber, *Cissus discolor*, now growing in the gardens of M. Linden, at Gand, during the past year produced new shoots, the total aggregate of the length of which amounted to upwards of 1,625 feet! M. E. André informs us that the plant was grown in a mixture of coal-ashes and spent tan.

— THE Council of the Royal Society are about to nominate Dr. Hooker, director of the Royal Gardens, Kew, as president of the society, in succession to Sir George Airy, who, as will be remembered, has announced his intention of retiring from the chair at the society's anniversary in November next.

— THE value of Potatoes imported last month was £282,303, and £15,987 in January last year; while in the same month of 1871 the declared value was only £222.

— IN a Lemon plantation at Palermo last year there was a serious deficiency in the crop, in consequence of many of the trees having produced double flowers.

— IT would appear that in America fruit nomenclature is occasionally at fault, if we may judge from the following from the *Albany Cultivator*:—"Please inform me," says a correspondent of that paper, "where to get the Baker Apple tree, so as not to be humbugged."

— ABOUT fifteen years ago, M. E. Carrière, the able pomologist of the Jardin des Plantes at Paris, made an experiment in grafting two varieties of Pear (the *Beurré de Malines* and the *Fondante des Bois*) on the Doucin Apple stock. We now learn that the Pears thus grafted have not only grown well but have also borne crops of excellent fruit.

— THE Rev. H. N. Ellacombe, Bitton Vicarage, Gloucestershire, writes to us as follows concerning the pretty little *Iris stylosa* and *Anemone blanda*:—"Of all hardy spring flowers I think there is none to surpass *Iris stylosa*, now in flower in my garden; yet it is very seldom grown. It is perfectly hardy, increases rapidly, and the flowers are much more lasting than those of most of the family. Another beautiful spring flower very little grown is *Anemone blanda*. It is closely allied to *A. apennina*; but the colour is much darker, and it comes into flower some weeks earlier."

— AT a private meeting of the members of the Fruit, Floral, and Scientific Committees belonging to the Royal Horticultural Society, held at the Charing Cross Hotel last Monday, Dr. Masters in the chair, it was resolved to form a Horticultural Defence Committee, consisting of three representatives from each committee, as follows:—Dr. Hogg, Mr. H. J. Veitch, and Mr. G. F. Wilson, F.R.S. (Fruit Committee); Mr. J. Fraser, Mr. B. S. Williams, and Mr. T. Baines (Floral Committee); Mr. R. Fortune, Mr. T. Moore, and Dr. Masters (Scientific Committee); hon. sec., Mr. H. J. Veitch. This committee is not pledged to any particular course, but will watch the course of events, and take such steps as may be desirable, having power to summon a general meeting when occasion demands.

— AT a sale of Orchids, Tree Ferns, Camellias, and Lilies which took place at Stevens's on the 20th ult., the following prices, amongst others, were realised:—Good plants of *Odontoglossum vexillarium* fetched £9 9s., £6 10s., £5 5s., £4 10s., and £3 12s. 6d. respectively; a good specimen in flower of *O. Andersonianum* £6 15s.; flowering plants of *O. Alexandre* £5 15s. and £2 10s.; a flowering plant of *O. gloriosum* £2; and a good one of *Lycaste Skinneri*, also in flower, £2 8s. Plants of *Dicksonia antarctica*, with stems varying from 6 to 7 feet in height, fetched from £4 10s. to £6 10s. respectively; *Cyathea dealbata*, with trunks from 2 feet 6 inches to 7 feet 6 inches in height, realised from £2 5s. to £3 10s. A specimen of *Camellia Tentonia alba*, 6 feet high and 5 feet through, fetched £10 10s.; another of *C. Wilderi*, 4 feet by 3 feet, £6; one of *C. Lavinia Maggi rosea*, 4 feet by 3 feet, £3 3s.; and

others from three guineas downwards. Lots consisting of fifty bulbs of *Lilium auratum* varied in price from £2 2s. to £2 10s. Altogether the proceeds of the day's sale amounted to nearly £400.

— POTATOES, it is said, are now offered in France at 60 francs (£2 10s.) per ton, being less than half the price paid in London.

— THE Manchester International Horticultural Show promises to be the great event of the year. The Queen, we hear, has become a patron, and has subscribed £25 towards the undertaking.

— THE well-known seed and herb business, conducted for the greater part of a century in Covent Garden by Messrs. Butler and McCulloch, will, we understand, in future be carried on by Messrs. Sidney G. Hart, Frederick McCulloch, and Archibald Macdonald.

— FOR the last three years there has been a great increase in the Orange and Lemon trade. The value as declared imported in 1870 was £648,056; in 1871, £1,050,115; and last year as much as £1,154,417.

— DR. BREWER, we understand, is engaged in the preparation of a Flora of California, which is in such a state of forwardness as to be probably ready for the press by the end of the year. Professor Gray and Mr. Watson are, it is stated, rendering assistance in the matter, so as to bring the work to an early completion.

— M. E. BENARY, a horticulturist at Erfurt, announces a new Pansy, which has large flowers of a splendid ultra-marine blue, with a well formed eye of very deep violet-purple. They are also of good substance, have strong stalks, and stand well above the leaves. M. Benary has named it "*Viola tricolor*, var. *maxima* Emperor William," and states that the variety reproduces itself with certainty from seed.

— "We claim the honour," says the *Mobile Register*, "of having started a new interest in Japan Peas, and we are proud of it, for the Japan Pea is undoubtedly one of the best things for our climate. It is easily raised, will grow on almost any soil, and yields enormously. As food for man we think it has no equal in the Pea or Bean way." What is this Japan Pea?

— A NEW JERSEY Cranberry grower, with other parties, has purchased 3,000 acres marsh land in Wisconsin, for the purpose of growing the Cranberry. Wisconsin is becoming famous for her Hop yards and Cranberry fields. But a few years since these marsh lands, now so eagerly sought, were regarded of little or no value or consequence beyond "what they might have possessed to help to hold the world together."

— THE Belgian peasantry employ the following singular method of keeping red Cabbages through the winter:—Towards the end of autumn they select the best headed plants, pull them up, strip off the loose outer leaves, and then lay them in trenches, with the heads of the plants downwards, the soil being well pressed in around each head. An outer trench, a foot deep, is dug around the bed for the purpose of drainage. Cabbages thus treated are said to keep much longer and better than they do if allowed to grow on in the usual way, and especially so if they are stored in this manner in ground with a northern aspect.

— THE *Delaware Tribune* states that the total amount of the last Peach crop in that State was as follows:—Shipped by rail to Northern cities, 1,970,400 baskets; by water to Philadelphia, 759,568; by water to Baltimore, 677,206; consumed by canners and at Wilmington, 83,282—total, 3,491,050 baskets. In addition, it estimates the number eaten on peach farms, distilled into brandy, and shipped to peninsular towns other than Wilmington, as sufficient to make the grand total of 3,600,000 baskets. The average value it puts at 40 cents per basket, so that the crop on this estimate was worth 1,440,000 dollars (or £300,000) to the Peninsula.

— THE twin peaks, known as Torrey's and Gray's peaks, the highest of the Rocky Mountains, as far as known (rising considerably over 11,000 feet), were last summer visited by their discoverer, Dr. C. C. Parry (who first ascended and named them in 1862), and by the botanists whose names he attached to them. The occasion was made one of considerable ceremony on the part of the citizens of Georgetown, who were well aware of the scientific reputation of these gentlemen.

— A FLORA of Perthshire is in preparation, and will be published as soon as the list of subscribers is complete. The contents will include a general introduction—the range of each plant throughout the county (illustrated by a map showing the natural divisions of Perthshire)—the vertical range of plants ascending above 1,000 feet—the distribution in relation to the geological formations—a full list of localities for the rarer or more local species—the economic uses that native plants are still employed for in Perthshire, &c. Volume 1. will include the flowering plants (both native and naturalised) and Ferns. Botanists who can assist with information are requested to kindly communicate at once with Dr. Buchanan White, Eastferry, Dunkeld.

## THE ROYAL HORTICULTURAL SOCIETY.

THE beginning of the end has set in, and what that end must be it is not difficult to foretell. The life of the Royal Horticultural Society has been a most chequered, if not an erratic one, and, with all its misfortunes and mismanagement, there is no denying the fact that within the last half century it has done an immense amount of good; not so much directly, as indirectly through precept, and the example set by its great exhibitions. Forty years ago, and even more recently, its garden at Chiswick was carried on in something like a representative manner; that is, the ground was systematically cropped, and the forcing houses contained fruits of all kinds grown in a fair if not first-rate manner. But gradually the demon of innovation crept in, flowering plants became the rage, the finest collection of Vines in the world was dispersed, and indoor fruits became a secondary consideration. In saying this much let us not be misunderstood, for the truth is, if the Horticultural Society claims the gratitude of the world for anything it is for the very important service it has done in the introduction, selection, and classification of the hardy fruits of all countries. In connection with that service the name of the late Mr. Robert Thompson should never be forgotten, for most unassumingly he produced, in the form of the Royal Horticultural Society's catalogue of fruits, a work which is still of the greatest value to gardeners. Those who can go back to the Sabine "break up" will recollect nothing like that event, except the occurrences of these last three weeks. Then the blame was thrown upon one back, but in justice to a much maligned man it may be still asked would the society have attained the position it did if the extravagances with which Mr. Sabine was charged had not occurred? True, he brought the society into pecuniary difficulties, but he was not a defaulter; what he expended was disbursed for the good of the corporation, and has been repaid forty-fold. It is worthy of remark, too, that the difficulties of those days and the present crisis originate in precisely opposite causes. The removal of the garden from Kensington to Chiswick, "because of the smoke," when Knightsbridge, Kensington, Chelsea, and Brompton were villages surrounded by thousands of acres of open fields, was the origin of Sabine's difficulties. And something like half a century afterwards when the fields alluded to had been absorbed by bricks and mortar, and the smoke nuisance had increased ten thousand-fold, the taking the garden a mile nearer town may be said to be the origin of the difficulty which to-day has caused such wide-spread consternation among horticulturists, and which once more threatens to sap the foundation of the association.

But let it do so. The removal to South Kensington was in obedience to the edict of the time. The society was well nigh insolvent, its Regent-street property and magnificent library had been dispersed, Chiswick was dismantled and a comparative waste, and, as drowning men catch at straws, when the Royal Commissioners threw out the rope, the society clutched it with the desperation of insolvents who saw a prospect of tiding over the then difficulties, but now find it a rope of sand. The garden, beyond its position, never possessed one single element of success for a grand horticultural establishment. The languishing state of shrubs in the immediate neighbourhood ought to have demonstrated that fact, and neither soil, nor washing, nor care could make plants grow, whose lungs were sealed up by means of smoke and dirt. As a representative garden, except as representing what should not be done, nothing could be more complete than the failure of South Kensington; for, shorn of the little gaiety in the way of pot-plants which it draws periodically from Chiswick, there is scarcely an evergreen plant in the place which does not say, "I am sick, take me away." Therefore, as respects gardening, no one need shed a tear at the *finale*, should it come; and as for the tea-garden aspect of the matter of what best suits the Commissioners and the residents of the neighbourhood, let them take the garden and convert it into croquet grounds, or apply it to any other purpose as they may think fit—all gardeners can do without it. We, therefore, so far as the real interest of our calling is concerned, look upon the gathering storm with comparative indifference, and shall not be sorry to see the "Augean stable" cleansed of its present impurities. The Society, rehabilitated upon a better, broader, and more lasting foundation, under the auspices of true gardeners, may, like a good ship, float into calm water, and though with a smaller crew, do more in seven years for the real objects for which the Society was established than South Kensington will do in seven centuries, that is, supposing it to exist for that length of time.

No doubt an attempt will be made to patch up the present difficulties, but it is hoped that gardeners will recollect that the opportunity for reforming the affairs of the Society for which they have been looking has now come, and if they do not use it the fault will be their own.

## FERTILISATION OF FLOWERS BY FLIES.

We are often attracted in autumn by the sight of a swarm of flies—indeed, I may say of bees and butterflies also—busily engaged on a clump of Michaelmas Daisies in full blossom. They rise almost in a cloud as we approach, and disappear, of course to visit some other floriferous clump within easy distance. It is just possible that this phenomenon may attract the notice of the gardener, and that he may regard it as a nuisance that ought to be done away with, and he may send to the nearest chemist for "some stuff" which is to effect a cure. Very rarely indeed will some Darwin stop in passing the clump of flowers to inquire of himself and of the insects what they are doing; however, this inquiry does now and then take place, and will always reward the inquirer with a fund of instruction. Eliminating the bees and the butterflies, let us fix our attention on some most familiar, most abundant, and most ubiquitous insects, commonly known as drone flies, and known by entomologists as *Eristalis*; there are many species, but three of these are so abundant that you literally see them on every flower: these I will call *Tenax*, *Pertinax*, and *Sequax*—all these names implying the pertinacity with which they return to their feast, however frequently they may be driven away. All of them are greedy devourers of pollen, and all of them devour it in the same manner; they thrust their proboscis among the florets, separate the two spreading valves with which its extremity is furnished, grasp a cluster of pollen granules, detach them from the flower, and swallow them. The operation of detaching the pollen granules is not performed without some skill and exercise of ingenuity, for in many flowers the granules are united together by slender tenacious threads, which must be broken before the granules can be swallowed. This swallowing of the pollen is very obvious to the patient observer; the granules, a few at a time, ascend the leathery proboscis and thence descend into the stomach, which becomes gorged with them, and from which they may be extracted, after the insect is killed, in a perfectly unaltered state. The yellow pollen granules frequently impart their colour to the abdomen, more especially to its sides and under surface. After the fly has swallowed a granule or mass of granules thus detached, it occupies several seconds in clearing its head from the granules, threads, and other impurities which still adhere to it—a process performed by its first pair of legs in a manner that strongly reminds one of a cat washing its face with its fore paws. I cannot take upon myself to assert that the three species of *Eristalis* are entirely destitute of the power usually attributed to them of imbibing the liquid honey of flowers; but I am quite clear that I have never detected them in the act, and I am also firmly convinced that pollen in a solid state will almost invariably and exclusively be found distending their bodies. I ought perhaps to state that the whole of my brief holidays in 1870 and 1872 was spent in studying these interesting flies.

We now approach another branch of the subject, and one on which Mr. Darwin has thrown much light. Recurring to the sight to which I have alluded, of the hosts of insects banqueting on a clump of flowers, it may possibly occur to a superficial observer that flowers have an especial duty to perform as regards the insect world—namely, that of feeding them. This, however, is but half the truth; the insect is as essential to the welfare of the flower as is the flower to the welfare of the insect. The curious genus *Stapelia* is fertilised solely by the larva of a fly, generally the common *Musca vomitoria*. This fly, attracted by the offensive smell of the flower, lays its eggs as far as it can in the tube of the corolla. These eggs hatching, the larva they produce come into contact with pollen granules, which adhere to them, and which they carry to the pistils, and thus fertilise them. A similar office is performed for *Cerapegia* by a small fly in the perfect state, which I have never found in any other situation than deep down in the tube of the corolla of this wax-like flower. The most interesting fact, however, remains to be told. Hermaphrodite flowers being provided with both stamens and pistils, pollen and ovary, one would suppose them amply furnished with the powers of reproduction, yet it has been abundantly shown that flowers fertilised by themselves do not produce such vigorous and healthy seeds and off-spring as those fertilised by another flower of the same species; therefore the three species of *Eristalis* I have named—and I have given more particular attention to *E. pertinax*—when they have gorged themselves with the pollen of one floriferous clump, and have roved among flowers until the pollen granules adhere to every part of their bodies, and have then flown away, or been driven away, to another distant clump of the same species, convey a new fertilising element to these distant clumps, and insure the production of more vigorous descendants, provided the seed is allowed to attain maturity. Hence the advantage of renovating by change; hence the disadvantage of breeding in and in; the nearer the degree of consanguinity, the less prospect is there of healthy and vigorous offspring.—*Edward Newman, in Field.*

## HORTICULTURE AT THE INTERNATIONAL EXHIBITION AT VIENNA IN 1873.

From the following details which have been published with respect to this exhibition, it appears that preparations are being made for conducting it on a scale of considerable magnitude. The principal building will be 975 feet in length, and 650 feet wide. It will be erected in the Prater (the Bois de Boulogne of Vienna) and close to that part of the side of the Danube which has been lately embanked and laid out in an ornamental manner. The chief gallery, which runs through the entire length of the building, will have wide transepts on each side, arranged in such a manner as not to obstruct the view of the whole interior. Between these transepts and the great nave are the courts or gardens, and one or more of these transepts, with the corresponding garden and the part of the nave adjoining, will be devoted to each country. A vast rotundo or cupola rises from the centre of the structure, which will be the largest of the kind that has ever been erected, being 325 feet in diameter and 250 high. It will be made of iron after the design of Mr. Scott Russell. The principal gallery, which is 81 feet wide, will have its transepts 89 feet wide and 260 feet long. The covered part of the exhibition will occupy a space of over 25 acres. On the east of the rotundo of the Prater, the exhibition of fine arts will occupy a space of nearly 2 acres. From the principal building will extend covered galleries leading to an immense conservatory, and some smaller structures appropriated to horticulture and to aquariums. Machinery will be located in a separate gallery 2,925 feet long and 88 feet wide. The imperial villa and the hall in which the jury will deliberate are to be erected in the gardens, the laying out of which has been entrusted to a distinguished landscape gardener.

The following is the programme of the general conditions relating to the horticultural section of this exhibition:—

1. A Horticultural Exhibition can in general comprise only (A.) Living or dried plants, or parts of such plants. (B.) Practical illustrations of various modes of culture. (C.) Objects of art and industry, in so far as they either contribute to, or are the results of, horticulture.

2. All dried plants which have been grown in gardens, fresh fruit, grapes on their vines (with the exception of those grown in houses) as well as exotic fruits, will not, for reasons of convenience, be submitted to the jury who will decide on horticultural products, but will be referred to the jury of the agricultural section. They will, however, as objects of exhibition, be placed in the horticultural division.

3. Garden tools will be placed in the section for agricultural implements.

4. In order to form an exact estimate of the condition of horticulture in the different countries of Europe, and of their productions during an entire season of growth, it is indispensable to have two exhibitions, of which one, conducted more especially in the open air and representing the various systems of culture in use, will be permanent, while the other will be divided into four temporary exhibitions of short duration, and arranged with reference to the season and its productions.—(A.) The permanent exhibition will be held from the 1st to the 31st of October. (B.) The four temporary ones as follows:—

The first, from the 1st to the 10th of May, inclusive.

The second, from the 15th to the 25th of June, inclusive.

The third, from the 20th to the 30th of August, inclusive.

The fourth, from the 18th to the 23rd of September, inclusive.

5. Consequently each exhibitor may show either at one or more of these exhibitions.

6. Agreeably to the decision of the general directory, exhibitors from the Austro-Hungarian dominions must send in their applications to the provincial commissions of the Exhibition before the 1st July, 1872, in order that they may be submitted to the director-general of the Exhibition before the 1st of August, 1872. Foreign commissions are requested to send in their lists of exhibitors to the director-general before the 1st of January, 1873. In his application the exhibitor is to state whether he intends to show in the permanent or in one of the four temporary exhibitions, and in the latter case, to state which. At the same time he must mention how much space he will require, in a printed form which will be supplied to him.

7. All objects sent for exhibition must be delivered within the grounds of the Exhibition in the place which has been assigned to them, at least three days before the opening of the Exhibition. Those exhibitors who wish to show in the permanent exhibition will be at liberty to place their contributions as they please, and are requested to give timely notice of their intentions in this respect to the general directory.

8. For horticultural objects exhibited in the open air in the park, either at the permanent or the temporary exhibition, a charge for space will be made at the rate of one florin (Austrian money) for the square metre. In the covered part of the exhibition the charge for the same space will be three florins.

9. The director-general will do all he can to obtain from the Austrian railway and other transport companies a reduction of rates for the carriage of objects intended for exhibition. The results of his exertions in this way, as well as any reduction of rates that may be obtained by foreign commissions, will be published by the director-general before the first of July, 1872.

10. The transplanting of plants and the care of them during the exhibition, will be at the expense of the exhibitor or his representative.

The director-general cannot take upon himself any responsibility respecting them.

11. No object can be removed by the exhibitor before the end of the exhibition for which he has applied, without the special permission of the director-general. This permission will be given at once, if the exhibitor engages to replace the objects removed by other suitable ones.

12. Objects shown at any of the four temporary exhibitions must be removed by the exhibitors at the expiration of the time fixed on for the close of the exhibition; otherwise they will be removed and sold at the exhibitors' expense. If the exhibitor does not claim the product of the sale within three months afterwards, he will be considered to have renounced all claim to it.

13. Exhibitors may have themselves represented by agents or by the commission of the country to which they belong, and may give them instructions to remove and sell their property.

14. All objects in this section (with the exception of those which the exhibitors do not wish to have judged) will be submitted to the decision of an international jury. Special regulations on this point will be published later.

15. The prizes will be awarded by the international jury, in conformity with the regulations contained under the fourteenth heading of the general programme.

16. Questions relating to the sending, receiving, and placing of objects, of which no mention is made in this special programme, are disposed of under the third heading of the general regulations.

## COVENT GARDEN MARKET.

FEBRUARY 28TH.

**Flowers.**—Of these there is now a large assortment, prominent amongst which are Chinese Primulas, Cyclamens, Heaths, Tulips, Cinerarias, Hyacinths, small Azaleas, Callas, Cytisuses, and Emurises. There are, moreover, small evergreen Conifers and other plants of that kind. Cut flowers consist of Orchids, Lily of the Valley, Rose-buds, Camellias, Azaleas, Acazia, Rice-ma, Violets, Fuchsias, Pelargoniums, both zonal and show kinds, Anaryllises, Dentzias, and others.

**Fruit.**—Home grown Pines are scarce, but some of them are excellent; a good supply is, however, still furnished from St. Michaels and Sierra Leone. English Grapes are good; they consist chiefly of Barbera's, Lady Downes, and Trebbiano. Strawberries still make their appearance. Pears and Apples are comparatively scarce.

**Prices of Fruits.**—Apples, per half sieve, 3s. to 5s. 6d.; Cobs, per lb., 2s. to 2s. 6d.; Grapes, hothouse, per lb., 6s. to 12s.; Lemons, per 100, 4s. to 8s.; Melons, Spanish, each, 2s. to 3s.; Oranges, per 100, 4s. to 8s.; Pears, per doz., 8s. to 12s.; Pine-Apples, per lb., 6s. to 10s.; Walnuts, per 100, 2s. to 3s.

**Prices of Vegetables.**—Asparagus, per bundle, 8s. to 25s.; Beans, French, per 100, 2s. to 3s.; Beet, Red, per doz., 1s. to 3s.; Broccoli, per bundle, 9d. to 1s. 6d.; Cabbage, per doz., 1s. to 2s. 6d.; Carrots, per bunch, 4d. to 6d.; Cauliflower, per doz., 2s. to 6s.; Celery, per bundle, 1s. 6d. to 2s.; Coleworts, per doz., bunches, 3s. 6d. to 5s.; Cucumbers, each, 2s. to 3s.; Endive, per doz., 1s. to 2s.; Fennel, per bunch, 3d. to 6d.; Garlic, per lb., 4d. to 6d.; Herbs, per bunch, 3d.; Horseradish, per bundle, 3s. to 5s.; Leeks, per bunch, 2d. to 6d.; Lettuces, per score, 1s. to 2s.; Mushrooms, per pottle, 2s.; Mustard and Cress, per punnet, 2d.; Onions, per bushel, 2s. to 5s.; pickling, per quart, 6d. to 9d.; Parsley, per doz. bunches, 3s. to 4s.; Parsnips, per doz., 9d. to 1s.; Potatoes, Kildney, per cwt., 10s. to 15s.; Potatoes, Round, per cwt., 10s. to 15s.; Potatoes, per doz. bunches, 6d. to 1s.; Salsify, do., 1s. to 1s. 6d.; Seakale, per punnet, 1s. 6d. to 2s.; Scorzenera, per bundle, 9d. to 1s.; Spinach, per bushel, 3s. to 4s.; Tomatoes, per doz., 1s. to 3s.; Turnips, per bunch, 3d.

## LONDON FRUIT AND VEGETABLE MEASURES.

These being made either of wicker-work or deal shavings, vary triflingly in size more than measures made of less flexible materials.

**Sea-scale Punnets.**—Eight inches diameter at the top, and seven and a-half inches at the bottom, and two inches deep.

**Radish Punnets.**—Eight inches diameter, and one inch deep, if to hold six hands; or nine inches by one inch for twelve hands.

**Mushroom Punnets.**—Seven inches by two inches.

**Salading Punnets.**—Five inches by two inches.

**Half Sars.**—Contains three and a-half imperial gallons. It averages twelve and a-half inches in diameter, and six inches in depth.

**Sieve.**—Contains seven imperial gallons. Diameter fifteen inches, depth eight inches. A sieve of Currants twenty quarts.

**Bushel Sieve.**—Ten and a-half imperial gallons. Diameter at top seventeen inches and three quarters, at bottom seventeen inches; depth eleven inches and a quarter.

**Bushel Basket.**—Ought, when heaped, to contain an imperial bushel. Diameter at bottom ten inches, at top fourteen inches and a half; depth

seventeen inches. Walnuts, Nut, Apples, and Potatoes are sold by measure. A bushel of the last-named, cleaned weighs 56 lbs., but 4 lbs. additional are allowed if they are not washed. A junk contains two-thirds of a bushel.

**Pottle.**—Is a long tapering basket that holds rather over a pint and a half. A pottle of Strawberries should hold half a gallon, but never holds more than one quart; a pottle of Mushrooms should weigh one pound.

**Hand.**—Applies to a bunch of Radishes, which contains from 12 to 30 or more according to the season.

**Bundle.**—Contains 6 to 20 heads of Broccoli, Celery, Ac.; Seakale 12 to 18 heads; Rhubarb, 20 to 30 stems, according to size; and of Asparagus from 100 to 125.

**Bunch.**—Is applied to herbs, &c., and varies much in size according to the season. A bunch of Turnips is 12 to 25; of Carrots 15 to 40; of greens as many as can be tied together by the roots.

Grapes are put up in 2 lbs. and 4 lbs. punnets; new Potatoes, by the London growers, in 2 lbs. punnets. Apples and Pears are put up in bushels, sieves, or half sieves. A hundred weight of Kentish Filberts is 100 lbs. Weights are always 16 ozs. to the pound.

# THE GARDEN.

“This is an art  
Which does mend nature: change it rather: but  
THE ART ITSELF IS NATURE.”—*Shakespeare.*

## HARDY LADY'S SLIPPERS.

How rarely it is that one has an opportunity of inspecting any of the hardy Lady's Slippers in bloom. The first time we visited Messrs. Backhouse's Herbaceous Plant Nursery at York, we were agreeably surprised to find two species of hardy *Cypripediums* growing vigorously, viz., *C. Calceolus*—our British representative of the genus, and *C. spectabile*, the former being in full flower. A great patch, sheltered by a huge boulder, was luxuriating in an eastern

The Showy Lady's Slipper (*Cypripedium spectabile*).

aspect in a loamy soil, with an admixture of chalk. Here, bathed in the morning sunlight, at least thirty open flowers swayed to and fro in the cool breeze. *C. spectabile* was coming up strongly from a bed of peaty soil, and promised fair to yield a fine display of blossoms. How is that we import hardy Lady's Slippers, and lose them? Simply because we object to nature as a teacher. We gather herbaceous plants in moist, shady valleys, surrounded by fresh sphagnum, and moistened by the rippling brook or trickling mountain stream; and then we wonder why they do not luxuriate with us at home, in our borders or in pots, when subjected to every vicissitude of heat and moisture. It should be one of the first considerations with us to select a nice warm corner for any rare plant we meet with in our travels, and yet they are often planted in the dry, harsh soil of an ordinary border, where irregularity in the supply of water and a scorching sun soon complete their work. We should recommend everyone interested in the culture of hardy *Cypripediums* and other choice moisture and shade-

loving plants to spend a week in exploring the sheltered ravines (in the vernacular "gills") to be found in many parts of Yorkshire and other northern counties. Down these gills a splashing stream, generally as clear as crystal, tumbles over rocks and boulders, or ripples smoothly over polished pebbles, while speckled trout dart here and there from the shallows into the deepening shade of the overhanging fern-clad banks. The lesser tributaries of these hillside streams often spread themselves out, forming miniature bogs and moist patches, on which sphagnum moss grows in profusion. The ground shakes as we proceed, and if one stands for a few seconds the water oozes up from the peat and moss, and forms little lakes around our feet. Would that we had these spongy bogs and cool peat-beds covered with fresh sphagnum in our gardens; then we should not have to lament over the loss of our hardy *Cypripediums*. How they would luxuriate in such positions along with *Sarracenia purpurea*, *Darlingtonia californica*, and many other plants, among which may be named *Fritillarias*, Lilies, and sub-aquatics that at present defy our best endeavours to cultivate them either in pots or in the common type of herbaceous borders.

We now propose to enumerate and describe all the hardy *Cypripediums* at present in cultivation, with remarks on the treatment and positions suitable for each kind.

**CYPRIPEDIUM SPECTABILE.**—The most beautiful of the genus; 15 inches to 2½ feet high. Flowers in summer, one or two (rarely three) on each stem; large, handsome, white, with a much inflated rounded lip, about 1½ inch long, white, and marked with a large blotch of bright rosy-carmine in front. A variety (*C. s. album*) has the lip entirely white. Leaves oval, pointed, pubescent, veined. N. America, from Canada to Carolina, in marshy places. Thrives to perfection in the artificial bog, and does well in moist borders. It should always be planted in deep, moist peat or vegetable soil, in a sheltered, half-shady position.

**CYPRIPEDIUM PUBESCENS.**—A dwarfer species than the last-named, with a pubescent stem, seldom more than 2 feet high. Flowers early in summer, one to three on each stem, scentless, greenish-yellow, more or less spotted with brown, with a pale yellow lip from 1½ to 2 inches long, and flattened at the sides. Leaves broadly-oval, pointed, pubescent. America, in bogs and low woods, from Pennsylvania to Carolina. Does well on dry sunny banks, among loam, stones, and grit.

**CYPRIPEDIUM GUTTATUM.**—A handsome rare kind, seldom seen in gardens. Grows from 6 to 9 inches high. Flowers in summer, solitary, rather small but beautiful, white, heavily blotched or spotted with deep rosy-purple. Leaves two, alternate, oval-elliptical, pointed, downy. Canada, N. Europe (near Moscow), and N. Asia, in dense forests amongst the roots of trees in moist, black vegetable mould. Requires a shady position in leaf-mould, moss, and sand, and should be kept rather dry in winter.

**CYPRIPEDIUM MACRANTHUM.**—This species bears a considerable resemblance to *C. ventricosum*, but has lighter-coloured flowers. It grows about a foot high. Flowers early in June, large, of a uniform purplish rose-colour with deeper-coloured veins. Lip globose, inflated, finely marked with deep purple reticulations. Siberia. This handsome, and at present rare species, may be treated in the same manner as *C. guttatum*.

**CYPRIPEDIUM ACAULE.**—A dwarf species with a naked downy flower-stalk from 8 to 12 inches high, and bearing a green bract at the top. Flowers early in summer, large, solitary, of a greenish colour, with a rosy-purple (rarely white) lip, which is nearly 2 inches long, and has a singular closed fissure down its whole length in front. Leaves two, at the base of the flower-stem, oblong, obtuse, downy. Northern States of North America, in woods and bogs. Requires a shady position in moist peaty soil or leaf-mould.

**CYPRIPEDIUM CALCEOLUS.**—The only British species of *Cypripedium*, and the largest flowered of our native Orchids. Grows from 1 to 1½ foot high. Flowers in summer, solitary (sometimes two), large, of a dark-brown colour, with an inflated clear yellow lip netted with darker veins, and about 1 inch in length. Leaves generally three or four in number, large, ovate, pointed, veined. North Europe, and occasionally found in the northern counties of England, where, however, it is now almost exterminated by unscrupulous plant gatherers. A very

ornamental plant for the rock-garden, where it should be planted in sunny sheltered nooks in calcareous soil, or in narrow fissures of limestone rock well drained, in rich fibrous loam. It prefers an east aspect.

**CYPRIPEDIUM VENTRICOSUM.**—A dwarf species, with an erect, slightly angular stem 1 to 1½ feet high. Flowers early in summer, one or two on each stem, large, of a reddish-purple, with a very large inflated lip of a brilliant purple hue, edged with pure white round the mouth. Leaves three, broadly ovate, acute, thickly clothed on both sides with short hairs. Eastern Siberia. Requires a shady position in peaty loam or leaf-mould.

**CYPRIPEDIUM CANDIDUM.**—A dwarf small-flowered kind, 8 to 15 inches high. Flowers early in summer, solitary, greenish-brown with a white lip about the size of a sparrow's egg, and marked with rose-coloured dots on the inside. Leaves oblong, lance-shaped, acute, slightly pubescent. North America, in bogs from Central and Western New York to Kentucky and Wisconsin. May be grown in the artificial bog, or in moist peaty spots near the rock-garden, but is best suited for a botanical or curious collection.

**CYPRIPEDIUM ARIETINUM.**—The smallest species of *Cyripedium*, with a slender stem 6 to 10 inches high. Flowers in summer, solitary, greenish-brown, with a red and whitish-veined lip half an inch long. Leaves three or four, elliptical-lance-shaped, nearly smooth. North America, from Maine to New York, Wisconsin, and northward. Will thrive in a shady position in the artificial bog, or in a moist sheltered border in peaty soil.

**CYPRIPEDIUM PARVIFLORUM.**—Resembles *C. spectabile*, but is somewhat dwarfer, and has darker petals and sepals and fragrant flowers. Grows from 1 to 2 feet high. Flowers early in summer, greenish-yellow spotted with brownish-purple; lip bright yellow, 1 inch or less in length. Leaves oval, pointed. Northern States of America; rather common in bogs and low woods. Culture and positions as for *C. arietinum*.

All the foregoing may also be grown in pots, in the soil recommended for each, care being taken to give them an abundant supply of water during the summer.

**Astilbe (*Spiræa*) japonica.**—This beautiful hardy plant may be increased by division of the roots, or by means of cuttings, and plants produced in both ways soon make good flowering specimens, if well supplied with water during spring and summer, when the weather is dry. Divide the old plants into small pieces, each furnished with eyes, and plant them in good rich ground, a foot apart. Plants to be broken up must not have been forced this year. If cuttings are preferred, take them from plants that have done flowering, and strike them in heat. When rooted pot them off into 3-inch pots, and place them in a warm dung frame until they have become well established, after which harden them off. Plants raised from divisions may be put out in the latter end of May or in the beginning of June, well watering them in at planting time. In order to prepare them for forcing, they should be lifted in October, and plunged in leaves, as they root all winter. After they have been introduced into heat, give them plenty of water, or they will not flower.—W. HOWARD, *Bullman*.

## NOTES AND QUESTIONS ON THE FLOWER GARDEN.

**Primula altaica.**—Allow me to commend this beautiful Primrose to the notice of your readers. It is as hardy and as easy to grow as the common Primrose, but, blooming as it does in midwinter, it requires the protection of a cold frame to display its beauties.—J. W.

**Parochetus communis.**—This lovely plant has been blooming here, in a cool house, throughout the winter. In Derbyshire it will not survive the winter in the open air, but requires the protection of a cold frame. I had a very fine plant of it half a yard across in one of my herbaceous borders last summer, but it has perished during the late severe weather.—J. WHITTAKER, *Mortley, near Derby*.

**Odour of Flowers.**—The delicate odour of Pinks and other flowers may be obtained as follows:—Get a glass funnel, with the narrow end drawn to a point. In this place lumps of ice, with salt, by which a very low temperature is produced. The funnel should be supported on an ordinary retort stand, and placed near the flowering plants, when water and the ethereal odour of the blossom will be deposited on the exterior of the glass funnel, and will trickle down to the point, from which it drops at intervals into a glass vessel below. The scent thus obtained is very perfect and interesting, but is apt to become sour in a few days, unless some pure alcohol is added. By this process many odours may be procured for comparison and study. To obtain the odour in perfection the blossom must be in its prime.—*My Garden*.

## GARDEN DESIGN.

### A GARDEN ESTABLISHED IN SIX MONTHS.

THE seeming miracle of a garden and grounds well furnished with full grown trees being created out of a wilderness in a few months is one very easily accounted for and very easily performed if set about in the proper way. Given a wood with a few grand old trees in it, on a pleasant slope towards the south or south-west if possible, and all the rest is easy. Sparing all really fine old trees, let the bulk of the others be cleared away and the roots stubbed up, leaving of course a sufficient number of those which are handsomely grown—a few masses with their original underwood, with occasionally a single tree, if in a good position, even of the smaller growths, and a capital beginning is already made. A large space must of course be entirely cleared for the open flower garden, and some of the main wood left intact and wild for shady untrimmed walks. This commencement, with the subsequent introduction of some fine full-grown shrubs, both deciduous and evergreen, carefully transplanted with masses of their own earth about their roots, will form such a nucleus for a fine garden and grounds as would, if all the trees had to be planted, require from ten to fifteen years to establish. Supposing the operations above described to have been carried through in November, and space for the flower garden planned and laid out at the same time, herbaceous plants, perennial and biennial, might be at once put in, as well as the seeds of many kinds of spring annuals; also an abundance of bulbs and tubers, such as Crocuses, Snowdrops, Tulips, many varieties of Gladioli, as well as a host of other things. With this preparation effected in November, a noble garden and park-like grounds and shrubberies would be the result in the following spring, a result which would have all the appearance of a grand and long established garden belonging to some fine old place.

This suggestion for creating suddenly an improvised garden might appear a somewhat chimerical one, even to the writer, had he not seen a closely analogous plan successfully carried out, and a piece of tangled woodland of some seven or eight acres, possessing no beauty whatever, suddenly transformed into one of the most attractive gardens that can be imagined. The example here alluded to is one belonging to Mr. Leslie, of Courtmacsherry, a picturesque spot situated near the shores of a beautiful bay, and near a remarkably pretty village in the finest portion of the south-west coast of Ireland. The residence, with a moderate-sized garden and shrubberies of the usual character, had been long established, when it occurred to the proprietor, an ardent lover of horticulture, to add an adjoining wood to the old garden, and so make the flower garden and shrubberies the principal feature of the Place. The idea was no sooner conceived than carried into execution; and within less than a year a noble flower garden, in a series of terraces connected by handsome flights of stone steps, with suitable architectural adjuncts, occupied the place of the uninteresting wood, which had not a single remarkable feature about it. The view from the upper turf terrace, or rather level, for it is of very considerable breadth, is extremely attractive; and from that position the middle and lower levels exhibit their broadly-planned geometric design to great advantage, and their large masses of flower colour tell out with wonderfully fine effect. The breadth and grandeur of the effects obtained in this garden are greatly owing to the simplicity of the treatment, the formality of the geometrically-planned flower-beds being rendered less obtrusive by the avoidance of regularly trimmed borderings and the too common pincushion fashion of one line of colour within another. By means of avoiding these obtrusively mechanical arrangements, symmetry of effect is retained while mechanical formalism is avoided. The planting of the flower-beds on the upper level, necessarily seen first on emerging from the shrubberies, is principally on the mixed border system, and consequently harmonises well with the mixed shrubberies with which they stand in juxtaposition. On the next level below, each bed is filled by an undisturbed mass of colour composed of plants of the same kind, furnishing a fine broad sweeping dash of colour in the picture; or the planting of two kinds of plants, but not more, has been resorted to with the view of breaking up the effect of too frequent a repetition of masses of the primary colours, red, blue, or yellow. For instance, the too great brilliancy of a splendid bed of *Gladiolus gandavensis* is tempered by an equal admixture of a fine large-leaved *Ibiscus*—a very successful mixture. A similar effect is produced in another place by the mixture of groups of Sweet Peas with plants of one of the largest leaved of the tobacco tribe. This sounds simple enough, and simple it is, and it is, in short, the very simplicity that is so delightful. On the lowest level, to be first seen at a greater distance, the arrangement of colour is necessarily more trenchant. The strongest colours are used, and are, as a rule, unminged, the distance tending to soften, and

the unmixed colour to impart a sufficient degree of distinctness to the intention of the plan.

To the right of the more or less formal flower garden is a plantation of low evergreen shrubs, irregularly planted, and blending eventually with masses of wood, while to the left is a pretty natural rockery, varied in effect by a natural stream that comes rattling down the slope with the sweet sounds of falling water. It plunges over many impediments of Lichen-covered rock, with curling ringlets of spray, or rather, as Shelley wrote—

It leaps from the rocks  
With its diamond locks,

as it makes its way impetuously down to the lower level. On its way it is made to form a picturesque rocky pool, in which many of the most attractive kinds of water plants are seen, white and yellow Water-Lilies, and the great flowering Rush, and many kinds of Iris, but more especially there are noble plants of the great white Arum, growing most luxuriantly under conditions apparently most favourable, as they are continuously throwing up masses of their grand single-petalled flowers, each an embodiment of grace in its exquisite convolution.

The rockery is well filled in every cranny of vantage with Alpine plants in great variety, several kinds of which flourish amain among these little Irish Alps. In places where the rocks present large smooth surfaces they are occasionally clothed with a profuse growth of the finer varieties of Clematis, such as Jackmani, Sieboldi, and others. In short this portion of the Courtnaesherry Gardens is extremely attractive, and terminates towards the remains of the wood with a broad border of mixed flowers, which, being irregularly planted, blend picturesquely with the adjoining wood and its undergrowth. At the back of the border are Hollyhocks, American Asters, Japanese Anemone, perennial Sunflower, Rudbeckia, rank-growing Campanulas, and other plants which attain from 2 feet to 3 or 4 in height. Towards the middle are clumps of Japan Lilies, both rose and white, and great masses of the common Tiger Lily were in flower at the time of my visit. In front are lower growing plants—Carnations, Verbenas, Lobelias, and others. The herbaceous plants of this irregular border are so intermingled with low-growing shrubs that it has rather the effect of a natural ridge peculiarly rich in magnificent wild flowers than of a skilfully planted flower border.

In all this, which is so pleasing, so untormented, and so generally satisfactory, I do not imagine that any vast amount of high horticultural accomplishments have been lavished; on the contrary, I take it to be the result of pure common sense, guided by the requirements of a naturally refined taste. H. N. H.

**The Finest Fruit in the World.**—The Durian, a fruit about which very little is known in England, but which is reckoned by natives and Europeans in the Malay Archipelago to be the finest fruit in the world, grows in great abundance in Java and Borneo. It grows on a large and lofty forest tree, somewhat resembling an Elm in its general character, but with a more smooth and scaly bark. The fruit is round or slightly oval, about the size of a large Coconut, of a green colour, and covered all over with short stout spines, the bases of which touch each other, and are consequently somewhat hexagonal, while the points are very strong and sharp. It is so completely armed, that if the stalk is broken off it is a difficult matter to lift one from the ground. The outer rind is so thick and tough, that from whatever height it may fall it is never broken. From the base to the apex five very faint lines may be traced, over which the spines arch a little; these are the sutures of the carpels, and show where the fruit may be divided with a heavy knife and a strong hand. The five cells are satiny white within, and are each filled with an oval mass of cream-coloured pulp, imbedded in which are two or three seeds about the size of Chestnuts. This pulp is the eatable part, and its consistence and flavour are indescribable. A rich butter-like custard highly flavoured with almonds gives the best general idea of it, but intermingled with it come wafts of flavour that call to mind cream-cheese, Onion-sauce, brown sherry, and other incongruities. Then there is a rich glutinous smoothness in the pulp which nothing else possesses, but which adds to its delicacy. It is neither acid, nor sweet, nor juicy, yet one feels the want of none of these qualities, for it is perfect as it is. It produces no nausea or other bad effect, and the more you eat of it the less you feel inclined to stop. In fact, to eat Durians is a new sensation, worth a voyage to the East to experience.

THE delicate flowers  
With scented breath, and look so like a smile,  
Seem, as they issue from the shapeless mould,  
An emanation of the indwelling life,  
A visible token of the upholding love,  
That is the soul of this wide universe.

## THE ARBORETUM.

### HARDY TREES AND SHRUBS.

BY GEORGE GORDON, A.L.S.

#### THE IBERIAN MAPLE (ACER IBERICUM).

THIS forms a neat slow-growing deciduous tree, from 15 to 20 feet high, with rigid branches regularly furnished with short, tapering, stiff, smooth brown laterals in opposite pairs. It is a native of Asiatic Georgia, and is found on the mountains that separate the ancient kingdoms of Iberia and Colchis. It was first introduced in 1838. The leaves are rather small, bluntly three-lobed, or sometimes visibly five-lobed, quite flat, cordate at the base, slightly toothed on the edges, of a thick leathery texture, and set on stiff foot-stalks, which are rather shorter than the leaves and tinged with red. They are bright glossy green above, glaucous beneath, and quite smooth on both surfaces, and remain on the tree until rather late in the season. The lobes are broad, oval, slightly pointed, and equal in size. The flowers are greenish-yellow, and are produced in loose terminal corymbs in May. The fruit or keys are of medium size, and smooth, with round carpels and broad wings slightly diverging. The Iberian Maple is well suited for planting singly on lawns, on account of its neat appearance and slow growth. It is the *Acer coriaceum* of botanists; but

*Acer ibericum.*

not that of the nurseries, which is only a variety of the common Sycamore. The length of a full-sized leaf is 4 inches, including the foot-stalk, which is  $1\frac{1}{2}$  inch long, and the breadth is 3 inches.

### EGYPTIAN PETRIFIED FORESTS.

A LOCALITY in the Arabian Desert, abounding in specimens of silicified wood, has been noted in Guide-books and other works on Egypt as the "Petrified Forest." Specimens which I brought from this locality have been described by my colleague, Mr. Carruthers, and referred to two species of Unger's *Nicolaia*. The dicotyledonous and non-coniferous character of the fossil trees was previously determined by Robert Brown, from specimens brought home by Lieut. Newbold in 1812. Soon after my arrival in Cairo this winter, I heard of a new locality in the Lybian Desert, equally deserving, from the quantity of fossil portions of trees, to be called a "petrified forest." The attention of Dr. Grant, an accomplished physician of Cairo, and of Wayman Dixon, Esq., who is superintending the erection of a bridge over a division of the Nile, was directed to a conical hill seen from the summit of the Great Pyramid due west, on the horizon of the Lybian Desert. They thought it might be a ruined pyramid, and rode to the hill. It proved to be a natural elevation, but their journey of about ten miles was repaid by finding trunks and branches, and smaller fragments of trees converted into flint or chalcodony, at the base of the hill, and scattered for a great extent around. Dr. Grant was good enough to accompany me to the locality. We left Cairo in a carriage and pair, at eight a.m., and arrived at the Pyramids of Ghizeh about ten a.m. There mounted donkeys, which had previously been ordered, and rode on to the hill, with Arabs and spare donkeys, reaching its base at 12.30 p.m. Near this I measured a prostrate trunk half-buried in the desert, 42 feet in length and 3 feet in diameter. A branch, 2 feet across at its origin, was sent off at 30 feet from the root-end of the trunk, which then shrunk to 2 feet in dia-

meter. The branch was broken away near its origin, exposing a cavity leading to the larger one forming the hollow of the trunk, indicative of the age of the tree. The whole formed one splendid mass of chalcodony. The knots and concentric rings of growth were conspicuous. Near this, and for a mile or more which we explored, were numerous other specimens of trunks and branches and smaller scattered portions of wood all in the same silicified state. The rounded conical hill, for which the Arabs had no name, and which Dr. Grant proposed to call "Kom Whashab" or "Coombe of Wood," consists of reddish miocene tertiary deposit of the same age as the similarly coloured strata overtopping the cliffs of older tertiary limestone on the opposite side of the Nile valley near Cairo. Some of the tree-trunks had been fractured transversely, and at distances so regular as to suggest a segmental structure. I combed twelve of these sub-equidistant fissures in an extent of trunk of 7 yards. The longitudinal fibres are bent outwards along the fissure, which makes the cherty matter filling it to slightly project; but neither this appearance nor the equal intervals of the cracks are constant, and I come to this conclusion, that the seeming segmentation was due to posthumous change. In several of the trunks the tunnels or tracts of boring larvae, probably of a xylophagous beetle, were obvious. I brought away specimens of the silicified wood, sparing to the utmost the grand trunk, which, however, if the "Lybian petrified forest" becomes one of the "sights" to be visited from Cairo is not likely to last long. It afforded us a seat during luncheon, as a prostrate Oak has done in picnics in Richmond Park. The desert scenery with the summits of the distant pyramids is most impressive; but the retrospect of historical events which they suggested seemed but as of yesterday in comparison with the lapse of time which the mind strove to grasp in speculating on the continent where our seat of stone grew and flourished ere it fell and drifted to the tertiary ocean whose upraised bed now forms the wilderness which stretches away like a boundless sea to the horizon.

RICHARD OWEN.

Cairo, Feb. 7th.

**Old Oak and Yew Trees.**—There are as many Oaks named after William the Conqueror as there are old, feudal towers attributed to Julius Caesar, and there are at least some trees to which even a higher antiquity may be indubitably assigned. The oldest and largest tree of which Windsor can boast is the "King Oak," which Loudon tells us is said to have been a favourite with the Conqueror when he inclosed the forest. It is 26 feet in circumference, and is supposed to be a thousand years old. More famous still is the Winfarthing Oak, near Diss, in Norfolk, which tradition asserts was known as "the old Oak" even in the Conqueror's time. Immediately above the root its circumference is 70 feet, and 40 feet at the middle of the bole. According to the best authorities this Oak is believed to be not less than 1,500 years old! Not many buildings now existing, except in ruins, are so ancient as this tree. In the Conqueror's time it might well be called "old," for it had then seen some 700 summers. It was an old tree when Alfred the Great was lighting the Danes and founding the English monarchy; in fact, it may be said to have lived through the whole "History of England." Another tree, the sober, manly Yew—associated in our thoughts with the peaceful parish churchyard—attains a remarkable size and longevity. Numbers are to be found with a girth of 25 or 27 feet; and there is one at Anker-wike, near Windsor, which is believed to be 1,000 years old, and which, therefore, must have been flourishing in ripe maturity when King John was signing Magna Charta on the neighbouring Runnymede. Another famous Yew grew near Fountains Abbey, whose age, as indicated by the concentric rings of its trunk, must have been about 1,214 years. Scientific deduction was in this instance corroborated by history, for it is on record that, while the abbey was being built, in 1133, the monks were accustomed to take shelter under it from the rain.

**Transplanting Trees.**—The best and simplest contrivance which I ever used for the purpose of moving trees and shrubs up to half a ton in weight was one suggested by Mr. Thomas, when I was carrying out some alterations under his directions some eighteen years ago in the South of England. It was made by a common blacksmith, and the cost was only a few shillings. It consisted of a piece of sheet iron, 4 feet long 3 feet wide, strengthened by two thin bars of iron running lengthways from end to end, 10 inches from each side, and, consequently 16 inches apart; these iron bars were about an inch wide and about an eighth of an inch thick. There were also similar bars of iron riveted across each end, into which four stont rings (two at each end) were inserted. As soon as the tree or shrub was ready for removal the ball was elevated on one side; the short iron platform slid under, and the ball let down upon it. A stont rope was passed through the rings diagonally from end to end, and round the ball and trunk of the tree, to make all firm and secure. One side of the hole

being levelled down, a horse was hooked to the rings at one end, and the whole mass glided off to its new position in little more time than I have taken to describe the operation. The longitudinal bars are of course on the bottom where the friction is, but the transverse bars are on the upper side. For moving shrubs on turf, or on soft ground, the longitudinal bars are scarcely necessary. We had the strongest one made for moving plants on the carriage roads, where the friction was more severe. It will be found in practice that the ends will bend up slightly, thus in some measure reducing the strain on the motive power.—E. HORDAY.

**Cerasus ilicifolius.**—In your issue of the 15th ultimo you inquire whether this has ever been tried out of doors in the south of England. I can reply that here (Isle of Man) it does perfectly well in the open air in favourable situations. I have had a plant of it exposed for several years in but a tolerable position, and it is now in excellent health, though it is not a vigorous grower. Many plants reported to be tender in England do admirably here. Among others, I may cite *Osmanthus*, *Desfontainea*, *Cordylina anstralis* (which grows into a magnificent tree), *Aloysia citriodora*, *Phormium tenax*, many shrubby *Veronicas*, also *Fuchsias*, *Magnolia grandiflora*, *Chamerops Fortunei*, many species of Mexican *Conifers*, &c. Can any of your readers inform me whether *Laurus regalis* has proved itself hardy throughout England? With me it has become a beautiful shrub, and grows with great luxuriance. Its aroma is so peculiar and powerful that I should think it might prove of some commercial or economic value. I would further inquire whether Tree Ferns have ever been tried in the open air in the southern counties of England.—W. F.

**Old Yew Tree.**—In the churchyard here is a very fine and ancient Yew, out of which I am at present having some dead branches cut. The tree is for the most part in a highly flourishing condition, but in one part of its stem there is a large hollow, and it is thereabouts much decayed. It appears to me that all this decayed part which can be reached should be cut out and then painted or tarred over to arrest the progress of the decay, of which there is a good deal, though little compared with the size of the tree, which is well worth preservation, inasmuch as it is about 60 feet in height, covers an area of about 50 feet in diameter, and is 23 feet in circumference at 3 feet from the ground. Possibly some one learned in the preservation of trees would communicate what is best to do in such a case.—MONTAGUE WILLIAMS, *Wooland House, Blandford.*

**Trees and Rain.**—A good deal of needless alarm exists at the prospect of great droughts appearing when forests shall have been cut away. The statements made by Taylor, Humboldt, and others to prove this are of doubtful application. It is true that a country is more moist where forests abound, but the amount of rainfall of a country cannot depend upon the presence or absence of trees. The whole of America from Indiana to the Missouri River is mainly a vast prairie, and yet the rainfall is equal to what it is in the timbered regions of the Atlantic States, or even of Canada and Maine, where there are unbroken forests. If there were not a tree on the whole of the British Islands, they would still be drenched with showers condensed from the warm and damp winds of the Gulf Stream. The Rocky Mountain region is far from being destitute of trees; indeed, there are vast forests; and yet along the borders of the mountains, upon the plains, three, six, and sometimes nine months pass and not a drop of rain falls. Rainfall depends upon climatic conditions, which trees cannot affect, though forests retain water long when it does come. Q.

## NOTES AND QUESTIONS ON TREES AND SHRUBS.

**Measuring the Heights of Trees.**—When the sun is shining so that the tree casts a shadow, set a stick upright near at hand. Mark the extremity of the shadow of the stick and also of the tree. Then as the length of the stick's shadow is to the length of the stick, so is the length of the tree's shadow to the height of the tree.—BETA.

**Planting in Spring.**—Having just purchased some property, I am anxious to plant it with shrubs and trees, and I am desirous of knowing whether it is too late in the season to put them in, or would it be safer to wait until next fall. Are there any particular sorts which would be safe to plant now?—F. H. [Evergreen trees and shrubs, conifers, &c., may be planted with perfect success in spring and early summer. Deciduous trees and shrubs are best planted in the fall, though they may be planted with safety in early spring.]

**The Canadian Elder.** Mr. Williams, of Ormskirk, has written to you in praise of the common Elder and its varieties. I fully endorse his praises, but I would add to them by recommending the Canadian Elder as one of the best autumn-flowering shrubs with which I am acquainted. I saw it in September last year at Kilsnoy, Argyllshire. The garden there are celebrated for the luxuriance and variety of their flowering shrubs. But at that time of year the Canadian Elder was most conspicuous in the woods and shrubberies. It has large cymes of white and pink flowers, and, like all the family, will grow anywhere.—HENRY N. ELLACOMBE, *Bilton Vicarage, Gloucestershire.*

## THE INDOOR GARDEN.

### TODEA WILKESIANA.

THIS is an exceedingly pretty tree Fern, and one which is quite distinct from all others in cultivation. In Australia tree Ferns are said to have trunks that often reach some 60 feet in height and 4 or 5 feet in circumference; and even in our English nurseries and private gardens we sometimes find giant specimens of tree Ferns, the trunks of which have been rooted out and imported like logs of wood. The subject of our illustration, however (for which we are indebted to Messrs. Veitch), acquires no such dimensions; on the contrary, its trunk attains only a height of some 2 feet, and its diameter a little more than an inch. Like other species belonging to the same genus, it is particularly partial to a close moist atmosphere. A minimum temperature of 45° in winter seems to suit it admirably, and even from a few degrees less it sustains no injury. The specimen of this plant now in the Royal Exotic

not stiff and formal, like an Azalea, nor overcrowded with bloom, but graceful in outline, with a profusion of soft-tinted flowers relieved by an abundance of delicate foliage, and you have the Balsam as it ought to be, and can be grown by anyone who will try. First of all secure seed from a good "strain," sow it in a 5-inch pot, using a finely sifted compost, consisting of leaf-mould, loam, and sand in equal parts; cover the seed about an eighth of an inch deep and plunge the pot in a Melon or Cucumber bed, or anywhere where the temperature is about 80°; water sparingly till the plants appear, when they must be well exposed to the light. As soon as they have made their second leaves prepare the required number of 4 or 5 inch pots by having them washed clean and crocked with clean crocks about an inch deep. Then prepare a rich and light compost of loam, leaf-mould, and well-rotted cowdung, or old decayed hotbed manure in equal parts. If the soil is cold, it must be warmed before using by leaving it in a warm house for some hours before potting; for the Balsam is very susceptible of injury from cold or damp, though it does not require a very high

Todda Wilkesiana.

Nurseries has a trunk nearly 13 inches in height, and a wide-spreading crown consisting of over a dozen large and fine fronds of last year's growth, and others in course of development. It is grown in a large glass case in a shady corner of the fernery, in a compost consisting of peat, chopped sphagnum, and silver sand, the pot being plunged in another containing sphagnum, so as to prevent too rapid fluctuations of temperature or moisture. The case is not kept close; on the contrary, one side of it is generally open.

### THE BALSAM.

THE Balsam may be said to be among the best of conservatory annuals. It is easily cultivated, it is amongst the gayest of the gay, and most accommodating in habit. It may be grown as a small, spindly pyramid, in a 4-inch pot, or it may be had in the form of a bush. As a vase plant indoors, it has few equals. Imagine a plant 3 or more feet in diameter at the base, about the same in height, perfectly pyramidal in shape,

temperature to grow it successfully. When everything has been got in readiness, turn the seedlings out of the pot, single them out carefully, and pot them off, one in each pot, taking care not to press the soil too firmly so as to bruise the roots, or injure the soft herbaceous stems of the plants, but see that they are potted up to the seed leaf. When all have been potted, plunge them in some house or pit where they can have a bottom heat between 75° and 80°, and where they can be well exposed to the light and air; water thoroughly with tepid water, and shade for a few days until the roots get hold, when shading may be discontinued, and all air and light possible must be allowed consistent with a day temperature of from 75° to 80°, and bottom heat about the same. Under this treatment the plants will grow rapidly, and branch out freely on all sides; but care must be taken to water, carefully but without stint, when needful. As soon as the pots are fairly filled with roots, but before the balls get matted, the plants must get another shift into 9 and 10-inch pots, using the same soil and the same precautions as before. At this stage also the plants must be trained, for the first time, by pegging the

lower branches down to the surface of the pot, or until they stand out at right angles to the main stem; and to these again must be tied, with soft matting, the second tier of branches. This will be about all that is practicable at this stage, and the plants must be restored to their former quarters, and treated as before.

Those who have limited conservatory accommodation seldom care to have plants more than 2 feet high, and as much or less in diameter; and this size can be secured in a 10-inch pot. When this is the case, the practice is to pick the flowers off up till the second potting, and afterwards to let the plants bloom; and eventually, when they are well grown and hardened a bit, to move them into the greenhouse or conservatory, when they will require abundant waterings with manure water. When plants of large size are desired, the plan of course is to shift on into larger pots—say, 12-inch or 14-inch—and to tie out the branches each time the plants are potted, or oftener if needful, and pick off the flower-buds until within two or three weeks of the time the plants are wanted to bloom. The Balsam will continue to flower for six weeks or two months, if it receives attention in watering and other liberal treatment. When a successional display is wanted, the custom is to sow every two months or so, until August or September. Moderate-sized, well-furnished plants can be got up in a very short time, as the Balsam is a rapid grower. As I have before stated, the plants must be plunged while growing. During summer a cold pit will suit them if there is a slight bottom heat; but, at any time, before removing the plants to the conservatory, the pots must be lifted up a few inches at a time, until they are quite out of the bed, so as to harden the roots a little. The plants will then not be checked by the transfer to the cool and airy temperature of the conservatory. J. S. W.

#### BASKET PLANTS.

SUSPENDED baskets, when well filled with suitable plants, may be said to be invaluable for conservatory decoration. Formerly the plants chiefly grown in such baskets consisted of Orchids, such as Stanhopeas, trailing Dendrobes, and similar plants; but now Ferns, Lycopods, Cacti, and succulent plants of various descriptions are employed for that purpose, and why the list should not be further extended in that direction I do not know. No better way of examining the intricate beauty of some of the smaller Melocacti could be devised, while a basket thoroughly well furnished with plants of *Cereus flagelliformis*, *C. Mallisoni*, and others of like habit, in full bloom, would be a sight worth seeing. The night-blooming *Cereus* would also be a grand subject for this kind of ornamentation. Again, for summer gaiety, what could be finer than a mixture of the brilliant orange, scarlet, purple, and silvery-white *Mecombanthemum*? Of annuals, the *Portulacas* and *Clintonias* might be taken, and for winter and early spring the various kinds of *Tropæolum*, especially the varieties of *T. Lobbianum*, and of the tuberous-rooted species, not forgetting our light and elegant favourites *T. tricolorum*, *T. Jarrattii*, and the lovely blue *T. azureum*. If we want foliage plants, our stoves swarm with such fine-leaved plants as *Gymnostachyum*, *Pittonia*, *Sonerila*, *Panicum variegatum*, and such climbing plants as *Cissus discolor*, *Lindenii*, and *porphyrophyllus*, the latter especially delighting in a position where, like the Ivy, it can root from every joint. Nothing can look more beautiful than these plants when brought between the light and the eye, *Bresinas* and the *Dracenas* being specially beautiful in such a position. Perhaps, however, the finest examples of basket-gardening are the immense masses of the choicer kinds of *Achimenes*, as they may be seen in the Victoria house and large conservatory at Chatsworth. These baskets are very large, requiring, when filled with soil, four or five strong men to lift one, and each is stocked with hundreds of plants; so that when fully grown they form one dense mass of bloom, almost perfect spheres, from 1 foot to 6 feet in diameter, and decorated daily for several months in succession with thousands of flowers. It is singular that the original species, *A. longiflora*, its large-bloomed variety, and *alba*, *patens*, *grandiflora*, and *Verschaffeltii* succeed best, the modern hybrids not thriving at all well. The preparation for these baskets at Chatsworth is almost like the preparation for bedding out in an ordinary

establishment. The caterpillar-like tubers may be seen by the peck, and after a time dozens of shallow boxes with the young plants growing up like small salad. Still, grand as *Achimenes* are in their season, there is another tribe of plants, which is still more effective. These are the *Epiphyllums*, which, when fully developed, form objects of great and novel beauty. *Epiphyllums* are particularly suited to the basket style of decoration, for, to realise their special beauty, the flowers must be seen upon a level with, if not above the eye; and the baskets can be raised or lowered, so as to bring out the bright tints of their richly-coloured flowers. A.

#### BROWNEAS.

THAT fine stove shrub, or rather small tree—*Brownea macrophylla*—is now producing magnificent flower-heads measuring nearly 3 feet in circumference, and of the most brilliant orange scarlet, in the hothouse of W. H. Crawford, Esq., in the vicinity of Cork, this being the third year since it commenced to flower for the first time, it is believed, in the United Kingdom, and for the third time in Europe. The magnificent heads of blossom are produced from the hard wood of the main stem a few inches from the ground, where a swelling first appears, then a crack in the bark, from which protrudes the bud on a short footstalk of about an inch to an inch and a half in length. The flowers commence to open usually in the morning, are at their best about the middle of the next day, and have fallen off before the next morning; so that each head may be said to remain in beauty for about two days. The plant in question is about 30 feet in height, and has a bare stem to the height of about 10 feet, when the branches commence. It produced seventeen of its beautiful flower-heads during the spring of 1872, and, curiously enough, was the only variety that bloomed in that year out of a collection consisting of no fewer than twelve species of this fine genus. These are named *Brownea Leopoldi*, *antioquiensis* (only recently added to the collection), *grandiflora*, *caliensis*, *princeps* 20 feet high, erecta 40 feet high (these two last-named having never yet flowered), *ariza*, *capitata*, *coccinea* (the freest blooming of the whole family), *grandiceps* (which is finely figured in Van Houtte's "Flore des Serres," Vol. VI., tab. 581-2), and *latifolia*, almost as handsome a kind as *macrophylla*, which is now in bloom. The girth of the stem of *macrophylla*, close to the ground, is about 6 inches. There are four other varieties of *Brownea* known to collectors, but not in this collection. These are named *B. leucantha*, *racemosa*, *cauliflora*, and *Rosa di Monte*. Nearly the whole of this magnificent family are indigenous to the mountainous shores of Terra Firma, one of the hottest districts of South America. Two, viz., *B. coccinea* (figured in "Bot. Mag." Vol. 69, tab. 3,964) and *B. Rosa di Monte*, are said to be also indigenous to the West Indies. Of these the first was introduced into England as far back as 1793, but from the amount of room they require, and the age to which they must attain before they flower, they are but little grown by amateurs. Mr. Crawford's gardener has succeeded in crossing several of the kinds that have flowered with him, one with the pollen of the other, and has got them to ripen seeds which are of immense size, resembling a very large flat bean, about two only being produced in each pod. These, on being sown, have germinated freely, and he has now an exceedingly nice healthy lot of young seedlings of from the age of a few weeks to several years, whose foliage, in many instances, shows plain indications of partaking of the nature of one or both parents, and from these, when they bloom, some most interesting results may be expected. W. E. G.

#### PROPAGATION OF ORCHIDS.

THE majority of Orchids are very readily multiplied; still there are some that can only be propagated at long intervals. The value of Orchids does not depend so much on the beauty of the plant or its flowers as it does on the small quantity imported, or the difficulty of its being multiplied in our collections. *Dendrobiums* are perhaps as easy to propagate as any other Orchids. The old flowering bulbs of *D. nobile* may be cut into lengths, the latter being inserted in a common cutting-pan, covering them with a bell-glass, and plunging them in bottom heat. So treated, they break freely. *D. Devonianum*, *D. transparens*, and many others, may be propagated in a similar manner; or the old bulbs may be twisted round the tops of the pots and pegged down among the sphagnum. It is a good plan to have a close case in the Orchid-house, the bottom being covered with a layer of living sphagnum. Then,

as back bulbs are cut from the plants, they should be labelled and laid on the moss, which should be watered or syringed occasionally to keep it fresh and moist. Nearly all Orchids will break freely from the old bulbs in a close humid atmosphere, provided always that there are latent buds on the parts removed. Old back bulbs of *Oncidiums*, *Odontoglossums*, *Zygopetalums*, *Miltonias*, *Maxillarias*, and *Lycastes* may be placed in a cutting-pan, or laid on a layer of moss in a warm, moist situation, where a large proportion of them will root and break freely. *Aerides*, *Vandas*, and *Saccolabiums* can only be propagated by lateral breaks. These last are produced very freely by some strong imported plants that have accidentally lost their leading growth. The same remark applies to *Camarotis*—a beautiful, though neglected, old Orchid—and to the *Angraecums*, *Thunia alba* and *T. Bensonia* are very easily multiplied by cutting up the old pseudo-bulbs into pieces 3 to 4 inches long, and treating them as recommended for *Dendrobiums*. *Phalenopsis* often produce lateral breaks, and occasionally produce young plants on the flower-stems. *P. Ludemanniana* frequently does this, while *Cypripediums*, *Masdevallias*, *Disas*, and most other Orchids, are readily multiplied by division after the plants have attained to a good size.

Seedling Orchids are but rarely met with, although some very good things have been obtained from seed. *Cypripediums*, more especially *C. Schlimmii*, seed freely if fertilised as recom-

that is, seed capable of germination. Orchid seed when obtained should be sown immediately on some fresh living sphagnum in a moist situation, where there is no danger of its being disturbed for twelve months at least. Even after the seed does germinate, it takes the seedlings a long time to make flowering plants; still the raising of seedling Orchids is very interesting for those who have the leisure and inclination to devote to the subject.

Seedling *Dendrobes* and *Cypripediums* have been raised at the Fairfield Nurseries—the latter from imported seed; and Mr. Mitchell, gardener to Dr. Ainsworth, Lower Broughton, near Manchester, has also some very promising seedling *Dendrobes*. Our sketch shows seedling plants about three years old, the result of fertilising *D. heterocarpum* with the pollen of *D. nobile*.

Several hybrid *Cattleyas*, *Laelias*, and *Cypripediums* have been raised by Mr. Dominy, whom we have also to thank for *Cypripedium Harrissianum* and *C. vexillarium*. *Calanthes* are very easy to propagate, for if an old bulb has its top broken off it will often produce two or three young plants round the fracture. The delicate little *Pleione humilis* propagates itself very freely, producing numerous little bulbels on the apex of its old decaying pseudo bulbs. These fall off and root freely into the living sphagnum on the pot-tops. The preceding methods are those generally adopted in the nursery trade, and are equally applicable to private establishments.

Our illustration of *Phajus grandifolius* shows a young plant produced adventitiously on the flower-stem, and also young plants on the flower-stem of *Consul Schiller's Phalenopsis*. This also illustrates a semi-circular raft on which *Phalenopsis*s, *Saccolabium*s, &c., are successfully grown by Mr. Turner, Leicester. Grown in this way, with the roots exposed, is far more rational than to bury the aerial roots in a mass of cold, wet, and often rotten sphagnum, as is generally done when these plants are grown in pots. F. W. B.

Seedling *Dendrobes*.

THE GARDEN-CATALOGUE OF A.D. 1.

In the length of the garden-catalogue as it was in the year One, and as it exists in 1873, we should naturally expect some striking difference, and this not only in regard to familiar and fashionable flowers, but as to commonly cultivated esculents and favourite fruits. The immensity of the contrast between the first and last, it is impossible, however, to conceive without comparison. The ornamental part of our garden contents must needs be enormously greater, seeing that the floral treasures of every country in the world are now represented in England: it is when we look at the list of eatable things that surprise begins to grow: since at the period from which Anno Domini dates, the mightiest nation of antiquity made luxury and feasting one of the chief avocations of life, and appetites such as theirs could not be satisfied without plenty of tribute from trees and plants. Where, to-day, according to our seedsmen's lists, we have the choice of a hundred varieties, there is reason to believe that the Romans had no more than they could count upon their fingers; it is plain that they must have put what they did possess to consummate use, and that the want of an ampler selection was compensated by skill in cookery. The same is true of the variety of the fruits within reach at the time of the Cæsars, though in regard to these the lists of sorts were longer than those of esculent vegetables. Even equivalents for many things in constant use with ourselves were not possessed by the ancients, the Potato, for example, and the Cauliflower; and, among fruits, the Orange, the Pine-apple, and the Cocoa-nut; tea likewise, coffee and chocolate, sago and tapioca; and, though not exactly horticultural, still, like the renowned beverages, a botanical thing as to parentage, that incomparable and immortal leaf which supplies an "own fireside," to every man who fancies it, be he married or single, at home or abroad, Helen's Nephenthe and Paracelsus's elixir vite rolled into one—the leaf that supplies the good cigar. Fancy, had he but known it, the praises of *Nicotiana* that would have flowed from the pen of gentlemanly Horace!

The list of culinary vegetables esteemed by the ancients may accordingly be very soon run through, as with that of the cereals which formed the chief care of the husbandman. It

*Phajus grandifolius*.

*Phalenopsis Schilleriana*.

mended, and the latter species generally comes true from seed. *Disa grandiflora* comes up from seed very freely, and some of the beautiful varieties into which it sports have doubtless originated in this manner. Orchids produce an immense quantity of their membranous, netted seeds, when properly fertilised, but I am inclined to think that but a very small proportion of good seed is borne by plants in this country;

is much the same too, whether we ask what the Hebrews ate in the time of Solomon, or the Egyptians when the Pharaohs reigned, or the classical Greeks, or the Romans under kings, consuls, and emperors. The cultivation of the original sorts began with civilization, and travelled westwards with the pioneers of human progress. In the Old Testament are mentioned Wheat, Barley, and Millet; Beans also, and Lentils (which last constituted a large proportion of the popular food in early times), Cucumbers, Gourds, Melons, and Onions. The monuments and tombs of pre-ægypt contain drawings that illustrate many of the same things, and even the processes of agriculture, with threshing and baking, &c.; while now and then even seeds are discovered. What was cultivated in Greece is known from the literature of that great country; and the additions made by the Romans we learn similarly from the Latin authors. The last-named people had the common Cabbage in its larger and grosser forms, Turnips and Carrots, Leeks, Peas, Chick-peas (the produce of the *Cicer arietinum*) which, like Beans and Lentils, had been extensively used by mankind from time immemorial, and Asparagus; this name including, however, other kinds of succulent shoots, just as in Bath, at the present day, the young flower-spikes of the *Ornithogalum pyrenaicum* are sold as "English Sparrow-grass." They also had various acetarious or salad plants, such as Parsley, Lettuces, Endive, and Sorrel; and a fair proportion of aromatic potherbs, such as Basil, Pennyroyal, Mint, Marjoram, Sage, and Savory; with plants that supply seeds suitable for condiments—Mustard, Anise, Cummin, Coriander, and the like. Capers, Radishes, and Alexanders (*Smyrniun Olusatrum*) likewise seem to have entered into their vegetable bill of fare; and in addition to these, several things which in England have never been employed, such as the rhizomes of the *Arum Colocasia* and the pungent seeds of the *Nigella*. Similarly, in the East, appear to have been eaten the rhizomes of some of the water Lilies, the pods of certain species of Hibiscus, the Almond-like seeds of the *Nelumbium speciosum*, and the bulbs of the *Asphodel*. The *Asphodel* bulbs are what old Homer refers to in the *Odyssey*, as the food of the departed, to whom it was supposed some sort of pabulum would still be important. Various other esculents were resorted to by the inhabitants of different countries, every nation of course finding out what was suitable for food in the products of its own soil, while colonists gradually conveyed the best of these to other lands. Among these odds and ends were various species of *Chenopodiaceæ*, anticipating our bygone use in England of the common mercury (*Chenopodium Bonus-Henriens*), and our modern employment of Spinach; the tubercles likewise that are formed upon the rhizomes of the *Cyperus esculentus*, which possess an agreeable and nutty flavour, and are to this day largely collected in Spain for the manufacture of orgeat, the principal supply being yielded by Valencia. The Garlic, by the way, so esteemed in ancient Egypt, would seem to have been that species of *Allium* we now call, from Ascalon, its original seat, the *Shallot* or *Eschalot*. In oriental countries it is the commonest of the genus, and no doubt is the bulb intended in the memorandum preserved by Herodotus, who says that the list of expenses incurred in the building of the pyramids included the enormous item of 1,600 talents expended in buying Garlic for the food of the workmen. The poorer classes among the Romans used as pulse the seeds of the *Lupinus Thermis*, an amusing allusion to which is made by Virgil, who calls the crop *Tristes lupini*—"melancholy lupines"; the epithet referring not to anything woe-begone in the aspect of the plant, for, like all other Lupines, it is cheerful enough in countenance, but to the dejected look of those who ate freely of the seeds, the bitterness of which has a tendency to draw down the corners of the mouth, as when a child is about to cry. That the word "tristis," in one of its senses, signifies simply bitter to the palate, is quite true, and Virgil himself elsewhere employs it in the literal sense; but the charm of an epithet in the hands of a great poet is, that while applicable as a prosaic one, it makes quicker and livelier appeal to the imagination, and this, no doubt, was Virgil's design. The Lupine in question is still a common article of food with the poorer classes in Sicily. To moderate the bitterness, the plan is now to soak the seeds in salt or sea-water for twenty-four hours, after which they

are eaten without further preparation. Seeds of this Lupine have been found in the ancient Egyptian tombs, along with Chick-peas. In the East, we may add, and probably also in Southern Europe, Sesame, the *Brassica oleifera*, and other plants were cultivated for the sake of the oil obtained by expression from the seeds.

Most of the superior kinds of vegetables in use among the Romans, as well as the cereals, were almost certainly brought in the first instance from western Asia. The particular history of their first culture of course can never be known. Bulbous plants would excite attention before fleshy-rooted ones, since most of the latter owe their excellence to prolonged cultivation, and hence it is that some of the best of these fleshy-rooted vegetables are relatively modern. Think of the wild or indigenous form of the Parsnip or the Carrot as it grows by the waysides in many parts of England, and especially near the sea; how little inducement it seems to offer to the gardener, yet what admirable results have been achieved by patience and skill! These plants are at the same time illustrations,—examples of an almost universal capacity in the vegetable kingdom for improvement under the hand of man. "All our plants," it has been well said, "are capable, more or less, of indefinite improvement. The result gained to-day is simply a prophecy of what may be attained to-morrow, and herein lies the true reward for labour." If progress in particular departments of culture appears to be slower than we may fancy it to have been aforesaid, this comes of the object dealt with now occupying a higher level: the nearer we approach perfection, of course the slower must be the advance. Note likewise the grand assurance given by the consideration of this splendid principle of "improveability," in reference to the food of man throughout the ages to come! While we have a thousand reasons to be thankful for what was accomplished years ago, and as many more for pride in the achievements of to-day, we may cherish no less lively a sentiment of hope in regard to the future, and dread not for an instant the super-abundant populating of the earth foreboded by alarmists and calculators. Nature knows better than to create mouths in excess of food. The gardeners (taking the word in its largest and worthiest sense), with God's help, will act as her agents in preventing that. Though the botanists bestowed the names, it is to the gardeners we owe the conversion of things from the insipid and innutritious condition into one of excellence; and it will be the gardeners who, rightly apprehending the true law of nature, will show that her productiveness will never be outrun by that of mankind. The relation of plants to the needs of man has for its inmost principle the idea of benevolence. Nothing supernatural will ever be needed, and though local deficiencies may arise, and the balance seem disordered, it will never be from failure in the adaptedness of nature to all requirements, let her only be tended skilfully. The same facts show that the gardeners are trustees of the true conservative force of civilization, which constantly depends upon good and plentiful food, seeing that the improvements that have been effected by them are subject to disappearance, and require constant and vigilant industry to be rendered permanent. Caulitowers and Potatoes are guaranteed only to intelligent industry; civilization, and first-class vegetables, Cereals included, go hand-in-hand, and stand and fall together. It must not be overlooked, while speaking of vegetables employed in the kitchen, either as substantial aliments or as conferring delicate relish, that the Romans were acquainted with many of the most precious and remarkable spices and other flavouring products ripened in oriental countries, ascribing many of them to Arabia—then, as still, a land of marvels and mysteries—and which were conveyed westward by the famous merchants who made their way from India by the Persian Gulf and the Euphrates, and thence *via* Damascus, or over the waves that carried Sinbad, and up the Red Sea. Pliny mentions, for example, cloves, mace, cinnamon, pepper, and ginger; also as official substances, cardamoms, catechu, storax, tragacanth, myrrh, mastie, labdanum, galbanum, opopanax, &c. Some of these last were simply Syrian in their origin, and some belong to times far more remote than Pliny's, the names occurring in the Old Testament; collectively they attest the immense extent of ancient commerce.

LEO GRINDON.

## A TROPICAL CANAL.

THE accompanying is an illustration of one of the many beautiful narrow creeks that abound along the great rivers of South America—a region in which vegetation attains the greatest possible luxuriance. In the deep alluvial soils in the great river basins, Palms, Arums, and other tropical types acquire wonderful dimensions, and the contrast of small-leaved and round-headed trees with the Palms and similar stately examples of vegetation has a beautiful effect, which is, moreover, enhanced by the drooping shoots of the giant climbers which hang from the higher trees. The water itself in many cases teems with aquatic plants of the most beautiful kinds: our best tender Water Lily even—the *Victoria regia*—was found in one of the tranquil tributaries of the Amazon.

GARDENING  
AS A  
RECREATION.

I WOULD recommend every man in the autumn of his life to take to gardening, if he has not already experienced its pleasures. Of all occupations in the world it is the one which best combines repose and activity. It is rest-in-work or work-in-rest. It is not idleness; it is not stagnation—and yet it is perfect quietude. Like all things mortal, it has its failures and its disappointments, and there are some things hard to understand. But it is never without its rewards. And, perhaps, if there were nothing but successful cultivation, the aggregate enjoyment would be less. It is better for the occasional shadows that come over the scene. The discipline, too, is most salutary. It tries one's patience and it tries one's faith. And even in the worst of seasons there is far more to reward and encourage than to dishearten and to disappoint. There is no day of the year without something to afford tranquil pleasure to the cultivator of flowers, something on which the mind may rest (using the word in its double sense) with profit and delight. If there is no new surprise, no fresh discovery for you, there is always something to be done. "The garden is a constant source of amusement to us both," wrote Dr. Arnold in one of his delightful letters—he was writing of himself and wife; "there are always some little alterations to be made, some few spots where an additional shrub or two would be ornamental, something coming

A Tropical Canal.

into blossom; so that I can always delight to go round and see how things are going on." In the spring and summer there is some pleasure-giving change visible every morning, something to fulfil and something to excite expectation. And even in the winter flower-culture has its delights. If you have a greenhouse or conservatory, no matter how small, you have an indoor garden, in which you may watch some changes and enjoy the same delights. And if you have not, you may still do something to preserve your nurslings during the rigours of the hybernal season. Indeed, there are few states of life in which floriculture is not available enjoyment. To rich and to poor it is a blessing equally accessible. "As gardening," it was

observed by Sir William Temple, who has had a new lease of life in one of the best of Macaulay's "Essays," "has been the inclination of kings and the choice of philosophers, so it has been the common favourite of public and private men, a pleasure of the greatest, and the care of the meanest; and, indeed, an employment and a possession for which no man is too high or too low."—*Carroll Magazine*.

**The American Aspen.**—This is abundant in the region east of the Cascade Mountains and Sierra Nevada, forming a marked feature of the vegetation of the slopes of these mountains where the forests of the higher lands border the Sage plains of the central desert. Here it is seen in long lines of trees of small size, marking the course of the many mountain streams which are in summer absorbed by the arid surfaces of the plains soon after leaving the mountain sides. Dr. Newberry says:—For a time we were often deceived by the Poplars and Willows, regarding them as indications of the presence of water, but we soon

learned that they were only a sign that water was to be found in their vicinity at some time during the year.

When I could not obtain large pleasures, I put together as many small ones as possible. Small pleasures, depend upon it, lie about as thick as Daisies; and for that very reason are neglected, trodden under foot, instead of being worn in our button-holes. We cannot afford to buy Roses at Christmas, or Camellias at any time; and so we couple Butter-cups with vulgarity; and things that grow in the hedge-side we let wither where they grow, for no other reason than that the king's highway is not a royal garden.—*Douglas Jerrold*.

## SOILS, MANURES, &c.

### VALUE AND APPLICATION OF MANURES.

It is a much easier task to define the constituent elements of manures than it is to lay down any rule for their application. Science can do the one, but to apply manures beneficially, it is requisite that we should, in addition to scientific knowledge, possess an experimental acquaintance with soils of different kinds. In my first article upon the renovation of a garden (see p. 119), I had occasion to speak of farm-yard manure. I shall now, therefore, briefly notice some of the other kinds of manures that are used in the garden.

#### SOOT.

The fertilising properties of soot are not so well known as they ought to be; were its value more appreciated every handful of it would be treasured up for garden use, instead of being allowed to be carried off by the chimney-sweep. It is inferior to guano, it has this advantage, that it can hardly be misapplied. Owing to the nature of its constituent parts it will be found a suitable manure for growing crops of all kinds. Immediately after thinning my Onions and Carrots, which are sown in rows, I place between each drill a good thick layer of soot, and after it has absorbed from the soil moisture enough to thoroughly damp it, with a narrow steel fork I loosen the soil between each row, always taking care to thrust the fork well down in the operation; by this means the soil may be gently stirred without displacing the young plants, thus leaving it open and ready for the next process, namely, a good soaking of water either by hose or other means. This settles the earth around the newly thinned seedlings, washes down through the open soil nearly every particle of soot in a few days, and promotes rapid and luxuriant growth. Upon the appearance of grub amongst my Carrots I repeat this process a second time; indeed, soot may be applied in a similar way to any growing crop with advantage. For twenty years I have annually covered my Peach borders under glass with a coating of it half an inch thick. After stirring the soot with a fork as just described, I then literally inundate the house with water. This is done in autumn about the fall of the leaf or directly after the fruit is all gathered. After the water has subsided and the house become sufficiently dry, a little fresh soil is spread over the whole; this makes all slightly and removes the sooty smell in a few days. The effect of this application on the exhausted trees is soon apparent; the new fruit-buds become plump and round, the young wood in the meantime becoming firm and the skin assuming a healthy brown tint.

#### GUANO.

This may be used in the same way as soot, but in less quantities. Upon the whole, however, guano is not a profitable manure when applied to a well-cultivated garden, its strong stimulating qualities having a tendency to excite vegetables to overgrowth. I have more than once seen Peas stimulated by it, bidding fair to rival Jack's celebrated Bean-stalk in height. Phospho-guano is, however, a safe and beneficial stimulant for pot plants when in a growing state. Instead of applying it in a liquid state, I sprinkle a small quantity upon the surface of the soil in each pot directly after a heavy watering has been given, and in about an hour after that I go over all the pots a second time with the watering pot, giving to each as much water as will stand upon the surface, leaving it to filter through the pot at leisure. After this it will be found that all the finer particles will have been dissolved and absorbed in the soil, without any portion passing through the bottom of the pot. The silicious particles left on the surface gradually dissolve, and are carried into the soil by every fresh application of water to the plants. Let any of your readers try this manure in the way I have described, say upon Camellias, Azaleas, or Epacrises, just when they are about to make their new wood, and they will soon discover its effect in infusing health and vigour into their plants.

#### BONES.

These have long and deservedly been held in high esteem as a suitable manure for every kind of garden crop. The fertilising properties of bones were known to many old gardeners who knew little or nothing of scientific analyses; for they have been found buried whole below fruit trees in some of the

oldest gardens in the country. Bones consist chiefly of phosphate and carbonate of lime, with other kindred elements, and they are also rich in ammonia, making them especially well adapted as a manure for permanent fruit borders. Being slow to decompose, they retain their fertilising qualities for years.

#### NIGHT-SOIL AND PIGEON-DUNG.

Every one in charge of a garden, be it great or small, will understand the necessity of keeping a watchful eye upon these two fertilisers. Though small in quantity, they will yield great results.

#### LIQUID MANURE.

The waste of this about many places is a thing to be deplored. Will neither facts nor figures convince people of its value and of the loss which they sustain in allowing it to escape? Mr. Hobday, writing upon this subject (see p. 145), truly observes that the apathy of those immediately concerned in the matter prevents the utilising of liquid manure as a fertiliser; for about gentlemen's establishments this can only be properly done with the concurrence of some one in authority. Any one about to adopt measures for utilising the liquid that flows from either kitchens, stables, or cow-houses, I would advise that only one tank be not made for its reception, but tanks large enough to hold several tons. My impression is that the best means of utilising such liquids as flow from kitchens, water-closets, and wash-houses, is to make a large tank, the bottom of which should be laid with perforated tiles or flags; over that a layer of charcoal and fine washed gravel should be placed to the depth of 18 inches; through this tank all liquid from the common sewer should pass, leaving behind a deposit of solid matter that would be rich in fertilizing properties. Liquid from the stable and farm-yard can only be applied to the garden during the spring and summer months, but it may be made available at all seasons if combined with solid matter, *i.e.*, if a tank or tanks similar to those just described (with the exception of the filtering bed), were filled with dry earth of a heavy texture. A tank for this purpose, too, can be made for little or no expense: take a few loads of clay and a load of fine soil, thoroughly well worked together to the consistency of soft putty. After digging out the tank, and the bottom being laid, a course of bricks or stone should be laid upon it all round, about 10 inches from the side, thus leaving an empty space between the bricks and solid earth to be filled in with puddled clay; in this way the sides may be built up until the whole is finished, making a tank that will serve its purpose for a generation if kept moist and free from roots of trees. Soft water tanks may be made in this way of any size.

#### WOOLLEN REFUSE OR SHODDY.

I have used this extensively in the preparation of a new garden, and for Vine borders which I had under my care for sixteen years after its first application to the soil, and during that time I used it less or more, mixed up with farm-yard manure, for various purposes; and as far as my experience of it goes, I had every reason to be satisfied with the result. I would recommend any one preparing new Vine borders to lay a thick coating of this material over the rubble in the bottom of them (if their borders are prepared in this way); it prevents the loose earth from filling up the crevices, and acts as a sort of sponge when the borders are watered, at the same time preventing all minute particles from passing away with the water. Some of our agricultural chemists have placed woollen refuse very high in the scale of manures; if we take into consideration the different materials that compose it, they do not over-estimate its properties. Wool and vegetable fibre, saturated with the best animal oil, constitute its principal parts; indeed the pressing of oil out of woollen waste has become quite a branch of business in the West Riding of Yorkshire and elsewhere. Woollen refuse is slow in decomposing, and for this reason some doubt its fertilising properties. In Italy long before this material came to be noticed in this country, woollen rags were used in the renovation of exhausted Orange and Lemon trees; a circular trench in some cases was dug round the trees at a little distance from the stem, and filled in with rags mixed with earth, and firmly pressed down.

#### WOOLLEN REFUSE AS A FERMENTING MATERIAL.

No material with which I am acquainted can in any sense be

compared with this as a fermenting material; when laid together in any quantity spontaneous combustion often takes place in it. When I first began to use it as a heating material upon my early Vine borders, I was taught a lesson that I shall not soon forget; people talk of setting the Thames on fire, but I succeeded in setting a little volcano in operation in my kitchen garden. After all this, however, I used it for the purpose of heating my Vine borders for many years; besides its heating property, owing to its oily nature, it prevents wet from passing through it to the soil beneath; and from what I have seen of it, I am surprised that the material is not more appreciated by gardeners, both as a fertiliser and as a warming material, than it is. J. T.

## THE KITCHEN GARDEN.

### THE VARIETIES OF THE GARDEN PEA.

#### H.—MARROW PEAS.

Ripe seed white, large, smooth, uneven, compressed, irregular, or egg-shaped. Skin thick. Foliage blotched.

**Paradise Marrow** (*Champion of Paris; Excelsior Marrow; Knight's Excelsior; Stuart's Paradise*).—This was introduced in 1851, and in my published description at the time, I remarked—"This is a novelty which fully maintains the high character with which it was brought out. It is as yet very little known, having appeared at a time when the public were somewhat awakened to the necessity of caution with which new varieties ought to be received. As regards this, however, there need not be the slightest misgiving, as I have found it to be one of those which must ultimately become one of the standard sorts if preserved in its present true character. The pod is of very large size, remarkably well filled with a deliciously flavoured Marrow Pea, and is fit to be gathered as soon, or at most within a day of the Ringwood Marrow. With such properties, therefore, everyone will allow it is a variety well worthy of general cultivation. The plant is of a strong and vigorous habit of growth, with a stem from 5 to 6 feet high, which is branching towards the top. The pods are generally single, but frequently in pairs, about 4 inches long, nearly three-quarters of an inch wide, remarkably well and closely filled with from seven to nine large Peas, and when they begin to ripen they are thick-backed, succulent, and fleshy. The ripe seed is white, round, and smooth. This does its work very quickly, at least much more so than some others; for although it came into bloom five days later than the Ringwood, it was not, even at the utmost, more than two days behind it in podding.

**Dixon's Early Dwarf Paragon**.—In its habit of growth this resembles Bishop's Early Dwarf. The plant is from 2 to 2½ feet high, with a robust branching stem, which bears from sixteen to eighteen pods, generally in pairs. They are of a fine deep green colour, but do not fill well, containing from five to six medium-sized Peas. Ripe seed large, white, flattened, and indented. It comes into use at the same time as Paradise Marrow and Bishop's Long-podded.

**Harrison's Perfection**.—Plant with a robust habit of growth, having a thick succulent stem, 3 to 3½ feet high, and large dark green foliage. The pods are produced in pairs from every joint, averaging sixteen or eighteen on a plant, but they are very irregularly and badly filled, and contain only from four to six Peas. The Peas are large and thick-skinned. Ripe seed white, medium-sized, and somewhat Lentil-shaped. When this was first introduced it was considered a great acquisition as being an early dwarf Marrow Pea, and as such it would have deserved all that was said in its favour, provided it had not the very objectionable property of filling irregularly. The pods early assume the appearance of being ready for use, but when opened are found to contain half-grown Peas, four to six of which only come to maturity. It ripens at the same time as Prizetaker and Paradise Marrow, and is some days later than Advancer, which has the same habit, is far more productive, and has the additional advantage of being a sweet wrinkled Pea.

**Laxton's Prolific Long Pod** (*Laxton's Prolific Selected*).—It is to be noted that there are two varieties of Peas in cultivation under this name; one has the ripe seed white, and the other is mixed white and olive. The former, with white seed, is the true, and the latter is merely an inferior stock of Prizetaker Green Marrow. The true plant is of a robust and vigorous habit of growth, and with large pale-blotched foliage. The stem is from 5 to 7 feet high, producing from twelve to fourteen pods, which are in pairs. The pods are very large, of a pale green colour, broad, much curved, and pointed, and containing from seven to nine medium-sized Peas. Ripe seed white indented. The seed was sown on the 23rd of February. The first,

flowers appeared on the 1st of June, and the plants were in full flower on the 5th. The slats appeared on the 11th of June, and the crop was fit to gather on the 25th—that is, within a day of Paradise Marrow.

**Thurston's Reliance** (*Reliance Marrow*).—The plant is a strong and very robust grower, always with a simple stem, which is 6 to 7 feet high. At 3 feet from the ground the pods begin to be produced, and are regularly placed at every subsequent joint, even to the extremity of the plant, numbering in all from ten to twelve on each. The pods are generally single, but sometimes in pairs, from 3½ to 4½ inches long, and three-quarters of an inch broad. They are very broad and flat, which shape they retain even when quite filled. The under edge is very much of a scimitar shape, and the upper is slightly curved and tapering gradually to the point. They are of a deep bright green colour, and the surface quite smooth, containing from seven to eight Peas in each, which are large, nine-twentieths of an inch long, seven-twentieths broad, and the same in thickness. The ripe seed is white. This is a very distinct and very useful Pea, an abundant bearer, and the pods are of a fine deep bright green colour, which is a recommendation to it when grown for market. It comes in at the same time as the Auvergne, but it is of a more tender constitution.

**Queen of Dwarfs**.—A very dwarf-growing variety, not more than 6 to 9 inches high. The stem is thick, succulent, and sometimes branching, and the foliage of a dark blue-green colour. Each plant produces about four or six pods, which are of a curious elliptical shape, and rarely contain more than three or four large Peas. Ripe seed white, medium-sized, egg-shaped, unevenly compressed. This is a very worthless variety, and unworthy of cultivation for any purpose whatever. The plant is so remarkably tender, that even in favourable seasons it does not develop nor fill its pods freely. In summers like the last it is chilled with cold, and in those that are warmer or more genial it is almost invariably attacked with green fly.

**November Prolific**.—The plant is 2 feet high, with dark green foliage. The stem is rather robust, generally simple, but occasionally branched, and bears from twelve to sixteen pods. The pods are generally in pairs, rather short, and contain from four to six Peas in each. Ripe seed white, medium-sized, smooth, and compressed. It is two to three days earlier than Victoria Marrow. This somewhat resembles in growth the Royal Dwarf, but is very inferior to that variety, and, in fact, is not worth growing for any purpose.

**Egg**.—This is a very old variety, and long known by the name of Black-eyed Susan, from the seed having a black hilum or eye. The plant is of a strong and robust branching habit of growth, and from 7 to 8 feet high. It produces about eighteen pods, which are almost always in pairs, and these contain about seven good-sized Peas, which are large and oval, like a horse-bean. Ripe seed white, large, egg-shaped, and with a black hilum. This, though an abundant bearer, is quite a worthless variety, and it would be difficult to say for what object it is cultivated. The Peas have a very thick skin, and a coarse Bean-like flavour, and when cooked are generally of a dusky brown colour.

**Victoria Marrow** (*Waterloo Marrow; Giant Marrow; Tall Marrow; Wellington; Royal Victoria; Gibbs' Defiance*).—The plant is of a strong and vigorous habit of growth, having a simple stem from 6 to 7 feet high. The pods are produced near the top of the stem, sometimes singly, sometimes in pairs, in about equal proportion, and contain from five to seven very large Peas. Ripe seed white, large, uneven, and roundish.

**Princess Royal**.—The variety under this name grown in the Chiswick Garden this season proved to be as early as Paradise Marrow and Laxton's Prolific Long-pod. The true Princess Royal, raised by Dr. Maclean, and grown in the trial of 1860, was as late as Tall Green Mammoth, and seven days later than Victoria Marrow. In the true variety the plant is 3 feet high, a strong and vigorous grower, with dark green foliage. The stem is generally simple, but occasionally branched, bearing from ten to twelve pods, which are usually in pairs. The pods are large, and have an attractive appearance, but they fill slowly and indifferently—so much so that when opened they average only from three to six large Peas in each. Ripe seed large, round, uneven, and white.

**Dancroft Prolific**.—The plant very much resembles the Victoria Branching in habit. It is 3 feet high, robust, and frequently branching, and produces from twelve to sixteen pods, which contain from seven to eight Peas of good size. This is an abundant bearer, and four or five days later than Victoria Branching, to which it is not superior.

#### III. GREEN MARROWS.

Ripe seed of a mixed white and olive colour, either small, round,

and pitted, or large, irregular, and uneven. Foliage dark green and blotched. Pods dark, bluish green, very glaucous.

**William I.**—This is one of Mr. Laxton's new cross-bred varieties, and is the earliest of all the Green Marrow Peas. It is nine days earlier than Prizetaker, and ten days earlier than Laxton's Supreme. The plant is from 1½ to 5 feet high, somewhat slender in growth, being in this respect similar to the Early Frame class. Stem simple, producing from fourteen to sixteen pods, generally single, but frequently in pairs. The pods are long and very handsome, of a dark bluish green colour, covered with a thick bloom like Prizetaker, and contain from seven to eight fair-sized Peas, also of a dark green colour. The ripe seed is small, round, indented, of a mixed white and olive colour. This received a first-class certificate from the Royal Horticultural Society.

**Unique.**—This is another of Mr. Laxton's cross-breeds, which is five days later than William I. It was obtained by crossing Laxton's Prolific and Little Gem. The plant is of the same habit as Tom Thumb and Little Gem, and is from 1 to 1½ foot high. The stem is moderately robust, branching, and producing eight to ten pods, which are usually in pairs. The pods are rather long, broad, slightly curved and pointed like those of the Blue Scimitar, and of a fine dark green colour, each containing from six to eight bright green Peas. Ripe seed is parti-coloured. A fine long-podded and prolific early dwarf Pea, to which a first-class certificate was awarded by the Royal Horticultural Society.

**Prizetaker** (*Bellamy's Early Green Marrow; Prizetaker Green Marrow; Rising Sun; Leicester Defiance.*)—The original name of Bellamy's Early Green Marrow has now been entirely superseded by that of Prizetaker. In 1860, when the latter name was new, and the two Peas were grown side by side, I could not see any difference between the two. The old Early Green Marrow, from which this is a selection, is an inferior variety, and now not worth growing. Prizetaker is 1½ feet to 5 feet high, of a vigorous habit of growth. The stem is sometimes simple and sometimes branched, and produces from twelve to eighteen pods. The pods are in pairs, very rarely single, and of a deep bluish-green colour, covered with a thick and distinct bloom; they contain six to seven large Peas in each, which are of a dark bluish-green. The ripe seed is small, round, and of a mixed white and green colour. It is as early as Ringwood and Paradise Marrow.

**Laxton's Supreme.**—This has much the same character as Prizetaker, than which it is one day later in coming into use, and the pods and foliage are of a paler green. The pods are very large, long, broad, and are not so well filled as they appear to be, yet they contain from seven to nine large Peas. The ripe seed is olive green, and indented. This is a large and very handsome Pea.

**Laxton's Superlative.**—This is the largest-podded Pea in cultivation. It was raised by Mr. Laxton from crossing Ne Plus Ultra and a hybrid of Supreme. The plant is very robust in its habit of growth. The stem, which is strong, succulent, and not branching, is from 7 to 8 feet high, with large, broad, pale foliage, producing from fourteen to fifteen pods, generally in pairs. The pods are very large, being 7 inches long, broad, and somewhat irregular in their outline, much curved and pointed, and of a pale green colour; they contain from seven to nine large pale green Peas. Ripe seed flattish, parti-coloured. This large and handsomely-podded Pea does not fill very well, many of the pods being only half full. It received a first-class certificate from the Royal Horticultural Society.

**Matchless Marrow** (*Milford Marrow; Steadsett Marrow.*)—Plant 5 feet to 6 feet high, of strong and robust habit of growth. The stem is always simple, and bears from twelve to sixteen pods. The pods are generally in pairs, rarely single, and contain from six to seven very large Peas. The ripe seed is large, uneven, variously and irregularly shaped, and of a white and olive colour mixed. Sown February 19th, bloomed June 13th, slatted June 28th, ready for use July 15th. This is a great bearer, and produces large, plump, well-filled pods, which come into use ten days after Prizetaker, but it is a tender variety.

**Garbutt's Amazon** (*Denger's Early Prolific Green Marrow.*)—Plant a strong robust grower, 5 feet to 6 feet high, having a simple stem, which produces not more than six pods. The pods are either single or in pairs, and contain six large Peas in each. Ripe seed large white and olive mixed, uneven, variously and irregularly shaped. This is very much in the way of Matchless Marrow, but comes into use five or six days later. It is also much less productive, and the pods, which are few, fill indifferently, so that it is not a desirable variety. Is it not the old Tall Green Marrow?

**Sutton's Berkshire Hero.**—This is a much taller and stronger grower than the preceding, and five to six days later in all its

stages. The plant is seven feet high, and produces eight or ten large pods, which contain from six to seven very large Peas. The ripe seed is larger than that of the preceding and of Matchless Marrow, uneven, variously and irregularly shaped, and of white and olive colour mixed. This is a very late Green Marrow, being nineteen days later than Prizetaker.

**Mossy podded** (*Goat's Pea; Oyster Pea; Blackney Marrow; Australian.*)—The plant of this variety is 6 to 7 feet high, of a strong and vigorous habit of growth, with deep green foliage, which remains green for a lengthened period. Stem generally simple, producing from twenty to twenty-four pods, mostly in pairs. The pods are long, slightly curved, full, and rounded, of a bright green colour, and frequently covered, especially where shaded, with a rough granular excrecence, whence the name of "Mossy Podded." They contain from seven to eight medium-sized deep green Peas closely packed, and which are inferior in flavour. This is a very late Pea. Sown on the 23rd of February this year it bloomed on the 20th of June. Slats appeared on the 24th, and the pods were ready to gather on the 3rd of July.

(To be continued.)

#### MESSRS. VEITCH'S NURSERY, CHELSEA.

THERE is probably not in existence a more famous gardening establishment than that of the Royal Exotic Nursery at Chelsea, of which we this week give a bird's-eye view, taken for THE GARDEN a few weeks ago. The establishment is so compactly and well arranged for its purpose that a view, which serves also some of the aims of a plan, may be useful and interesting.

This establishment, so interesting at all seasons, is scarcely less so now than in the height of summer, when flowers are plentiful. The entrance from the King's Road at once places us in a cool conservatory, which contains Palms, Aracarias, Dracaenas, Tree Ferns, &c., suitable for conservatory and greenhouse decoration. To the left is the seed department, and to the right the offices, which have recently been newly built and much enlarged. Proceeding down the conservatory corridor, which is filled with beautiful plants of various kinds, we pass a museum on the left richly stored with curiosities sent home from foreign countries by different collectors belonging to the firm, but chiefly with contributions from Japan and the South Sea Islands, made by the late Mr. John Veitch. The corridor itself terminates in a large house especially devoted to Tree Ferns of various heights, and consisting of the best greenhouse kinds, such as *Dicksonia antarctica*, *Cyathea dealbata*, &c. There are also some specimens of the curious *Todea arborea*. On leaving the Tree Fern-house we come to what is called "The Square," from which the eye is at once carried to the large *Camellia*-house at the Fulham Road entrance to the nursery. Each side of the square is ornamented with rockwork thickly planted with herbaceous plants; also strong Ivy, Clematis, &c. the beds between the rockwork and walk being decorated in summer with sub-tropical and other plants. The square itself is surrounded by eight houses, space being only left for the main walk between them. Two of these houses are devoted to fine collections of Palms, three to fine foliage hot-house plants, such as *Marantas*, *Anthurium*, *Crotons* (including all the best novelties belonging to that fine genus) *Cyanophyllums*, &c.; one to *Nepenthes*, which grow with a luxuriance only equalled by that in their native habitats; one to *Caladiums* and similar plants; and one to greenhouse Aracarias, such as *Rulei* and the Norfolk Island Pine, of which there is a fine stock of extremely handsome plants struck from cuttings.

On leaving the square by the Aracaria-house we arrive at the rock Fernery, a charming spot richly ornamented with Ferns, but not heated in any way except by being placed between an Orchid-house on the one side and a warm Fern-house on the other. In this rock Fernery, with simply a glass roof protection, often penetrated by frost, many greenhouse Ferns, such as *Woodwardia radicans*, *Dicksonia antarctica*, *Lomarias*, and *Adiantums* thrive admirably; and amongst evergreen hardy Ferns which succeed here may be particularised *Lomaria chilensis*, *Lastrea Standishii*, *Lastrea opaca*, and others. Many flowering plants, such as Winter Aconite, Snowdrops, Lily of the Valley, and Solomon's Seal are also interspersed amongst the Ferns; even variegated *Begonias* do well in the

BIRD'S-EYE VIEW OF MESSRS. VEITCH'S NURSERY, KING'S ROAD, CHELSEA.

same temperature, becoming dormant in winter, but producing very fine leaves during the summer months. Passing to the warm Fern-house we notice good specimens of *Davallia Mooreana*, *Platycecum grande*, *Adiantum Farleyense*, and others; also various sorts of *Trichomanes*, *Leptopteris superba*, and similar useful species. From this house we pass to the greenhouse Ferns, where there are *Gleichenias*, fine masses of the Killarney Fern, and *Trichomanes* requiring greenhouse treatment, a beautiful specimen of the *Todea Wilkesiana*, and many others, together with a good stock of young plants of the more popular kinds. Contiguous to the Ferneries is the Aloe-house, which contains many fine kinds of *Agaves*, and also beautiful specimens of *Phormium tenax variegatum*, *Colensoi*, and others.

Retracing our steps through the Fern-houses and rock Fernery we come to the Orchids, of which there are no fewer than fourteen houses, in which these ever charming plants are divided into two collections; one containing the larger quantity, and at which we first arrive, being called the business collection, the other being a select collection made by the late Mr. Veitch, and which is still kept up. The first house reached on leaving the Fernery is one furnished with *Cattleyas*, *Coelogyne cristata*, and plants requiring similar treatment; next we visit the warm *Cattleya*-house, and then to the *Dendrobium*-house, the *Vanda*-house, followed by the house devoted to East Indian Orchids and the *Cypripedium*-house. In all cases the centre stage is devoted to the larger specimens, the young stock being on the side benches.

Turning to the left, after leaving the *Cypripedium*-house, we pass through three compartments devoted to cool Orchids, such as *Odontoglossums*, *Lycastes*, *Anguloas*, and here terminates what is termed the business collection. We then pass through to the collection formed by the late Mr. Veitch. We enter by a north portico, where, without any heat at all, *Lælia autumnalis*, *Barkerias*, and similar beautiful Orchids, seem to thrive admirably. We then enter the *Odontoglossum*-house, where a fine collection, including the rare *O. Andersonianum*, is just now in perfection. Next we arrive at the *Vanda*-house, in which are fine specimens of various East Indian Orchids, including the rare *Vanda insignis*; also *Aerides quinquevulnerum*, in very fine condition; *Aerides Larpentæ*, *Phalanopsis* and others. On the front stage, *Cypripediums* luxuriate. From thence we pass into the *Lycaste*-house, in which there is a fine collection of that popular class of Orchids, and where we also noticed the beautiful *Dendrobium Wardianum*, *Bensoniæ*, and *Falconeri*, all in fine condition, together with *Vanda cœrulea*, *Oncidium Rogersii*, the new *Odontoglossum vexillarium*, and other rare kinds. The *Cattleya*-house, at which we next arrive, contains a nice collection of that showy class of Orchids, and there is also another—formerly an East Indian house—now filled with a miscellaneous collection of plants, above which Orchids are suspended from the roof. Six more smaller houses, filled with *Odontoglossums*, *Cypripediums*, *Masdevallias*, *Phalanopsis*, and other popular genera, complete the number of houses devoted to Orchids. Retracing our steps to the *Cypripedium* house we enter a long narrow house devoted during the summer to flowering Orchids and other choice plants, and filled at present with *Dracena terminalis* and similar plants remarkable for the beauty of their foliage. This house leads into another devoted to the flowering plants more generally used for decorative purposes, and at present gay with *Hyacinths*, *Tulips*, and other Dutch bulbs. Through the whole of the houses hitherto enumerated, we have passed without once going out of doors since we entered at the King's Road, so complete is the general arrangement of the glass-houses in this fine establishment. We now, however, return to the central walk and find ourselves in close proximity to the propagating department, to which four houses are specially devoted. Proceeding up the walk in question, we come to the stove for flowering plants, gay at present with *Poinsettias*, *Aphelandra Roczii*, and other winter-flowering plants; then we arrive at a high lean-to house, devoted to foliage plants suitable for room decoration; and beyond this is a house devoted to greenhouse *Rhododendrons* and similar plants. Opposite these are two greenhouses, furnished with specimen and half specimen flowering plants, and then on each side of the

main walk are arranged a series of most useful houses, built low, and thus permitting the plants to be grown close to the glass. These houses contain the general collection of young greenhouse plants, also *Azaleas*, *Epacris*, flowering *Rhododendrons*, *Begonias*, stove and greenhouse climbers, *Amaryllises*, and plants of a similar description. Beyond these again come on the left-hand side two houses devoted to soft-wooded plants and florist flowers, one being now filled with *Pelargoniums*; the other with *Bouvardias*, *Cyclamens* in bloom, *Primulas*, and other plants of that sort. Opposite these is the aquarium, where formerly the *Victoria regia*, or Royal Water Lily, grew luxuriantly when scarcer than it is at present, but now filled with handsome specimens of *Palms* and various fine-foliaged plants. Behind and parallel to the two houses for florist flowers are two long houses and a series of pits, all devoted to the culture of this class of plants.

Leaving the aquarium, one comes to what is called the "Flower Garden," where are tried all new kinds of bedding plants; and here also is cultivated a large collection of *Chrysanthemums*, the more select kinds of herbaceous plants, &c. We then come to large glass houses, the two first of which are devoted to the large specimen *Azaleas* which have done such good service at our great metropolitan exhibitions; then follow two large houses filled with *Camellias* in tubs and pots, all of the best kinds and flowering nicely; the whole terminating with the large *Camellia*-house which forms the entrance to the nursery from the Fulham Road. This house is planted with about forty of the very best kinds of *Camellias*, and contains besides a fine lot of pot plants, standing between those planted out. The entrance to this house, which stands somewhat back from the public road, is decorated during the summer with standard and pyramidal *Bay trees* and plants of a similar description. On the left of the *Camellia* house are four large houses devoted to pot Vines, of which some 2,000 are annually grown here; and there are also here two houses devoted to the propagation of the soft-wooded plants.

It will be seen that we have only taken a cursory glance at the contents of the nursery as we have walked through it. We have not even noticed the eight or ten houses devoted to new plants. These, being less conspicuous than the others, are not seen in the ordinary way; they, however, contain a fine lot of new *Crotons*, *Dracenas*, &c.

We may, perhaps, be allowed to add just a word or two in reference to the heating apparatuses employed in this nursery. Many kinds of boilers have been tried in it, and the result is that all, as it becomes necessary, are being replaced by the "Trentham" boiler, which is considered to be both safe and economical—two great considerations in an establishment where, during the winter, as many as fourteen fires are kept burning.

## THE LIBRARY.

### HANDBOOK OF HARDY TREES, SHRUBS, AND HERBACEOUS PLANTS.\*

THIS tolerably good-sized handbook of 657 pages is so exceedingly well got up as to reflect the highest credit on the eminent firm who have published it. It is based, as the title-page informs us, on the well-known "Manuel de L'Amateur des Jardins" of MM. Decaisne & Naudin, and is illustrated by the fine woodcuts of the first three volumes of that work. These of themselves are sufficient to embellish and enhance the appearance of any treatise on horticulture, and form no inconsiderable part of the merit of the volume before us. On looking through its pages, we find that it is divided into two parts, the first containing descriptions of a selection of species which the compiler considers most eligible for general cultivation. This will be found useful by those who do not possess an extensive knowledge of plants, or who cannot boast of a garden of more than moderate size. Such will find here an enumeration of good plants sufficient to supply all their present requirements. The advanced gardener, however, be he amateur or professional, will look in vain for an account of

\* "Handbook of Hardy Trees, Shrubs, and Herbaceous Plants." Based on the French Work of Messrs. Decaisne & Naudin. By W. B. Hensley. London: Longmans, Green, & Co. 1873.

many of the finest introductions of the last ten years. In this respect we consider the book falls short of the wants of the present wide-spread and daily increasing knowledge of horticulture. The space occupied by descriptions of well-known British wild plants might have been more worthily devoted to some notice of such brilliant subjects as *Dianthus alpinus*.

The Perfoliate Honeysuckle (half natural size).

*Lithospermum petraeum*, *Gentiana Bavarica*, *Anemone blanda*, *Sparaxis pulcherrima*, *Saxifraga longifolia*, and many others which are now in pretty general cultivation, but which, we are disappointed to find, have either been passed by altogether in the selection or merely alluded to by name. However, as a book of reference, within its limits, the descriptions given,

Evergreen, or Trumpet Honeysuckle (half natural size).

although frequently of the briefest, may be consulted with advantage.

The second part (which from the proportion that it bears to the first part might have been more justly printed as an appendix) proposes to treat of Practical Gardening. The remarks here are perhaps too general to be of much service to the inexperienced, and the subject, which from its nature requires a considerable amount of detail, would have been

more wisely dealt with in a separate volume. The principles of culture are well laid down, but the attempt to compress within the limits of a few pages all the essential points of the successful treatment of various classes of plants must ever prove unsatisfactory. Our candid opinion is that too much has been aimed at. A full enumeration of *all* the best subjects in each genus, with a little expansion in some of the descriptions, excluding all other matter, would have rendered the work more valuable to the vast majority of those who may desire to possess it.

We extract the following account of the Honeysuckles as a specimen of some of the best of the selections and descriptions, with their accompanying illustrations:

LONICERA.

Erect prostrate or climbing shrubs with opposite simple entire or lobed deciduous or persistent leaves, and cymose or capitate, often fragrant, flowers sometimes adhering together by the ovaries in pairs. Calyx-limb of five often unequal teeth. Corolla tubular or bell-shaped, gibbous at the base in some species, with the limb oblique or two-lipped. Stamens five. Fruit a fleshy two or three-celled berry. There are upwards of eighty species in the temperate and warm regions of the North. This genus was named in honour of the German botanist Lonicer. There is great confusion in the nomenclature of the Japanese and Chinese Honeysuckles, arising probably from the fact that many of them are garden varieties.

1. *L. Periclymenum*. Honeysuckle or Woodbine.—This favourite indigenous shrub is surpassed by none of the exotic species in the profusion and fragrance of its flowers, but for brilliancy of colouring there are many superior. Flower-heads terminal, peduncled; upper leaves sessile; berry crimson. There are several improved varieties, including the Dutch, *L. Belgica*, the Oak-leaved, *L. quercifolia*, and late red, *L. serotina*, and one with variegated foliage of little merit.

2. *L. caprifolium*, syn. *Caprifolium italicum*.—This species strongly resembles the preceding in the colour of its flowers, but the flower-head is sessile and the upper leaves connate. A native of the South of Europe.

3. *L. Etchusa*.—Flowers orange-yellow, capitate; heads pedunculate. Upper leaves connate, young ones hairy beneath. A native of the South of Europe, flowering in May, though not so freely as some.

4. *L. sempervirens*. Evergreen or Trumpet Honeysuckle.—This in its different varieties is one of the handsomest species in cultivation, bearing its scarlet inodorous flowers in great profusion for a considerable period in summer. The leaves are quite glabrous, oblong or rotundate, glaucous beneath, and persistent during the greater part of the winter. The variety named *Bröwuii*, in which the flowers are of a brighter hue, is one of the best. It is a native of North America. *L. coceinea* and *L. pubescens* are allied species from the same country.

5. *L. brachyphylla*.—One of the best evergreen species. Leaves oval or oblong, glabrous and shining, with short hairy petioles. Flowers medium size, in pairs, pale yellow, and very sweet-scented. There is a handsome and very desirable variety, named *aireoreticulata*, in which the foliage is beautifully netted or variegated with yellow, with a mixture of red towards autumn. This is undoubtedly one of the most elegant variegated plants in cultivation, and like many others of its class a native of Japan. *L. japonica*, or *L. chinensis*, is a form of this species with more or less hairy leaves.

6. *L. flavosa*.—Stems and young leaves hairy. Leaves ovate-lanceolate, purplish below when young. Flowers pink and yellow, in pairs, very fragrant. Japan.

7. *L. cylindrum*.—An erect species with small ovate or obovate hairy leaves and hairy yellow small flowers in axillary pairs. There are varieties with white, yellow, crimson, and black berries. A native of Europe, introduced in some parts of this country. *L. Tatárica* is an allied species with rosy-pink flowers in the common form, and yellow or white in the varieties.

8. *L. fragrantissima*.—This species is desirable as an early-flowering plant. It puts forth its pure white highly odoriferous flowers in February before the leaves are developed. *L. Stándishii*, very near the preceding, has purple and white scented flowers. Both are natives of China.

Paraffin Oil.—*Les Mondes* informs us that M. Jorbery renders paraffin oil as thick as honey, by means of a vegetable powder (*Saponaria*), and thus prevents the liability of its causing fire, without, in any way, interfering with its properties, as it can be rendered fluid by the addition of a few drops of strong acetic acid. This is good news for people who employ it *inter alia*, for keeping frost out of small greenhouses.

## WORK FOR THE WEEK. PRIVATE GARDENS.

**Flower Garden.**—Spring flowers are now daily becoming so plentiful that herbaceous and shrubby borders are getting quite attractive; on lawns, too, are tufts of Crocuses, Snowdrops, Dog's-tooth Violets, and other favourite bulbous plants that annually spring up and unfold their beauties when once planted in such positions. They get cut down prematurely by the first turn of the scythe or lawn-mower, but the following year they spring up again numerically increased, and with greater vigour than before. Under the wide-spreading canopy of large deciduous trees a spring carpet of white, yellow, and blue, furnished by early blooming bulbs, is most desirable and pleasing, and in such a situation they thrive where not a vestige of Grass will grow. Only the commoner kinds, however, should be used in that manner, for the finer ones, if so treated, are apt to degenerate; hence the necessity of a good position for them, where they can retain their foliage until the bulbs are properly matured, when the foliage may be cut over, and the surface of the ground carpeted with annuals or other shallow-rooting plants. Lawns should be swept, rolled, and if necessary mowed. Where they are covered with moss it should be raked off, a top-dressing of finely sifted soil applied, and some Grass and white Clover seeds sown at the same time. The top-dressing should be equally spread, raked smoothly and level, and then well rolled. Should the lawn be thinly covered with grass, although free from moss, a top-dressing of good soil with some guano mixed with it, and also a sprinkling of Grass and Clover seed will greatly renovate the turf; before applying it, however, go over the surface with an iron-toothed rake, so that the old and new soils may the more readily unite; soot, salt, or guano applied alone in rainy weather is also productive of excellent results. If the edges of lawns or Grass walks be well rolled before trimming them, that operation can be more neatly and accurately done. Turling of lawns may still be performed, but the sooner such work is finished now the better will the Grass stand the summer's drought. In the absence of turf, seeds may be used, but in that case a long time elapses before a thick close carpet can be formed, and continuous attention in the way of mowing is requisite. Alterations in the flower garden or pleasure grounds may still be proceeded with. The planting of deciduous trees cannot, however, be too speedily finished now for a season; evergreens may be transplanted later. Coniferous trees, as a rule, transplant very well in the spring time. In planting, preserve the roots as entire as possible, and do not bury them more deeply than is necessary; stake such as require support. Instead of roughly filling in the soil, it should be well and carefully worked in amongst the roots with the hand, and a good soaking of water at planting time has also an excellent effect in settling the soil about the roots. Rose planting should now be proceeded with; indeed, where the trees are grown on their own roots, this is a good season for transplanting them. Roses in general may now be pruned. A thinning of the shoots is sufficient for strong growing kinds, whilst some of the dwarf and more compact sorts bear a severe shortening of the shoots with impunity. A good dressing of manure should now be forked into Rose beds or borders. Transplant spring-flowering plants as occasion requires, and dust some fresh air-slaked lime amongst them to keep off slugs. Transplant seedling Pansies, and pinch the tops out of old plants, to encourage the production of laterals and continuity of flowering. Transplant autumn-sown Mimuluses and annuals, such as Candytufts, Nemophila, and Eshscholtzia, where they are to bloom. Biennials, such as Rockets, Sweet Williams, Wallflowers, Hollyhocks, Canterbury Bells, Foxgloves, Auchsas, &c., may also be similarly treated. Annuals for early flowering may be sown in light soils and in warm situations; sow thinly, and thin out a little immediately after the seeds germinate. Remove last year's shoots, if any, from herbaceous plants, and give the borders in which they grow a good dressing of well-decayed manure. Overgrown specimens should be lifted, divided, and transplanted either permanently or in nursery lines, as may be most convenient. Where mulchings of leaves, straw, or litter were placed around the necks of plants of Pampas Grass, Tritomas, &c., remove them gradually. The protection given to Myrtles, Loquats, Clematises, and other all but hardy plants on walls, may now be partially, and, in many cases, wholly removed. Finish planting Box, Euonymus, Santolina, Japanese Honey-suckle, and Ivy edgings. If any of these are turned out of pots, shake the soil from their roots, and spread the latter well out; after such treatment they may remain stationary or nearly so for a few weeks, but when they begin to grow they will proceed with a vigour unknown to plants committed to the soil with matted roots. The golden variegated Thyme is now popular as an edging plant, and deservedly so, for it is quite hardy; old plants of it may now be lifted, divided, and transplanted permanently; any in pots subjected to an increased temperature will afford cuttings freely, and they

will root as readily as Verbenas. An edging formed by dividing old plants last autumn has now scarcely a plant in it alive, whereas one formed in the same way alongside of it last spring has withstood the winter unscathed. *Campanula carpatica*, *Stachys lanata*, *Cheiranthus Marshallii*, *Cerastium*, &c., make excellent edgings, and this is the right time for forming them.

**Greenhouse Plants.**—Remove some of the most backward *Cinerarias* to a north house, so as to preserve their lateness; water those that are in bloom freely, and occasionally with manure water; keep them free from insects by fumigation. Chinese *Primulas* required for seeding should not be burdened too much; therefore reduce the quantity of flowers on each plant to one or two trusses, according to the strength of the plants. Remove into a corner of some pit the finest *Cyclamens* for seeding purposes; half a dozen or so of flowers are sufficient on each plant, and there is no necessity for artificial assistance in fertilisation unless new colours are aimed at. Keep herbaceous *Calcularias* growing gently, by supplying them liberally with water and keeping them in a light and airy house and near the glass. Repot such show and fancy *Pelargoniums* as require it, and, if possible, place them on stages quite close to the glass in houses abundantly ventilated; if a little artificial heat be given at the same time a beneficial influence will soon be manifest in the green healthy foliage and stubby growth of the plants which is so productive of abundance of flowers. Violets that were bloomed in pots during the winter may now be transferred to a warm border. Give a little water to such Japanese Lilies as are beginning to grow. Hyacinths and Tulips should be kept as cool as possible and in light houses; they have come on so quickly this season that it is difficult to retain them late enough for some of our exhibitions. *Lachenalias* are now blooming pretty freely; keep them near the glass and treat them liberally. Repot young *Fuchsias*, pinch the points of the branches at the fourth or fifth joint, and keep the plants in the warmest part of the house. Some of the old plants may be shaken out of their present pots and repotted in others according to size in good open compost. In pruning the old plants, be rather sparing until they begin to grow. *Staticee* should be repotted and kept in the warmest part of the greenhouse; the old plants may be shaken out of last year's pots and repotted in smaller ones, for once growth begins in *Staticee* they must never suffer for want of pot-room. Save all seeds of *Solanum capsicastrum*; cut down the old plants, and save young shoots for cuttings. Repot, and remove for the same purpose the suckers of *Calla aethiopia*. Cut off the ends of the branches, and thin plants of *Veronica Andersoni*; then start them into growth. *Salvias* in pots, and rested during the winter, if now pruned, repotted, and kept in moderate heat, become fine flowering plants in a short time. *Kalosanthes coccinea* should now be repotted in a compost of good loam and some thoroughly decayed manure. Cut back *Bouvardias* that have done flowering, and use the young shoots for propagating. Cut back, repot, and start into growth some plants of the Lemon-scented *Verbena*. Turn out into frames young *Chrysanthemums*, and see that none suffer for want of potting. Repot and stake choice *Petunias*, and sow some seeds in light soil in gentle heat, for conservatory blooming; the surplus may be economised for bedding purposes. Train Tree *Mignonette*, and admit plenty of air to dwarf-growing plants in pots. *Mimuluses* of the finer varieties, as well as *Musk*, may be potted in two parts loam and one of decayed manure, with some sand; they soon grow and form nice flowering plants. Wire baskets containing the latter, and also others planted with *Mother of Thousands*, may now be made up either for the window or for suspending from the roof of the conservatory. Some Globe *Amaranths* may now be sown in moderate heat, and pricked off when the young plants appear. Balsams, Cockscombs and other *Celosias*, *Cinerarias* for autumn flowering, *Schizanthuses*, &c., may be treated in the same way.

**Ferns.**—The general potting of these should have been done last month; but, if the operation has been delayed until now, it ought to be at once accomplished. If the plants have begun to grow, they will be more liable to suffer from shifting than they otherwise would be; but with careful attention in the way of shading, maintaining an equable but gradually-increasing temperature, and supplying a moderate amount of moisture, both to root and top, little danger need be apprehended. Ferns whose fronds spring directly from the soil require a richer compost than such sorts as *Davallia canariensis*, whose rhizomes grow above ground. To the former give a mixture of equal parts of good fibrous peat and loam, with the addition of some leaf-mould, plenty of silver sand, and some small chips of fine sandstone. If the plants be required, however, for furnishing purposes, a little more loam and a little less peat will induce a hardier growth, and one better adapted for house-work than the luxuriant growth promoted by the first-named soil. Those with rhizomes above ground may be potted in fibrous peat and

a little leaf-mould, pegging the rhizomes down on the soil. Some of the Davallias, Polypodiums, Phymatodes, Pleopeltis, and others grow well on old stumps of tree Ferns, affixing themselves thereto like Orchids; if the stumps are in the vicinity of other Ferns, spores of different species are sure to vegetate in their crevices, more particularly those of Adiantums, Gymnogrammas, Aspleniums, and Pterises. Syringing Ferns is an operation requiring skill and care, for although some genera are partial to such treatment, others are particularly averse to it, more especially the Adiantums, Gymnogrammas, Cheilanthes, and other delicate and farinose kinds. Filmy Ferns are best grown in glass cases, or under handlights or bell-glasses, or a division of the Fernery may be specially set apart for their culture. Most of the small delicate species thrive well on blocks of decaying wood, pieces of the tree Fern stumps, or in pots; whilst for strong-growing kinds, like the Todeas, pot culture is the best and most convenient. For pot culture fibrous peat, chopped sphagnum, and some fine sandstone chips make a good compost, and for Todeas the surface may be mulched with live sphagnum. The smaller kinds of Ferns thrive well on little mounds composed of fibrous peat and sandstone chips, or on a block of wood embedded in turfy peat from which they can emerge and scramble over the wood. These Ferns like a steady moist atmosphere, but too much artificial heat is detrimental to them; in fact, a greenhouse temperature is almost sufficient for the whole of them. In watering let the water fall lightly upon the fronds; but in addition to these slight sprinklings, water must also be given to the roots, more especially during the growing season. Hanging baskets should now be replenished with Ferns and Selaginellas, and Wardian cases should be examined and refilled if necessary.

**Hardy Fruit Trees.**—Finish the pruning and nailing of fruit trees on walls as expeditiously as possible, and give the trees a thorough washing with the garden engine. The flower buds in the case of stone fruits are almost ready to burst; indeed those of Apricots, on warm walls, are beginning to open. Some kind of protection must therefore be afforded them without delay. Fruit trees and bushes may yet be planted, but the sooner the operation is finished now the better. Cuttings of Gooseberries may still be made, and inserted in nursery lines a foot apart, and from 4 to 6 inches asunder in the row; cuttings put in in autumn are, however, decidedly preferable to those inserted in spring. The cuttings should be 10 inches long, and divested of all buds except three or four at the top. No buds should be buried in the soil, nor be allowed to exist on the 3 inches of stem just above the ground. Scions for grafting should be taken off, if not already done, and "heeled" in until wanted for use. Make fresh plantations of Strawberries if necessary, remove all runners from old ones, fork over the soil between the rows, and incorporate with it some well-decayed manure at the same time. If a dressing of rough litter be applied between the rows after the ground has been forked over, it will serve as a mulching, and the rains will wash down nutriment from it to the roots, while the surface will form a clean resting-place for the forthcoming crop.

**Kitchen Garden.**—Make plantations of Jerusalem Artichokes in lines from 2 to 3 feet apart, in any odd corner of the garden. Plant Horseradish sets 15 inches deep, in thoroughly trenched ground, in rows 18 inches asunder. Plant the main crop of Potatoes. Autumn-sown Angelica should now be transplanted in rows 2 feet apart, in rather moist soil. Mint may be divided and transplanted alongside of the Angelica, in lines 15 inches apart. Seakale roots may be transplanted for next year's crop, and some seeds of it sown thickly in beds. Divide the roots of such plants as Hyssop, Chamomile, Pennyroyal, Sage, Savory, and Rue, and transplant them into fresh beds. Sow some Marrow Peas; a good plan is to plant four rows of Potatoes, then a row of Peas, and so on; this gives the Pea crop more light than it otherwise would have. Sow a full crop of Beans, and draw some earth to those that are above-ground. Sow some Leeks for transplanting; also some Parsnips in lines 20 inches apart, in deeply-trenched ground. Sow likewise some Cos Lettuces on a warm border, and plant out those that have been wintered in frames. Sow some round-leaved Spinach between rows of dwarf Peas or elsewhere; also early Horn Carrots at once, if the ground is in good order, and a main crop in the last fortnight of the month. Sow the main crop of Onions as soon as the ground is in good condition for its reception. If Parsley has not been already sown, some should be put in at once. Sow also some Asparagus seeds in drills 18 inches apart, but do not transplant last year's seedlings till next year. Gradually remove the protecting material from the necks of Globe Artichokes. Sow some Brussels Sprouts and other members of the Cabbage tribe for autumn use. Of Rocambole, Garlic, Chives, and Shallots, transplant cloves or offsets at once.

#### MARKET GARDENS.

Where the late snow-storm has killed newly-planted Lettuces, let the vacancies be made good without delay. Radishes should be sown

with or without a covering of litter; but some protection of that kind at this early period of the season greatly assists them. A large sowing of White Dutch Turnips may now be made broadcast on a warm piece of ground; those sown on beds should be covered and uncovered daily like Radishes. Finish transplanting autumn-sown Onions as soon as possible; ground on which Rhubarb, Parsnips, Asparagus, Savoys, or Brussels Sprouts have been growing may be devoted to them. Manure it well, trench it, level it with a rake, then trample it with the feet; after that roll it, and finally line it off and transplant. The Tripoli Onions are preferred to all others for drawing from the beds in spring, on account of their long white necks, while their hardness renders them suitable for autumn sowing. Sow the spring crop of Reading and Deptford Onions at once. Leeks should be sown in a frame heated with 18 inches deep of litter, and as they come up the sashes should be tilted up a little. Plants from this sowing are well suited for transplanting, as they come in earlier than those sown in the open air. Keep the sashes on frames, where Lettuces are only germinating, tilted up a little throughout the day; but shut them up at night. Expose completely autumn-sown ones, and transplant them in every available piece of ground. Where they have been wholly removed from amongst Carrots, the frames and sashes may also be taken away and used for Cucumbers, young Lettuces, Leeks, Tomatoes, Marjoram, or other plants requiring their assistance. Sow the main crop of Parsnips as speedily as possible—the hollow-crowned variety is the best. Plant also the main crop of Potatoes and Jerusalem Artichokes. Any Cabbages yet unplanted should be put in at once. Proceed with the planting of Seakale roots, as formerly directed: some recommend seedlings starved for the first twelve months in the seedbed, where they are sown thickly; but cuttings of roots are by far the best, and least troublesome. Dig and trench all spaces from which crops have been cleared. Plant out autumn-sown Parsley, about 6 or 8 inches apart from plant.

#### INCOMBUSTIBLE WOOD.

At a meeting of the Society of Arts, a paper was read by Mr. D. O. Macomber, on the desirability and process of rendering wood for building and other purposes incombustible. The lecturer dwelt at the outset on the great advantages possessed by wood over other building materials, such as stone or iron, even where the substitution of the latter was feasible, provided that that substance, naturally so inflammable, could be rendered so impervious to the action of heat as to prevent its bursting into flame when subjected to an excessively high temperature. There were, he said, very many means by which fire might be accidentally kindled, but to render it to any extent injurious it was essential that it should have a more or less free supply of atmospheric air. This air in ordinary seasoned wood penetrates the minute and innumerable sap-tubes with which all timber is pierced, and from which, by the process of drying, the liquid has been extracted. Thus, on the application of a strong heat, the dry wood is at once ready to burst into flame. Many methods, Mr. Macomber went on to say, had been hitherto invented by which the exterior, but only the exterior, of any woodwork might be for a time protected; but what was really and essentially wanted was some means of thoroughly permeating the wood with a liquid which should effectually protect it from the action of heat. Of course the carbonizing effect of fire could not be combated, but the object would be gained if the outbreak of flame could be avoided. This is precisely what Mr. Macomber proposes to effect. His plan—the details of which are somewhat too complicated for notice here—is to extract, by hydraulic pressure, steam, or other means, the sap from freshly-cut or "green" timber, replacing by chemical means the moisture expelled with a solution containing some substance or substances which, without producing any other material change in the character of the wood, shall render it for ever incombustible—that is to say, proof against all but the charring effects of heat. The precise nature of the solution to be used was not stated. Mr. Macomber has, he thinks, satisfactorily ascertained that it will by no means affect the colour of the wood, or the facility of cutting and fashioning it. The weight, lastly, will not be increased more than about two and a half per cent. Not only will the action of fire be resisted, but the rotting produced in ordinary wood by the boring of worms and other insects will be entirely kept off. The preparation, taken only superficially, has, as has been seen, a decided advantage over the silicious solutions formerly used to steep timber in, which have been found so injurious to the tools of the artificers engaged in working it. As the operation must be carried on while the wood is in its green or undried state, it follows as a matter of course that it must, in order to be of any use, be applied largely before exportation from Norway, Sweden, Canada, and other countries from which we obtain our large timber supplies. The estimated increase in the price of wood so treated is stated to be less than twenty per cent.

## NOTES OF THE WEEK.

— AMONG various interesting and well-grown subjects sent to Kensington the other day by Mr. Herbst, of the Kew Nurseries, was a batch of forced Lilies dwarfier than we have ever seen them before. To secure blooming plants of such a popular flower so dwarf as to be fitted for association with small subjects on greenhouse stages, and which may be readily placed in a case in the sitting-room, is a great point, and we hope Mr. Herbst will make these dwarf plants popular.

— MR. EDWARDS, superintendent of the Regent's Park for the last twenty years, has been presented with a testimonial of the value of nearly 100 guineas, by the officers and men employed in the park, as a mark of their esteem and respect, and for the kind way in which Mr. Edwards has discharged the duties of his office. Every man, however poor, and they are all at weekly wages, felt bound to give, and gave unasked, that which he could with propriety spare. Mr. Edwards is seventy-five years of age.

— ACTIVE preparations are now being made at Ghent for the Horticultural Exhibition which will be held there from the 30th of this month to the 6th of April. An area of about 5,000 square yards is being covered in with glass structures, which will be divided into three compartments, heated to different degrees of temperature. We are informed that M. le Bourgmeister, of Ghent, is arranging his rich collections of Palms, Ferns, &c., for exhibition in his great conservatory, which measures 292 feet in length, by 78 feet wide and 65 feet high. Visitors to the Horticultural Exhibition will, we believe, be free to inspect this fine collection.

— SOME years ago Lord Mayo offered a reward of £10,000 for a machine to clean and prepare Rhea fibre for the market. Mr. Greig, of Edinburgh, alone entered the lists, and his patent, which has been tried at the Saharumpore Botanical Garden, has proved so far hopeful that Government has awarded him £1,500. Rhea fibre is furnished by *Bemeria nivea*, the Rhea of Assam, a plant belonging to the Order of Netteworts. The beautiful fabric known in England as Grass-cloth, which rivals the best French cambric in softness and fineness of texture, is manufactured from the fibre obtained from the inner bark of this little shrub, which has long been cultivated both in China and India. Experiments made with the view of testing the strength of this fibre have proved it to possess nearly double the tenacity of Russian Hemp.

— AMORPHOPHALLUS RIVIERI is at present in bloom in the nurseries of Mr. Wimssett, Ashburnham Park, Chelsea. The spathe is of a brown colour, and the spadix, which is thick and fleshy and about 15 inches long, is of a darker brown even than the spathe, above which it rises several inches. The spathe is broadly campanulate, and beautifully undulated at the margin. Like other members of the singular tribe to which it belongs, it emits a disagreeable odour whilst in bloom, though not quite so bad as that of some of the others. The plant is of easy culture, requiring only warm greenhouse treatment and open spongy material to grow in. In the United States this remarkable Aroid is used for the ornamentation of the flower garden, to which its peculiar foliage renders it an acquisition.

— SOME choice Orchids and other plants, the property of Mr. Dixon, of Beverley, were sold the other day at Stevens' Angraecum sesquipedale, among others, fetched 14 guineas; *Cologyne cristata*, 13 guineas; *Odontoglossum Andersonianum*, 11 guineas; *Vanda Dennisoniana*, £8, and others from 2 to 5 guineas. The total amount realised for 346 lots was £130. Good bulbs of *Lilium auratum* sold by the same auctioneers fetched from 1s. to 2s. 6d. each; *L. Washingtonianum* from 3s. to 5s. each; *L. concolor angustifolium*, 2s. 6d. each; *L. californicum*, 4s. to 6s. 6d. each; *L. carnolicum*, 2s. 6d. to 3s. each; *L. tigrinum Fortunei*, 10d. each, and *L. longiflorum* from 4d. to 5d. each. Pinus seed fetched from 3s. to 5s. an ounce. The sale of some 591 lots brought altogether £359.

— MESSRS. TEUSCHEL & Co., of Colchester, who have imported plants of the Kaki or Chinese Date Plum, from Japan, have, we observe, instructed Messrs. Stevens to sell them by auction on Monday next. The Kaki is a native of both China and Japan, and is cultivated in India. The fruit when ripe is of a bright reddish-orange colour, about the size of an Apple, and has a yellow fleshy pulp, somewhat like that of a Plum. The Chinese eat these fruits both in a fresh and dried state. They are said to have an Apricot flavour, blended with that of the Medlar. They are the produce of a *Diospyros*, concerning the specific name of which some controversy has arisen. M. Carrière first called it *Diospyros Kaki*, then *D. costata*, a name under which it is figured in *Revue Horticole* for July 16th, 1871. M. Decaisne objects to both these names, and calls it *D. Schi-Tse*. It may possibly succeed against a south wall in the warmer parts of this country, or at least in an orchard house, and as upwards of a hundred trees of it are to be sold, the sale may be expected

to excite considerable interest. Some rare Lilies, a quantity of *Calochortus*, and the beautiful *Erythronium giganteum* are also to be sold on the same day.

— M. LÉON SISLEY, writing from Japan, on the 29th of last December, states that, notwithstanding the winter had just set in there with 3° or 4° of frost, the Camellias growing in the open air were beginning to open their buds.

— MESSRS. PROTHEROE & MORRIS, the well-known auctioneers and estate agents, of Leytonstone, have just started a new *Horticultural Register*, which is to be published on the first of every month. The register will contain a list of nurseries, market gardens, florist and seed businesses, to be let or sold; and to those who are desirous of renting or purchasing, an opportunity will be afforded of fully stating their requirements. Firms desirous of taking in a partner, and persons seeking a partnership, will in this way also be enabled readily to obtain the requisite information.

— WE have just received from Messrs. Capes & Dunn a catalogue of the Manley Hall collection of plants, all of which are to be sold by auction on the 7th, 8th, 9th, 10th, 15th, 16th, and 17th of next month. The catalogue contains 1,623 lots, consisting of some of the finest specimens of indoor plants in the kingdom, many of which are both new and rare. The first four days will be devoted to the sale of Orchids and a few Pitcher Plants; the last three days to miscellaneous stove and greenhouse plants.

— THE Mayor of Hyères (Var) has made over to the Society of Acclimatisation at Paris about fifteen acres of ground for the formation of a branch Garden of Acclimatisation, in connection with the Jardin in the Bois de Boulogne. The deed of conveyance gives the society sole possession of this property, free of all charge, for twenty-six years. The establishment of a branch in the mild climate of Hyères will doubtless be followed by important results, as the society will thus have an opportunity of experimenting with many tender subjects which will not endure the winter at Paris.

— IN the Winter Garden at Kew is an extremely handsome plant of *Aracaria Bidwillii*, about 26 feet in height; its branches cover a space of 21 feet in diameter, and its trunk measures over 2½ feet in circumference at a foot above the ground. It is planted out in one of the borders, where it grows freely, and last year bore 13 cones about 2½ feet from the top of the tree; ten of them are still on the plant, three having lately dropped off, owing to being decayed at the core. These cones are about 5 inches in diameter and 8 inches long, but as they take three years to come to maturity, those yet on the plant may become much larger. This specimen is said to be one of two introduced from Australia in 1842, the other plant being purchased by the late Duke of Devonshire for one hundred guineas. In its native country the seeds of this *Aracaria* afford an article of food for the natives.

— AN eminent Chancery barrister, who has been consulted on the legality of the propositions recently submitted by the council of the Royal Horticultural Society to the Royal Commissioners, has delivered his opinion, "that Clauses 3, 4, 6, 10, and 11 of the proposed agreement are beyond the powers of the council, even if they obtain the assent thereto of a majority of Fellows at a general meeting; and that, upon a bill filed on behalf of the Fellows and debenture holders, the Court of Chancery would restrain the council and the society from entering into or acting upon any such agreement." The Council, we understand, are still anxious to "resign a body," and new bye-laws, enabling them to do so, will, we hear, be submitted soon to the consideration of a general meeting of the society.

— SOME short time since we announced that Mr. Carmichael, late of Sandringham, had been appointed superintendent of the gardens at Hampton Court. It now appears that this announcement was premature. Mr. Carmichael had obtained the recommendation of his late Royal employer and other friends, and was accepted by the Board of Works, subject to the consent of the Civil Service Commissioners. That body were satisfied as to Mr. Carmichael's ability and testimonials, but refused to appoint him on the score of age—Mr. Carmichael, though in the prime of life, being a few years older than the assigned limit. Looking at Mr. Carmichael's status in the gardening world, however, we cannot but hope that some situation worthy of his abilities may speedily be found for him. Hampton Court is still vacant, and Her Majesty's Commissioners of Works will be ready, we understand, to consider applications for that situation from educated gardeners experienced in laying out grounds, in the management of men, and in keeping accounts. The limits of age are from 30 to 45, and the salary is £130 per annum, together with apartments in Hampton Court Palace. Persons desirous of becoming candidates for this appointment should make immediate application in writing, accompanied by testimonials, to the Secretary, Her Majesty's Office of Works, 12, Whitehall Place, S.W.

## SOCIETIES, EXHIBITIONS, &amp;C.

## ROYAL HORTICULTURAL SOCIETY.

(MARCH 5TH.)

PROMINENT among subjects exhibited on this occasion were several extremely fine collections of Cyclamens and Orchids, together with forced flowering plants, hardy spring flowers, Camellias, and Chinese Primulas.

**Cyclamens.**—These were staged in great numbers by Mr. Goddard, gardener to H. Little, Esq., Cambridge Villa, Twickenham, whose plants were in beautiful condition, the foliage being large, fleshy, and finely variegated, and the petals of the flowers, of which there were from one to twelve dozen on each plant, broad, blunt, and regularly reflexed. Their colours ranged from snowy-white to deep crimson, the gradations between these two extremes being rose, salmon, and other intermediate tints; but the white sorts seemed to be the most appreciated. Nor were Mr. Little's plants the only fine Cyclamens shown, for Mr. James, of Isleworth, furnished some excellent plants both in the competing classes and also for exhibition. From Mr. B. S. Williams also came a collection of Cyclamens, and Mr. Smith, nurseryman, Ealing, likewise contributed a group of young blooming plants furnished with remarkably fine flowers.

**Chinese Primroses.**—Among these, Waltham White, exhibited by Mr. Wm. Paul, stood in the first rank. Its flowers are of the purest white, individually large, and of good substance, produced in good-sized trusses, and the foliage is strong, robust, and fern-like. Of Princess Louise, white, tinged very faintly with pink, and Marquis of Lorne, a large crimson-flowered kind, several fine plants were exhibited by Mr. James, Isleworth. These two kinds have flowers exceptionally large and fine.

**Roses.**—Of these Messrs. Veitch and Sons exhibited a grand collection of small, well-flowered specimens, each plant bearing from half a dozen to two dozen flowers. The foliage, too, was in admirable condition. The following are the names of some of the kinds:—viz. (Hybrid Perpetuals), Princess Mary of Cambridge, Marie Ducher, Mme. Marie Girodte, Mme. Fillion, Mme. Victor Verdier, Mons. Boncenne, Maurice Bernardin, Victor Verdier, Marechal Vaillant, Jean Gonjon, Anna de Diesbach, Camille Bernardin, Anna Alexieff, Dr. Andry, Beauty of Waltham, Prince Eugene Beauharnais, Pierre Notting, Madlle Marie Rady, Exposition de Brie, Pitord; Moss Rose—Lanci; Hybrid Bourbon—Charles Lawson; Bourbon—Rev. H. Dombrain; Tea—Mme. Villermoz.

**Camellias.**—Of these, both in the form of plants in pots and cut flowers, there was a good supply. Six large well-flowered specimens in pots were contributed by Messrs. Veitch & Sons; they consisted of *Angustina superba*, *Fimbriata alba*, *Leon Lequay*, *Donkelaari*, *Teutonia alba*, and *Bononiama*. From Mr. W. Paul, of Waltham Cross, came a large group of extremely pretty well-flowered small plants. Mr. Paul also contributed a large collection of cut flowers; and the classes set apart for competition were well furnished by collections from Mr. George, Putney Heath, and Mr. Grant, Withington Hall, Conleton.

**Lilies of the Valley.**—Two boxes of as finely grown plants of these as it is possible to imagine—both flowers and foliage being abundant and excellent—came from Mr. Herbst, Kew Road Nurseries, Richmond. Mr. George, gardener to Miss Nicholson, Putney Heath, and Mr. James, also contributed excellent examples of this favourite Lily.

**Hardy Plants.**—These were almost wholly furnished by Mr. Ware, of Tottenham, whose collection contained many pretty little plants, prominent among which were *Iris tuberosa* and *reticulata*; *Primula farinosa*, *denticulata*, *altaica*, *japonica*, *cortusoides*, *amena*, and the beautiful *P. verticillata*; *Rhodeas*; *Narcissi*; *Scilla bifolia* and *sibirica*; *Triteleia uniflora*; *Anemone blanda*; *Bulbocodium vernum*; the *Crimean Snowdrop*; *Funkias*, &c. From Mr. Dean, of Ealing, came two exceedingly handsome quite new hardy Primroses of free-flowering habit; both received first-class certificates.

**Orchids.**—These as usual formed the most important part of the exhibition. Messrs. Veitch had, amongst others, a grand plant of *Dendrobium Wardianum* bearing twenty-seven flowers, and for which a cultural commendation was awarded; also *D. thyrsiflorum* with densely-flowered spikes, *D. primuminum*, a fine basket Orchid, the pretty blue *Vanda carnulescens*, *V. snavis*, and the singular yet handsome *V. Catheartii*. Amongst *Odontoglossums* the same exhibitors showed lovely examples of *O. Alexandrae*, especially one called *O. A. maculatum*, a curiously spotted kind; likewise *O. nebulosum*, and *O. n. pardinum*, a dark-brown spotted sort, a finely-flowered specimen of *O. Andersonianum*, and several other fine Orchids; associated

with these were Palms, *Amaryllises*, &c., and a dark-leaved variety of New Zealand Flax, called *Phormium atropurpureum*. In a collection from Mr. B. S. Williams were some good varieties of *Lycaste Skinneri*, *Trichophila snavis*, nice specimens of *Cypripedium Warneri* and *villosum*, well-bloomed plants of *Vanda insignis* and *Phalaenopsis grandiflora*, and several fine examples of *Odontoglossums*, such as *Alexandrae*, *gloriosum*, *Rossii*, and *cordatum*. Besides these, there were, moreover, a plant of the small-flowered *Ornithidium coccineum*, *Dendrochilum glumaceum*, and others. These were effectively backed up by Palms, such as *Cocos Willisii*, *Thrinax elegans*, and *Corypha australis*; *Dracenas*, a nice plant of the charming *Tillandsia Lindenii*, and a grand specimen of *Imantophyllum mimium*, bearing half-a-dozen immense heads of flower. In a group of Orchids shown by Mr. Wm. Bull were plants of *Odontoglossum Pescatorei*, well furnished with flowers, and others of *O. gloriosum*, *lateo-purpureum*, and *triumphans*, all in first-rate condition; also *Lycaste Skinneri*, *Dendrobium nobile*, and others. Amongst miscellaneous plants from the same exhibitor, and which were intermingled with the Orchids, were examples of *Eucephalartos villosus expansus*, and *E. Cycadifolius compactus*, both fine plants; Palms, *Dracenas*, *Marantas*, &c., and *Amorphophallus Rivieri*, an Aracaceous plant, whose singular inflorescence seemed to excite much interest. A grand collection of Orchids was also contributed by Messrs. Rollisson & Sons, of Tooting, in which were some good plants of *Dendrobium nobile*, *pulcherrimum*, and *Wardianum*; a fine example of *Saccolabium giganteum* and of *Dendrochilum glumaceum*; and of *Odontoglossums*, good plants were contributed of *O. nebulosum* and *Andersonianum*. In the same group were likewise plants of *Oncidium leucochilum*, *Vanda snavis*, *Phalaenopsis Schilleriana*, and a few fine *Cypripediums*. From Mr. W. Denning, gardener to Lord Londesborough, at Sarbiton, came a grand collection of Orchids; among which were several fine forms of *Cattleya*, a few good *Odontoglossums*, particularly *Alexandrae* and *Andersonianum*, and a very fine example of *Cymbidium eburneum*. The same group contained, moreover, a plant of *Bolbophyllum siamense*, a pretty little free-blooming brownish-yellow flowered Orchid, *Epidendrum paniculatum*, some fine *Dendrobiums*, and a grand plant of *Coclogyne cristata Lemoniana*. A noble group of these valuable and popular plants was also furnished by Mr. C. May, gardener to J. S. Pockett, Esq., Muswell Hill; it included, amongst others, some fine *Cattleyas*, *Lycastes*, *Cypripediums*, *Oncidiums*, *Odontoglossums*, a good plant of *Lælia anceps*, an excellent example of *Dendrobium crassinode*, one of *Masdevallia tovarensis*, and several others. Of *Dendrochilum glumaceum*, a very fine specimen was furnished by Mr. Lawrence, Farnham Castle, for which a cultural commendation was awarded. Of *Dendrobium aggregatum*, Mr. Croucher exhibited a most profusely-bloomed plant growing on a block.

**Miscellaneous Subjects.**—Some exceedingly well-grown and bloomed Persian Lilacs in pots were shown by Mr. Herbst, of Richmond. Forced plants of *Astilbes* and *Deutzias* were also contributed by the same exhibitor, who likewise showed Ferns, Palms, Azaleas, &c. From Mr. George, Putney Heath, came several Ghent Azaleas, *Rhododendrons*, and *Andromedas* in flower.

**Fruit and Vegetables.**—Several bunches of last year's Grapes were exhibited in an excellent state of preservation, the berries being large and quite plump, and the bloom untarnished; they consisted of the Black Alicanto and Lady Downes, and were shown by Mr. T. Bannerman, Blithfield; by Mr. Sage, Ashridge Park; and by Mr. Parsons, Danesbury. From Mr. Dancer, of Little Sutton, came three dishes of Apples, large, firm, and excellent in quality; they were Northern Greening, *Reinette de Caux*, and *Dumelow's Seedling* or *Wellington*. A collection of vegetables grown at Naples was exhibited by Mr. C. Picarillo, of 43, Wigmore Street; they comprised Spring Onions, large and good, Naples new Salad and Cabbage Lettuces, with solid heads, *Endive*, *Early Peas*, a large Turnip-like white Radish of excellent flavour, two kinds of Broccoli, one a purple and the other a white kind, with large, compact heads, specimens of the tuberous-rooted *Fennel*, *Lemons*, and one or two other subjects of less importance.

**First-class Certificates.**—These were awarded to the following, viz. :—

To *Odontoglossum nebulosum*, var. *pardinum* (Veitch), a variety with flowers distinctly spotted with very dark-brown blotches.

To *Lælia* sp. (Veitch), a beautiful kind from Brazil, with flowers of a deep-orange colour.

To *Odontoglossum* sp. (May), a handsome sort with large showy yellow and brown flowers.

To *Asplenium longissimum* (Veitch), a species with comparatively narrow fronds, which are however 3 feet long, making it an admirable Fern for basket-work.

To *Agave Kerchovii* (Croucher), a medium-sized species with long narrow leaves sharply pointed; spines hooked a little, those on one side

being inclined towards the point of the leaf; those on the opposite side towards the base.

To *Agave Baxterii* (Croucher), a nice stubby medium-sized kind.

To *Agave perbella* (Croucher & Wilson Saunders), a medium-sized kind with formidable-hooked spines.

To *Primula vulgaris*, var. *auriculiflora* (Dean), a charming variety, the flowers of which are of a rich very dark velvety-crimson, almost inclining to black, in which is set a large yellow eye.

To *Primula Violet Gem* (Dean), another very valuable Primrose, which bears a profusion of exquisitely pretty blooms of a pleasing violet-crimson colour.

### YOUNG GARDENERS' INSTITUTION. ROYAL EXOTIC NURSERIES, CHELSEA.

Messrs. VEITCH & SONS, we are glad to learn, have formed an institution having for its object the accommodation and comfort of the young men employed in their establishment. Close to their nurseries they have leased a large and excellent house, the rooms in which are large and lofty and fitted it up to accommodate at least thirty men. One of the largest of the rooms is used as a dining-room, another as a library and news-room, a third as a smoking-room, and those on the upper floors are used as bedrooms. Kitchens, lavatories, and offices occupy the basement. On the south and east sides of this house is a large field, a portion of which is to be fenced in and converted into a suitable recreation ground for the young gardeners; indeed, everything that can in any way tend to their comfort has been considered, and no expense has been saved to procure for them homely and country-like privileges, a boon which young men unaccustomed to town life cannot fail to appreciate.

The President of this Institution is Mr. H. J. Veitch; the Vice-President, Mr. A. Veitch; and the General Committee consists of Messrs. Bause, Canham, Court, Davidson, Davis, Dominy, Heale, May, Seden, Simmonds, Sinclair, Taylor, West, and Wilkins; Mr. P. Veitch is Secretary, and Mr. Manning Accountant. The advantages that belong to this Institution are as follows:—1. Messrs. Veitch will buy all articles of food at the lowest wholesale prices, and supply the young men with breakfast, dinner, and tea, at the lowest cost price, thus giving them all the advantages of better food at less expense than the young men could procure it elsewhere. 2. Each man is provided with a separate bed. 3. A library, consisting of botanical, scientific, and religious works, will be open for their use. Various daily newspapers and all the leading botanical periodicals will be at their disposal. Chess and draughts also provided. 4. There is a good smoking room. 5. Lectures of an interesting and instructive character will be delivered periodically. To include chemistry, botany, garden architecture, the microscope, &c., &c. 6. The house is fitted up with the view of giving home comforts, and arranged so that the young men may spend their evenings in well-lighted, warm rooms, without any undue interference with their liberty. 7. Attached to the Institute there is a recreation ground, where quoits, bowls, and other amusements may be enjoyed.

The following rules and scale of charges have been decided upon by the General Committee, who will act with Messrs. Veitch in endeavouring to secure the comfort of the young men who may join the Institution; and the General Committee will likewise audit the accounts every month. 1. The house will be closed at eleven p.m. every night, excepting on Saturdays, when it will remain open till twelve o'clock. 2. Smoking allowed in the smoking room only. 3. No books to be removed from the Library. 4. No strangers to be admitted to the Library. 5. Every young man on leaving the Institution for a situation to sign his name in the book kept for that purpose.

The scale of charges is arranged so that young men may adopt one of two plans. To those who wish to pay a weekly sum it is proposed to charge 11s. per week, or 1s. 7d. per day, for which lodging, breakfast, meat dinner, and tea will be provided; but if a dinner of bread and cheese is preferred instead of meat, then the weekly charge would be 8s. 8d., and the daily charge 1s. 3d. If, on the other hand, the young men desire to pay for the different meals separately, the following is the scale of charges: For a single breakfast or tea, 1d. (bread and butter, tea, coffee, or cocoa); dinner, 8d. (meat, vegetable and bread); ditto, 4d. (bread and cheese); supper, 1½d. (slice of bread and cheese); beer, per glass, 1d.; tea and coffee, per cup (when extra to meals), 1d. These prices have been fixed at a meeting of the Messrs. Veitch and their foremen, and are liable to alteration and reduction where possible. Messrs. Veitch wish it to be distinctly understood that they have no intention of deriving any profit from the establishment of this Institution, but on the contrary they are willing to contribute towards the cost of the house, with the view of increasing the comforts of young men who may come to their nursery.

### MANCHESTER LITERARY AND PHILOSOPHICAL SOCIETY.

At a recent meeting of this Society, Mr. Joseph Sidebotham read a paper "On the Destruction of the Rarer Species of British Ferns," the object in view being to protest strongly against such destruction, and, if possible, to put a stop to it. He mentioned four districts in Lancashire, Derbyshire, Westmoreland, and Wales, and gave lists of Ferns which he had found abundantly in them twenty-five years ago, all of which have now entirely disappeared, or have become exceedingly rare. Since Fern collecting became a sort of fashion a few years ago, a class of people has sprung up who gain a livelihood by collecting and selling Fern roots to tourists; these are exposed for sale in the markets during the summer season, and it is pitiable to see cartloads of them torn from their native rocks and glens, and to think that not one root in a hundred will grow when carried away and planted on rockwork; and the few plants that do survive are but miserable representatives of their respective species. There are laws to protect the small birds from being exterminated, but none can be framed to protect our Ferns and wild flowers. The only suggestions the writer could make to preserve them was to appeal to tourists on no account to purchase roots of Ferns from these dealers, and not to dig up rare specimens when they find them, but content themselves with the fronds. He then enumerated the various native species of Ferns, and showed how few of them were suitable for cultivation in ordinary gardens and rockeries, and that for such a purpose the common species were really more suited in every way than the rarer, being handsomer and more easily grown. He also strongly advocated the growth of varieties from spores, and spoke of the pleasure he had experienced in examining the extensive collection of those raised by Mr. Lowe, of Highfields, near Nottingham. Mr. Hurst mentioned that the Madeira *Dicksonia enclita* had been eradicated from its sole Spanish habitat, near Algeiras, by collectors.

### COVENT GARDEN MARKET.

MARCH 7TH.

**Flowers.**—There is now a good supply of these, both cut and in pots; border plants may also now be had in abundance. Bouquet flowers consist chiefly of *Camellias*, *Azaleas*, *Cinerarias*, *Deutzias*, *Lily of the Valley*, *Acacias*, *Hyanthids*, *Tulips*, *Narcissi*, *Violets*, *Astilbe* (*Spiraea japonica*), *Cyclamens*, *Chinese Primroses*, *scarlet Pelargoniums*, *Cytisuses*, *Mignonette*, and *Rosebuds*. For bouquet making white flowers are chiefly in demand, but the intense blue of the *Cineraria* and the brilliant colour of the *scarlet Pelargonium* seem also to be favourites for making striking contrasts.

**Fruit and Vegetables.**—Apples and Pears are now almost entirely confined to those of foreign growth, but they are not keeping well. Grapes are good, and equal to the demand; and of Strawberries there is a moderate supply. Amongst vegetables there are some fine Carrots, and excellent salading; the commoner vegetables, too, are of first-rate quality. From Paris we have some fine Asparagus; and English-grown produce is also now fast improving. Forced vegetables are still good and plentiful, and Rhubarb is now obtained in limited quantities from the open air.

**Prices of Fruits.**—Apples, per half sieve, 3s. to 5s.; Chestnuts, bushel, 12s. to 20s.; Colts, per lb., 2s. 6d.; Grapes, hothouse, per lb., 4s. to 10s.; Lemons, per 100, 6s. to 10s.; Oranges, per 100, 4s. to 10s.; Pears, kitchen, per doz., 3s. to 6s.; dessert, per doz., 8s. to 12s.; Pine-Apples, per lb., 6s. to 10s.; Strawberries, per oz., 1s. to 2s.; Walnuts, per bushel, 15s. to 30s.; ditto, per 100, 2s. to 2s. 6d.

**Prices of Vegetables.**—Artichokes, per doz., 3s. to 6s.; Asparagus, per 100, 5s. to 10s.; Beans, Kidney, per 100, 2s. to 3s.; Beet, Red, per doz., 1s. to 3s.; Broccoli, per bundle, 9d. to 1s. 6d.; Cabbage, per doz., 1s. to 1s. 6d.; Carrots, per bunch, 6d.; Cauliflower, per doz., 2s. to 6s.; Celery, per bundle, 1s. 6d. to 2s.; Coleworts, per doz. bunches, 2s. 6d. to 4s.; Cucumbers, each, 2s. to 4s.; Endive, per doz., 2s.; Fennel, per bunch, 3d.; Garlic, per lb., 6d.; Herbs, per bunch, 3d.; Horseradish, per bundle, 3s. to 4s.; Leeks, per bunch, 2d.; Lettuces, per doz., 1s. to 2s.; Mushrooms, per pottle, 2s.; Mustard and Cress, per punnet, 2d.; Onions, per bushel, 3s. to 6s.; pickling, per quart, 6d.; Parsley, per doz. bunches, 4s.; Parsnips, per doz., 9d. to 1s.; Peas, per quart, 4s. to 8s.; Potatoes, per bushel, 4s. to 7s.; Radishes, per doz. bunches, 1s.; Rhubarb, per bundle, 1s. to 2s.; Salsafy, do., 1s.; Savoy, per doz., 2s. to 3s.; Scorzonera, per bundle, 1s.; Seakale, per basket, 1s. to 2s.; Shallots, per lb., 3d.; Spinach, per bushel, 3s. 6d. to 5s.; Turnips, per bunch, 3d.

**How to Preserve Fungi.**—It is sometimes desirable to preserve specimens of Fungi for future or more convenient examination. For such purpose the following mixture has been recommended: sulphuric acid, 2 pints; water, 8 pints; mix and add creosote, 1 pint. Bottle the Fungi in this and cork tightly. It is said to preserve them perfectly, without change of colour. Fungi may be preserved by drying, by bedding them in silver sand, gills upward, in tin boxes, and placing them in a slow oven for two or three hours. [Of this mode of preserving Fungi, we have had no experience. They may be very well preserved in spirit if required, or good bye as to the "colour," the preservation of this is, however, generally quite unnecessary.]

**The Indigo Trade.**—In 1870 the declared value of indigo imported was £2,721,208; in 1871, £2,932,238; and last year, £2,178,967.

## THE GARDEN.

—o—o—o—  
 "This is an art  
 Which does mend nature: change it rather: but  
 THE ART ITSELF IS NATURE."—Shakespeare.  
 —o—o—o—

### EARLY-FLOWERING SHRUBS AND TREES.

WHEN they come to be reckoned up, how large is the number of shrubs and small trees which we possess that produce gay, or at all events pleasing flowers in the earliest days of spring! Not half the use has yet been made of them that might be; the Evergreens have had it almost all their own way, as if there were nothing besides, and every one, no doubt, is glad to see the Evergreens shining, as they do, even in the snow of winter; but even they would look the better were early blooming deciduous shrubs intermingled with them deliberately and judiciously. By the exercise of a little skill in planting, the presence of the deciduous shrubs would interfere not in the least, and as soon as in bloom, the Evergreens would receive new beauty from the companionship, at the same time that in reciprocity of good service they helped to bring out the merits of what was leafless. We say "companionship" rather than contrast, for, depend upon it, the *beau-ideal* of horticulture, like that of well-ordered society, comes a vast deal more surely and readily of natural harmonies than of contrasts, let the individual merits of the contrasted things be ever so high; and what we have most energetically to consider is, not how things will best antagonise, but in what way they can be made most exquisitely and unaffectedly to blend. Two, or even three classes of the early-flowering arborescent plants may be established, but for our present purpose it is unnecessary to speak of any but the first, excepting in simple mention of the principal names. Possibly even the list of those we omit may have its value, since until some one points it out, even the most ordinary fact now and then eludes our notice. The hardest thing in the world to see most plainly is very often that which lies at our feet. The early-flowering shrubs, then, which do not belong to the section we purpose speaking of, are the self-excluded, through being evergreen as well, the Laurustinus to wit, the Garrya elliptica, the common Mahonia, the Spurge Laurel, the early crimson Rhododendron, the Erica carnea and its varieties (Mediterranea, &c.), the early blooming varieties (or, perhaps, they are only individuals) of the common Furze, and a little later in the season the Cherry Laurel. These plants are all intrinsically so good in their flowers that they ought to appear abundantly in every spacious pleasure-ground—the Spurge Laurel, if not showy, because of its delicious evening perfume, and the Garrya as the best thing nature ever devised for table epergnes. There is no occasion, however, to dwell upon them, since the greater portion are nearly universal, and need no eulogy, speaking, as the ladies do, for themselves. Nor is there any necessity for more than the bare mention of those charming and mostly old-fashioned things (equally meritorious, if we are sensible enough to take them *per se*), which present their flowers in company with the opening foliage. How beautiful in this department are the Pyrus, or more properly the Cydonia japonica; the Canadian Amelanchier, which seems a snow-flower caught *in transitu*, and changed to petals; the Larch, with that inimitable blending of tenderest green in little sheaves, and infant cones of loveliest pink; and though last, not least, the Apple tree, the Garland Crab (Pyrus coronaria), the wild Cherry, and several others belonging to the Pomiferae and the Drupiferae, those two capital families which seem at a loss whether to prefer poetry in the way of bloom, or substantial prose in the shape of fruit. Not last, after all, for we have skipped that every man's treasure—the Ribes sanguineum. Many who read these lines will remember with ourselves how horticulture clapped its hands when the Ribes became properly known, and its hardiness and easiness of multiplication were established. North-west America may have many more admirable contributions awaiting our gardens, but to beat the Ribes sanguineum will be hard. It may not be amiss to invite attention, while the plant is

before us, to the very curious phenomena observable in the flowers when double. Ordinarily, when flowers become double, the stamens either disappear entirely, or they hold only the uncomfortable half-and-half kind of existence so conspicuous in the double Snowdrop. Here, however, in the Ribes sanguineum, everything is multiplied and everything is perfect! Mark too, young botanists, for these particulars all have their practical value, how very beautifully the transition is shown in the Ribes sanguineum, from the ferules which form the outer layers of the leaf-buds upwards into the perfect leaves themselves. A florist and botanist can hardly help being allured into the byeways, sincere as may be his intention when he starts upon his journey, to keep to the highway, and thus have we got a little astray, but it is precisely the same class of travellers who can recover themselves most readily; they, of all others, know least of the tragic "*sed revocare gradum*." So looking to the deciduous early spring-flowering shrubs and trees, let us remark what a pity it is that the Cornelian Cherry (Cornus mas) is not more frequent. While everything is still bare of foliage, its slender twigs are densely clothed with knots of golden yellow, just about the same size as the flower-knots of the Elm, which are themselves no slight ornament to the tree as soon as the anthers have become protruded, giving it, when the sun shines, a shade of purple. Of the same bright yellow are the flower clusters of the Hamamelis, a tree very seldom met with, but eminently deserving, and of the fitness of which for our shrubberies there can be no question, since it endures the severe winters of New Brunswick. The Paulownia, unhappily, is too tender for the midland and northern counties of England; but what can be more splendid than the display it makes in April, in the south, pouring out grand violet-blue flowers fashioned like those of a Foxglove or a Gesnera, and aloft among the branches. It is from the same fertile country which was the birthplace of the Paulownia that England originally received that sweet and most dainty thing, the Japanese Chimonanthus fragrans, peer of the Mezeron in its fragrance, and commencing to bloom in February. The Mezeron has the advantage of it in point of colour, and is excellent, as every one knows, as a little standard; but there is a delicacy about the Chimonanthus, although relatively much less hardy, which enables it to hold its own anywhere; and, for minute examination, the amber and chocolate of the blossom are unique. Need we speak of the Almond, the Plum, the Sloe—one of the whitest flowers in nature—or of the Peach, or of the Apricot? Though the rude gusts that toss their blossoms to the Primrose render it hazardous to depend upon them as ornamental trees, there is always the chance of fine weather while their flowers are out, and the average of seasons is pretty sure to be not unfavourable. What beautiful plants, again, are the Forsythia viridissima and suspensa! Like the winter-flowering Jasmine (Jasminum nudiflorum), they may be everybody's, and against a wall become perfect sheets of brilliant yellow, excelling everything except the Laburnum, that in this particular colour is the enrichment of a later season. The Almond has a rival in the Judas tree (Cercis siliquastrum), another of the too-seldom-planted ones, though so splendid in its profusion of rosy flowers, shaped like those of the Furze, and springing from the naked old wood. We have seen this tree, when not large, not less completely enveloped in blossom than are the twigs of the Mezeron. Finally, there are members of the Amentiferae, that confer surprising beauty on the pleasure-ground when carefully placed; not to mention the familiar Sallows, loaded with large yellow catkins, and ensuring that pleasant sound, the hum of early bees; and not to mention the Hazel and the Filbert, dressed all over with these elegant pendants, that give their "touch of beauty" even to the hedgerow-nuts; there are the Poplars, in several kinds, and the Alders, in at least two or three. While the trees are comparatively young, the catkins of these last are exceedingly conspicuous. Everyone who has learned to love trees loves the catkin-bearers, and none that grow surpass the Alders in power of wooing towards the amiable pastime, to indulge in which, moreover, is a positive benefit to mankind, since demand for handsome trees implies demand for good tree-providers, and good tree-providers have to think steadily before they act.

## NOTES OF THE WEEK.

— Our able correspondent, Mr. George Gordon, is at work preparing a new edition of his excellent book, the "Pinetum."

— In Mr. Wrigley's magnificent collection of Orchids, at Bury, Lancashire, amongst other things at present deserving notice are nine finely-flowered plants of the beautiful "drawing-room Orchid," *Lycaste Skinneri*. These plants are by no means large, yet they have produced a total of 122 blooms on fourteen flowering bulbs.

— A Potato grower at Fontenoy considers that he has found a remedy for the Potato disease. At planting time he surrounds each Potato with a small quantity of waste tan, which is easily obtained, and of small general value. For three years he has done this with entire success, his Potato crop being now perfectly sound, though in former years, in the same field, it was diseased.

— There are at present in flower in the nurseries at Coombe Wood several beds of the beautiful new *Rhododendron*, Early Gem. This pretty little *Rhododendron* is a hybrid between *R. precox* and *R. davuricum atro-virens*; its habit is dwarf and compact, and the blooms, which are large and of a rosy purple colour, are produced in great profusion from towards the end of January throughout February and March. It is admirably suited for forcing purposes, as, on account of its natural tendency to bloom early, it does not require much excitement to induce it to develop its flowers.

— We understand that at a meeting of the Veitch Memorial Trustees, held the other day, it was resolved "That the Veitch Memorial prize be offered triennially, commencing with the present year; and that until the fund reaches the amount of £1000, the interest accruing in the two intervening years be added thereto." It was also resolved "That steps be taken to procure designs for a Veitch Memorial Medal, with the view of having the same executed, for use, if possible, at the forthcoming show of the Royal Horticultural Society at Bath," it being an instruction to the trustees that an inexpensive medal should accompany the money prizes distributed.

— We learn from the *Journal of Botany* that Dr. Ernst, of Caracas, has been named by the Government of Venezuela to fill the chair of botany in the University of Caracas, where natural history has hitherto never been taught. He is likewise commissioned with the foundation and management of a small botanic garden and its corresponding botanical museum. For the garden he will have the two large yards of the University building, both of which are over 1,500 square yards in area, which will give about 930 square yards available ground for planting.

— The town of Leamington has just lost a good friend by the death of Mrs. Willes, of Newbold Conyn, a property which the family has possessed since the time of Henry VIII. The late Mr. Willes presented to Leamington the Jephson Gardens, which he laid out, giving up land worth nearly £30,000 for the benefit of the inhabitants. He also presented sites for several churches, and to him the town owes the combination of squares, terraces, streets, and gardens, which extend from the canal, near St. Mary's Church, to Beauchamp-square and the Newbold Hills. He and Mrs. Willes also reserved several other valuable plots to be kept open for ever.

— At a meeting of the subscribers of the Royal National Tulip Society, held at Manchester after the annual show last year, it was unanimously resolved that the exhibition for 1873 should be held in Birmingham. In accordance with this resolution, the first meeting of this society for 1873 will be held at 96, High-street, Birmingham, on Saturday evening next, at six o'clock. All lovers of the Tulip will be pleased to learn that the prospect of success this year will bear a favourable comparison with that of any former period. Every effort should be made by growers and their friends to contribute to the funds of this society, to ensure a success worthy of its patronage and support. Subscribers and others are requested to send in their names, before the day of meeting, to Mr. James P. Sharp, Rose Cottage, Nechells-place, Birmingham.

— An important sale of Orchids and other plants belonging to Messrs. Backhouse, of York, took place at Stevens', last week. It consisted of both established and newly imported plants, foremost among the latter being the rare and beautiful *Oncidium tigrinum*, a description of which will be found in another page. A grand mass of this, consisting of upwards of thirty "bulbs," in splendid condition, fetched no less than £20, and smaller plants of the same realised from £3 10s. to £12. An extra strong flowering plant of *Oncidium macranthum* was sold for £9, and other good plants of the same *Oncid* fetched from £3 12s. 6d. to £7 10s.; imported plants of *O. Barkeri* realised from 3 guineas to £5. Of *Odontoglossum Bluntii*, some wonderfully fine plants were disposed of, one of which fetched £7, another £6, and several 5 guineas each. Plants in flower of the true *Odontoglossum roseum* realised from £4 10s. to £5 5s. respectively; whilst a strong plant of *O. Reichenheimii* fetched £5 10s., another £3 7s. 6d., and one of the true *O. Rossi majus*, with thirty-

five bulbs and seven shoots, £5 15s. A very fine variety of *O. Inscayi*, with high-coloured flowers and broad, heavily-spotted sepals and petals, realised £5, and lesser examples of the same *Odontoglossum* fetched from £3 3s. to £4 10s.; a fine mass of *O. citrosimum* fetched £3 10s. A strong plant of *Cattleya Mendelii* fetched £10; masses of *C. citrina*, with 150 bulbs, realised £7 10s.; another, with 100 bulbs, £7 7s.; a fine variety of *Disa grandiflora* fetched £1. *Trichopilia fragrans* realised from £3 7s. 6d. to £4 15s. A fine specimen of the pretty *Adiantum Farleyense*, with thirty fronds, fetched £10. The proceeds of the whole sale, which consisted of 351 lots, amounted to £933.

— We are glad to announce that Mr. J. C. Mansel-Pleydell's "Flora of Dorsetshire" is in the press.

— The Halifax Floral and Horticultural Society will hold a grand spring exhibition on Whit Monday and Tuesday, in the grounds at Craven Lodge, Halifax. The schedule of prizes is now being distributed.

— We understand that Mr. Bull intends exhibiting at the spring show of the Royal Horticultural Society, to be held on Wednesday and Thursday next, a large collection of plants, including several new kinds of *Eucephalartos*, *Cycas*, *Macrozamia* and *Zamia*.

— In a recent number of the *Times* we read of the decease, on February 21, at Naples, of M. Max Nisson, aged fifty-four. M. Nisson was a great lover of plants, and was a constant attendant at the International Horticultural Congresses. He was one of our foreign guests in 1866, and paid a visit to this country last year.

— The new strip of garden belonging to the Zoological Society on the north side of the Regent's Canal, is now being put into order. The bridge over the canal is already finished, and the new lodge opposite Primrose Hill only wants the entrance gates and turnstiles to make it complete. We understand that it will be open to the public on Easter Monday.

— The Islington guardians have been lately making use of a machine for peeling the Potatoes used by the inmates, and it is said to be so very useful and economical that 9s. a day is saved to the rates by its use. The guardians of the Holborn Union, on these facts being brought to their notice, have ordered a similar machine to be supplied to each of their three workhouses.

— In reference to the forthcoming exhibition at Bath of the Royal Horticultural Society, it may be mentioned that the local committee are actively at work. The schedule of prizes will shortly be published, and will be found to be far in excess of that of any previous exhibition of the society. Applications will be made through influential channels to induce the Prince and Princess of Wales to inaugurate the opening on the 21th of June, and there is every probability of success.

— Mr. H. C. Watson intends to print a selection from the materials collected in years past to show the distribution of British plants through the different counties, and has issued a circular to English botanists requesting them to send any facts additional to those recorded in the "Compendium of the Cybele Britannica" and its Supplement, so as to render the enumeration as complete as possible. We cordially second his appeal, and congratulate British botanists on the prospect of so useful a book.

— The temperature of February this year (says *Nature*) has shown some very curious peculiarities, and a marked contrast to that of the earlier part of the winter, as may be seen from Mr. Glaisher's tables of observations at Blackheath. While, during the whole of the three preceding months, there were only twelve frosty nights, with the temperature of the twenty-four hours almost uniformly above the average of the last fifty years, the thermometer fell below the freezing point in eighteen nights in February, and the temperature was below the average on every day except two, the total depression on the month being 4° 3 Fahr. The records of very few winters will show so high a minimum as 25° 0 Fahr., the lowest temperature of the past winter at Blackheath, which occurred on February 24 and 25, the thermometer falling below 30° 0 on only seventeen nights during the whole winter. Since March 2 the temperature has been again uniformly above the mean.

— We are much pleased to notice the introduction of a new yellow-flowered *Columbine* (*Aquilegia leptocera lutea*), which is thus described in the catalogue of Messrs. Backhouse and Son, York, just received by us:—"This is unquestionably one of the finest perennials we ever introduced. Its large golden-yellow, long-spurred flowers are produced in great abundance from densely-tufted plants, which maintain a long succession of bloom. This species has not yet flowered with us; but magnificent dried specimens of the blossoms have been forwarded to us from North America. These are not unlike very large examples of *A. cœrulea*, with long straight horns. So far as we can ascertain, this plant has nothing whatever to do with *A. aurea* of Roelz, of which the flower is scarcely half the size, of a sulphur yellow shaded with green."

## THE INDOOR GARDEN.

### RHAPIS FLABELLIFORMIS.

THIS, as our illustration suggests, is one of those plants that are indispensable in warm conservatories planted in the natural style; for ornamenting the margins of water, or for the embellishment of a small island, nothing could be more striking or appropriate. It is fond of water, and will stand more rough usage in the way of transplanting than any other Palm with which I am acquainted. For vases in rooms too it is admirably adapted, and it is exceedingly useful in the subtropical garden. Being a native of China and Japan, it will stand a moderate amount of cold. As a general decorative plant it has this advantage, that it never grows larger than from 8 to 10 feet in height, and it can be increased by divisions of the roots. In this operation make a clean cut and place the young plants in bottom heat until they have got established.

*Rhapsis flabelliformis.*

From this plant are made the smart little rattan canes which one often sees in shop windows, part of the root being formed into a knob or head; they are very hard and strong, and when polished nearly black.

J. CROUCHER.

### CULTURE OF THE CHINESE PRIMULA.

(*P. SINENSIS FIMBRIATA.*)

THIS belongs to one of the most popular and interesting groups of winter and early spring flowering plants that we possess; and from the ease and freedom with which it can be cultivated and increased, combined with the great variety, richness, and purity displayed by its flowers, which are produced in the greatest profusion, it is alike suitable for the embellishment of the conservatory, greenhouse, drawing or sitting-room; and, moreover, it may, with ordinary care, be grown by all possessing a few square feet of glass. This *Primula* may be readily increased by means of cuttings made

of the side shoots, or by divisions; but, except in the case of double varieties and scarce and novel types, these modes of increase are but seldom resorted to, as, by taking ordinary care to prevent promiscuous fertilisation (which generally results from the action of bees), it reproduces itself true from seed, which should be sown annually; it therefore becomes important to secure seed from the very purest "strains," or disappointment may possibly be the result. I find the *P. sinensis fimbriata rubra* strain to be by far the best when subjected to gaslight, such kinds as *Kermesina* or *Splendens*, which is bright, fiery crimson by day, being poor and washy, in comparison with the former, under artificial light. Several of the whites are of peerless purity, and most effective for all decorative purposes; it would therefore be invidious to specify particular types.

#### SEED SOWING.

The time for sowing should be regulated according to the period at which it is desirable to have the plants in bloom. For autumn and winter flowering, where the object is to have as large plants as possible, the seed should be sown about the middle of February, certainly not later than the first week in March. Equal parts of sandy loam, peat, leaf-mould and sand passed through a quarter-inch sieve will be found a suitable compost, and the seed pots or pans should be amply drained; at this dull period about one half of the depth should be filled with crocks, which may be covered with a layer of the siftings, filling in the compost to within half an inch of the top, pressing it moderately firm and leaving the surface perfectly smooth. Presuming that the soil has been used in a healthy state as regards moisture, a slight watering from a fine rose will be sufficient; then allow the pots to stand until the soil has become somewhat dry before the seed is sown, and cover it slightly with compost put through a fine sieve; merely cover, in short, sufficiently to hide the seed, settling it down by means of a gentle watering; afterwards plunge the pots in a propagating bed in a temperature of about 75°, and shaded from the sun, when the seeds will quickly germinate.

#### TREATMENT OF THE YOUNG PLANTS.

These must have prompt attention immediately they push through the soil, removing them to a position near the glass, free from stagnant air, to prevent damping off, and to promote a sturdy habit, being careful in watering to wet the tender leaves as little as possible; as soon as the plants get sufficiently strong to handle nicely, if convenient space is at command, they should be potted off singly into the smallest sized pots, and failing these prick them out into seed pans, using the same compost as recommended for the seed; place them in a pit or frame with a genial temperature, and they will make rapid progress, admitting air in proportion to the strength of the plants, which must be screened from bright sunshine. When the pots have become filled with roots progressive shifts may be given; for ordinary purposes six or seven-inch pots will be sufficiently large, using more loam in a rougher state as the plants get stronger. If the soil is not in sufficiently good heart, it will be necessary to enrich it with thoroughly rotten manure which has been dried and freed from worms. A free system of drainage must at all times be secured, as *Primulas* of this class are impatient of stagnant water.

#### SUMMER TREATMENT.

*Primulas* naturally delight in moderately shady positions, *i.e.*, they should be screened from the mid-day sun; and to ensure that important object no better site can be chosen for them during the summer months than the north side of a hedge or wall; they should be set in an ordinary frame, to which air should be admitted on every favourable occasion. When the plants have become thoroughly established in their blooming pots, the lights may be entirely removed at night during mild weather, but in doing this care must be taken not to subject them to heavy rains, as the foliage quickly suffers from any excess of water hanging upon it. In watering, too, care should be taken to wet the leaves as little as possible, promoting humidity in the atmosphere by freely sprinkling the material on which the plants are standing in preference to syringing overhead. Water carefully at the root, guarding against any excess which the plants cannot take up. Weak liquid manure-water will be beneficial when

the flowering pots are full of roots, and more particularly during the time when they are throwing up flower-heads. Remove the bloom-buds as they appear until such time as the plants are wanted to bloom, an operation which will greatly strengthen them. They are easily injured by being subjected to cutting draughts, which should at all times be studiously avoided. A moveable shading should be provided, to screen them from bright sunshine, and for this purpose nothing answers better than a piece of serim-cloth attached to a round piece of wood or roller a few inches longer than the lights. This can be rolled on and off by one man with greater facility and more neatly than a loose covering, more particularly where several lights have to be covered in one length. White-washing the glass and such permanent means of subduing the glare of the sun are objectionable, as they are sure to engender an enfeebled constitution in the plants.

#### SUCCESSIONAL SOWINGS.

A successional sowing should be made in June for spring flowering, and as the weather is then hot and dry, it is advisable to water as little as possible before the seeds germinate. The soil should be kept an inch and a half below the rim of the pot, over which a piece of glass should be placed and a covering of moss, which should be kept constantly wet. This will facilitate germination; artificial heat at this time of the year is unnecessary.

#### LARGE SPECIMENS.

Where it is desirable to have as large plants as possible for conservatory embellishment, the late flowering batch form the best subjects for effecting that object; slightly rest them for a short time after blooming, previously to potting them; afterwards shake them out and repot, keeping them close and shaded from sunshine till the roots have been brought into action, gradually inuring them to air, and potting them on as required. Such plants make splendid specimens, which flower early and freely.

#### DOUBLE VARIETIES.

These are most profuse bloomers, and where cut flowers are largely in request during winter, they are invaluable, as the blooms stand longer and better than those of the single sorts. They are, moreover, grand subjects for bouquets, when attached to wires in the form of single blossoms. Upon the whole they are less robust in constitution than single kinds, but they may be treated, as regards general management, much as detailed above; they strike freely from cuttings taken after blooming, placed in bottom heat, and kept close until they have struck root.

#### HOW TO PREVENT DAMPING OFF.

It may be mentioned that to be perfectly successful in blooming Chinese Primroses during the dull months of the year, it is important that they should be afforded a light, airy position near the glass. A lattice-work stage is the best possible support on which to set the plants, admitting, as it does, the air to pass freely amongst them, whilst at the same time there is no chance of water hanging about them; the best temperature for them is one averaging about 45°. In low localities extreme difficulty is often experienced in preventing them from moulding-off in the absence of an arid atmosphere.

G. WESTLAND.

Witley Court, Worcestershire.

#### CAMELLIAS PLANTED OUT.

Those who have seen such magnificent Camellias as those in the nursery of Messrs. Pince & Co., of Exeter, in the gardens at Bicton, at the late Mr. Byham Martin's, at Kingston, and other places, must admit that, however useful and beautiful Camellias may be in pots or tubs, their true grandeur and magnificence can only be brought out in the open border of a conservatory. It is indeed surprising how seldom we meet with Camellia-houses pure and simple, even in the best places; and yet the value of the Camellia was appreciated before that of almost any other plant. Most of the old gardeners had a Camellia-house and an Orangery, or one house which served for both. These were mostly gloomy architectural structures, in which the plants pined and died. Then came a description of glass houses, which, unshaded, admitted too much light, and

until our ventilation and means of charging the atmosphere fully with vapour are much more perfect than they are, it will assuredly be found that shade, or what amounts to nearly the same thing, a considerable distance from the glass, is essential to the perfect health of Camellias. They need no shade when expanding their blooms in the dead season; but if late flowers are wanted, they will last longer, and be also more beautiful while they last, if they are shaded from the sun from twelve to three after the 1st of March; when in full growth, too, partial shade in an atmosphere approaching saturation assists them greatly. It follows, therefore, that the heaviest roofed houses in the garden will grow Camellias very well. I have even seen fine specimens beneath a plastered roof; but I would not recommend such a one. A roomy, lofty span-roofed house, with a moveable roof, would be best. The entire sides should likewise be capable of being moved for ventilation, as air in motion in sufficient volume is one of the surest antidotes against leaf scorching or burning.

As to soils, the different kinds that have been recommended have been well nigh endless. One of the surest signs of horticultural progress in these times is the general condemnation of complicated nostrums or composts. Now, three soils complete our curriculum—peat, loam, and leaf-mould; and a great many dispense even with the latter. These, with the addition of sand, are all we want. Some of the best Continental as well as English growers grow their Camellias either in peat or in loam. Some declare the one best; some the other; and equally good plants have been grown, and still are grown, in both; and even fine Camellias have been grown in a mixture of both; but such a mixture I do not recommend. The best Camellia soil is turfy loam full of fibre, cut only about 2 or 3 inches thick, broken up and mixed with about a sixth part of sharp silver sand. Camellias root in this rapidly, and form wood and leaves and flowers of surpassing health and beauty. Peat of the same turfy character answers equally well, and, therefore, I see no good in mixing the two together. As for cow-dung—fresh or rotten—and all other stimulants, don't use them. Camellias like rich food when they are growing freely; give it to them daily in their drink—house sewage, manure-water—natural and artificial—from the drainage of the farm-yard and soap-suds to pigeon's dung and guano-water. Weak and often should be the rule, though Camellias will bear stronger doses of manure-water than most plants.

A border from 2½ to 3 feet deep of turfy peat or loam, with a few inch bones and bits of charcoal, and resting on 6 inches of open drainage, suits Camellias well. Even for top drainage I should give only more loam and turf. The drainage may seem excessive, but it is not. Camellias can hardly have too much water given them when growing freely; yet stagnant water ruins the plants, and causes bud-dropping instead of promoting their opening into flower.

In planting, the roots should be disentangled as much as may be required without breaking them, and the soil should be made as firm around them as can be done with the hand. The more the balls are matted, the firmer must the earth be made, else the roots may fail to get hold of the fresh earth. Water thoroughly after planting, to consolidate the earth, and settle the roots into their new home. During the growing season it is impossible to keep the air too moist. Send a deluge over the plants two or three times a day by means of an engine hose. This will encourage growth, promote strength, and ensure cleanliness. After the growth is matured, the plants cannot be kept too cool throughout the summer. If unroofed, care must be taken to guard against any sudden rise of temperature when the glass is put on in the autumn. Any sudden change is apt to loosen the flower-buds, and once this is done, no power or skill can tighten them again.

As to varieties, it is almost invidious to pick and choose among Camellias. Jubilee is, however, my favourite for beauty, and Pergia for forming a tree or covering a wall with the utmost despatch. It also bears a noble flower. The Double White, Fimbriata, Lady Hume's Blush, Marchioness of Exeter, Beah, Countess of Ellesmere, Cup of Beauty, De la Reine, Double Red, Elegans, Chandleri, Formosa, Tricolor, and Fulgens are a few, at once beautiful and cheap. There are an immense number of newer kinds, some of them larger and more beautiful than these, but the above will disappoint no one, and

those who intend to purchase novelties or to invest largely in Camellias should first of all visit some of the largest nurseries now when the plants are in flower. In cases in which this cannot be done, I will add a few more names, mostly of old varieties, but of such as are good and cheap, viz.: *Augustina superba*, *Aurora*, *Comtessa Lavinia Maggi*, *Bonomiana*, *Jenny Lind*, *Imbricata*, *Mutabilis*, *Monarch*, *Mathotiana*, *Rubens*, *Valteraredo*, *Triumphans*, *Saccoi nova*, *Candidissima*, *Jeffersoni*, *Leopold I.*, *De la Reine* (red), *Elegans* (Chandleri), *Napoleon III.*, *Prince Albert*, *Perfecta*, *Queen of England*, *Wilderi*, *Princess Marie*, *Countess of Orkney*, and *Reticulata*. (single and double). D. T. FISHER.

#### WELWITSCHIA MIRABILIS.

THIS is one of the curiosities of that curiosity-producing country, Western Africa—though as yet we have but little knowledge of what treasures may be locked up in that vast unexplored territory. It was first discovered by the late Dr. Welwitsch on the plateau of the Benguela coast, in 15° 40' south latitude. It has also been found by Mr. Bains in Damara Land. It is related to the Coniferous tribe, and bears clusters of cones like those of the common Larch. The leaves resemble long, broad strips of leather, and are composed

to produce 100 or more flowers. The individual blossoms are 3 inches across; the labellums are pure sulphur yellow, while the sepals and petals appear to be of a deep yellow, heavily blotched and barred with rich purplish or brownish crimson. The collector speaks rapturously of the beauty of a spike of 47 flowers expanded at his side while writing. Judging by one of the specimens received, the species forms doubly compound spikes when very luxuriant. The blossoms have a close affinity in general appearance with those of *Oncidium splendidum* and exhale a delightful perfume like that of Violets.—*Beta*.

**Daphne indica rubra.**—This fine old greenhouse and conservatory plant blooms during the winter and spring months, when its exquisite fragrance is quite delightful. Daphnes are better on their own roots than otherwise, as grafted plants are short-lived. When planted out I have had this fine *Daphne* cover a long side wall in an orangery, where, during spring and early summer, the amount of trusses cut from it was perfectly marvellous, and the gentle moist heat to which the orange trees were treated in spring suited the *Daphne* admirably. Those who intend planting out Daphnes in their conservatories must bear two things in mind; the first is thorough drainage, and very little space must be allowed for the roots to run in; the soil to be used should consist of good, rich, turfy loam and peat, in the proportion of about two parts of the former to one of the latter, adding to this a small portion of sand and a little broken lime rubbish; the soil should be made firm. These remarks

*Welwitschia mirabilis.*

entirely of strong fibre, not unlike uncombed Hemp. The roots, which descend deep into the sandy soil, form when dry quite a mass of stringy fibre. The body or trunk resembles a gigantic fungus or roughly made bench, with a suture crossing the centre somewhat like a miniature valley, the two sides of which rise slightly to the margins, where the growth is made. If the plant could be got in quantity, its fibre would doubtless be useful for cordage. It is to be regretted that at present this singular plant is not in cultivation, a circumstance doubtless owing to its not being a plant likely to meet with a ready sale; and to our botanic gardens having given up the introduction of new plants. If introduced it would doubtless grow freely in a dry and moderately warm house. One cannot but be surprised that this odd-looking plant should ever have been thought worthy of the specific name "*Mirabilis*." Vegetable monster, many may think, would have suited it better.

J. CROUCHER.

**Oncidium tigrinum** (Llav).—This magnificent Orchid, which is the long sought "*Flor de Muertos*" of the Mexicans, has at last been discovered by the collector of Messrs. J. Backhouse & Son, of York, by whom magnificent plants of it have been recently received. In the wild state it usually bears from 10 or 15 to 50 flowers on branching spikes, 2 to 4 feet long, while luxuriant specimens appear sometimes

will apply equally well to Daphnes grown in pots, for at no time, or in any position, should they be allowed much pot room; neither should the drainage be snuffed to get out of order. If the pots are full of roots, a little weak artificial manure applied occasionally will be found very advantageous.—*Farmer*.

#### NOTES AND QUESTIONS ON THE INDOOR GARDEN.

**Vanilla.**—During the year 1871, 17½ tons of Vanilla were exported from Reunion, and we are told that "the extravagant prices lately obtained for this article have much stimulated the cultivation," so that it is probable much larger quantities will be grown and exported than hitherto.

**Arpophyllum giganteum.**—This is a beautiful plant, the leaves of which are 2 feet long, and are borne on slender pseudo-bulbs. The flowers are deep rosy purple, small, but densely and symmetrically arranged on cylindrical spikes from 12 to 14 inches long. When well grown the plants flower freely, and form objects of singular beauty. They grow freely in fibrous peat, one-third turfy loam, freely interspersed with lumps of fresh charcoal, and an abundance of crocks. They like plenty of water when growing.

**Campanula garganica.**—This pretty dwarf species, with its bluish-purple flowers and tinted white centres, is rapidly becoming a charming object cultivated in pots in a cool conservatory. I find that if planted in good soil in 32 or 24-sized pots, the plants will do well for two or three years without the necessity for being repotted. Mingled with pots of the early white Roman Hyacinth and other spring-blooming plants, this attractive dwarf hardy Campanula supplies a line of colour I should not otherwise possess, and, as it is a continuous bloomer, the dense mass of flowers which it affords lasts for a considerable time.—R. D.

## ROMAN HORTICULTURE.

THE particular processes followed by the ancients, or, not to go further into antiquity, by the Romans, when at work in the orchard, the vineyard, or the kitchen garden, of course were very simple. The former are detailed at length by Columella, and are noticed, more or less copiously, by Pliny and Virgil; but concerning garden operations they have very little to say. The most interesting circumstance connected with the cultivation of the Vine was that of its being usually led into a tree, an Elm having the preference, so that allusions to the "marriage" of the two become frequent in the classical poets; while the Plane, which was never so employed, received the name of *Cœlebs*, or "the bachelor." Digging, raking, seed sowing, clipping, must needs be much the same everywhere; it is only when we come to the fine arts department of horticulture—budding, grafting, inarching, pruning, training (as practised with wall-fruit trees), forcing, and so on, that there can be much to distinguish the practice of nations; and these were precisely the horticultural exercises in which the Romans did not shine, partly because of their want of physiological knowledge, partly because their fine climate anticipated so many of the exigencies felt in the north. The lovely climates of the edges of most of the countries washed by the Mediterranean rendered horticulture, 1,800 years ago, the same as now, in those parts, in many respects a sinecure; and the same, no doubt, is one of the chief explanations of the fact that horticulture as an art invariably makes more progress where the skies and the atmosphere are congenial than where benignant. Under the influence of kindly ones nature does so much of her own accord that the gardener can afford to dispense with artificial aids, even if he thinks of them. When speaking of Rome, and more particularly of Italy, as a seat of delightful climate for the horticulturist, and one that is less of a stimulus to his ingenuity than England—the Western side alone is to be understood. The provinces next the Adriatic are very different, since they lie exposed to the cold winds from the north-east, without a ridge of Apennines to protect them. The Italy of history and the Italy of invalids consists almost wholly of the western side, where, too, we must look for its celebrated cities—Rome, Naples, Florence, Pisa, Genoa, and Salerno. We may understand the matter quite well from the condition of things in different parts of England. Compare, for instance, Lancashire and the Isle of Wight; or the gardens in the suburbs of Manchester, where the Arbutus and the Bay tree get cruelly put to death before they can attain the height of a man, with the southern coasts of Devonshire and Cornwall, where the Myrtle and the Eucalyptus stand the winter unscathed. After all, it is better for the spirit of a true gardener that he should live where nature has to be conciliated than in a region where he has only to accept and enjoy indolently. Bananas that in India come of themselves may be good, but Grapes and Peaches that have to be enticed are the real benefactors.

Another thing tended to the depression of horticulture as an art with the ancient Romans. The national taste lay in the excitement of great victories and grand spectacles, like those of the Circuses. The fancy was not for the sweet and peaceful pleasures of the garden, since these consist, in reality, of thoughtful and scientific work. A gardener rightly used is to a horticulturist what his "study" is to a literary man,—a place which implies the calling forth of the best features of things, watching, waiting, and experimenting. Pleasures like these, so alien to warfare and uproar, the Romans did not care for, though, as we have seen, they liked well enough the idea of rural retirement, and to be quiet at a country seat where there was nothing to do. But the calm of an artificial and unsuggestive garden is a very different thing from the inspiring tranquillity of one to which a man resorts because full of plants that he loves and lives with. The capacity for this description of plant-love was precisely that in which the Roman failed. He was not to blame; the spirit of his age denied it him, but he was none the less the loser. The Roman did not understand, as every gardener worth the ennobling title does now-a-days, that a garden is a laboratory, like a chemist's; the test tubes, the re-agents, the laws of affinity, all beautifully existent in it in principle, sources of the most admirable knowledge, donors of the most exquisite

delights, and all at the same time higher in quality exactly in the degree that distinguishes between inanimate things and living ones. Mere care for a garden as a place for idleness and the display of colours, and where thought and enterprise are to be laid aside, may be excusable, and even amiable, but can never become enviable, and is always liable to degenerate into the spirit that takes vacant fops and mincing flirts to the flower-show, where they stoop to smell the "green rose," and declare its perfume "heavenly."

The Romans again were too deeply enamoured of grandeur and magnificence; they preferred splendid buildings to the fairy-land of a delicate garden; they were, moreover, an impatient people, demanding rapid realisation of their desires; and as an arch of triumph, a colonnade, or a temple could be seen to grow to its full height, as it were, more rapidly than a garden, which attains perfection only by slow degrees, horticulture was left to the simple purveyor of commodities. There is nothing like a garden, as every true gardener knows, for teaching patience. In the garden our hopes and wishes have to lie like a chrysalis, biding their time; the wings and plumage are forming, nevertheless, all the while, and by-and-by see how beautifully Psyche comes forth! What we have said of course applies most especially to Roman horticulture in reference to flowers and ornamental plants. But it bears directly also upon horticulture in the general sense, and very suggestive is it to ponder for a moment on the incuriousness of an old Roman gardener as contrasted with the untiring and multiform zeal of an English one, say even in the single matter of obtaining superior sorts by hybridization or cross-breeding. The fine climate of Italy and the beauty of its spontaneous productions no doubt account at the same time for the ruling indifference as to exotic plants, excepting trees of great usefulness. These would seem to have sufficed for satisfaction of heart, and no doubt there was many an echo heard to the patriotic verse in the second *Georgic*; "yet neither the forests of Media, that richest of countries, nor lovely Ganges, nor Hermus that 'rolls down its golden sands,' *laudibus Italia certent*, can vie with Italy in desert of praise."

But if they needed no hot-beds or "frames," and were liberally provided for by nature, still, from certain allusions in Martial, it would seem that the Roman gardeners had notions as to the art of "forcing." There appears to be no doubt that the Emperor Tiberius, who was very fond of Cucumbers, had a supply throughout the year, obtained by means of moveable stoves, which contained boxes for the plants, and allowed of being wheeled out-of-doors during fair weather and while the sun was shining. These stoves were called "specularia," from being fitted with slabs of talc, "*lapis specularis*," the material employed for windows before the invention of glass, and possibly served well enough for the purpose mentioned; but they would never allow of the forcing of Peaches and Grapes, which certain writers have imagined to have been practised. Anything special that may have been accomplished in regard to Grapes would seem to have consisted not in obtaining an *early* crop, such as would now be understood by forcing, but in securing a *late* one. This would be effected by the destruction of the early or first flood of bloom, and the encouragement thus given to the development of a second; and if the plants were kept in a building that could be warmed when necessary, we can quite understand not only how Grapes could be obtained in winter, and the "Roses" which the poet alludes to, but his playful hit at his friend's domestic arrangements, when he says he would rather be the guest of the fruit trees than of the owner, so much more comfortable was their lodging! LEO GRINDON.

---

**Mammoth Sea-Weed.**—While Professor Agassiz was on his scientific expedition to South America this season, he found among other curiosities near Patagonia a gigantic sea-weed, the largest known, in fact the longest growth made in the vegetable world. This Alga grows along the coast in from six to twenty fathoms of water in vast beds, and so compact that mariners avoid them for fear of an inextricable entanglement. The stems are of immense growth, some of them reaching the enormous length of 1,000 feet. The "Hassler" passed patches of the Alga in open water, and the party saw large sea lions lying upon the weeds.

## GARDEN DESTROYERS.

## THE GOAT MOTH.

(COSSUS LIGNIPERDA).

ONE day last autumn we observed two or three people gathered round a tree in Ladbroke Grove, Notting-hill, and had the curiosity to enquire what was the matter, when we were gravely informed that the tree was inhabited by venomous caterpillars. We knew the tree well. It is a Poplar, which has for years past been tenanted by a colony of caterpillars of the goat moth. It is literally riddled by their galleries; in some places a wet, offensive exudation of rotten sawdust and putrescent-looking stuff issues from holes in the bark; and here and there large pieces of bark have given way, revealing the gaping ravages within.

The caterpillar of this moth is flatter than usual, the texture is the shining skin characteristic of maggots; but its chief distinction is that its upper surface is uniform red, passing into flesh colour or whitish or yellowish on the under side. The red is paler in the younger examples; at first rose-red, then lip-red, then a slight dinginess comes in, and we have it Indian red; from that it goes to Venetian red, and finally, when the insect is full grown, it attains a deep tawny port or claret hue. Lastly, when about to pass into the chrysalis state, the blush fades away from its countenance, and it turns into a kind of unhealthy-looking yellow. The head and a bilobed mark (lobes pointing backwards) on the segment behind it are black. It takes three years to attain maturity, and lies in the pupa state for another year, so that the natural term of the life of the insect is four years. It feeds on the solid and sound wood of various kinds of trees, preferring the different kinds of Willow and Poplar, and next to them the Elm, but it by no means restricts itself to them. It is also found in the Lime, the Alder, Beech, Walnut, and different fruit trees, and it has even been met with in the hardest of all our woods, the Oak. It is curious that in different countries it seems to give a preference not always to the same trees. In the neighbourhood of Paris, it is especially the Elm that suffers. It has done immense damage there to that tree. Here, the Elm is comparatively seldom attacked; it is the Willow and Poplar that are first favourites. It would appear to be the same in Germany, where it is called the Weidenbohler or Willow-borer. The mischief which this caterpillar does is not merely the eating away of the solid part of the timber; that in itself may be carried to a great extent without destroying the life of the tree. Its life resides only in the outer circle of cambium, or at most in it and the sap-conveying tubes forming the outer circles of timber; the inner wood is dead matter, and might all be removed without other bad consequences than the deprivation of support. Of course, without the support, and the continuous support, of the inner wood a tree could not long stand. It would be broken over by the wind, and when only part has been removed, it is at that weak part that the fracture takes place. But the goat moth caterpillar not only removes much of the substance of the inner timber, but begins by removing the cambium or living part, and moreover, damages what it leaves, and lays a foundation for general rottenness and decay.

It is common all round London, and trees affected by it may easily be detected by the disagreeable scent infused into them by this destructive caterpillar. We have not noticed it

in Kensington Gardens or Hyde Park, but it is in Battersea Park, in Kensal Green, in Holland Park, and in some of the neighbouring gardens, as well as in various squares and boulevard streets.

It is the insect which Lyonnet made the subject of his celebrated anatomical researches in that class of animals, and he could not have found one better adapted for his purpose. It is the largest European caterpillar, and nothing but a giant among caterpillars could have enabled him to dissect, reckon, figure, and describe as he did 4,061 muscles in its frame.

As soon as it is hatched the caterpillar begins to feed on the inner and tender part of the bark and cambium; it then passes on to the liber, beyond which in its first year it does not go. In the second year it goes deeper, but still confines itself to the soft outer layer of wood. The third year it has become so strong and powerful that it now pushes its way even into the heart of the tree. It arrives at its full size in summer, when it usually makes itself a cocoon of the sawdust or debris glued together by silken matter; this cocoon is usually built in one of its galleries close to a sufficient opening. Sometime s, however, the caterpillar comes out of the tree and makes its cocoon in crevices in the stem near the root of the tree, or in the earth at its base, perhaps at times even at some distance from the tree. The inside of the cocoon is smooth and comfortable, the outside rough. The pupa is brown, and, like its ally the leopard moth, has a series of teeth or spines on the margin of the back of the abdominal segments, which enable it to shift its position when the time to make its way out of the cocoon arrives. The empty open pupa is usually left sticking half out of the cocoon.

The moth comes out between the latter part of June and the end of July. It is of a brown and smoke colour, marbled with white. The antennæ are pectinate, both in the male and female. We have already, under the head of "Zauzera," mentioned the peculiarity that its mouth is unprovided with tongue or

means of feeding. The female is very fruitful, as many as 1,000 eggs having been counted in one individual; and it is reckoned that the usual number of eggs laid is, on an average, 700 for each female. They are deposited in the bark, near the base of the tree, by means of a strong, hard, tubular ovipositor. The eggs are smoke-coloured or dirty white, rather large; but not so much so, perhaps, as might be expected from the size of the insect.

The habit of the moth is to rest on the trunk of the tree from which it has emerged, or on a neighbouring tree, with its wings folded like the roof of a house. It never goes up among the branches, but rests on the stem near the bottom, so that it is not difficult to catch it when the eye is once habituated to distinguish it from the bark on which it rests—not so easy a task as, from its large size, might be thought; for the colour and marbling of the insect are so wonderfully adapted to those of the bark of the tree, that an uneducated eye is almost sure to pass it over. It deposits its eggs equally low down on the tree—so low that a mode recommended for protecting trees from them is to plaster the base of the tree, at the proper time (June to September), with a thick coating of a mixture of clay and cow-dung, which the ovipositor of the female cannot penetrate. The remedy recommended by Boisduval is to buy up all the females that can be found; a shilling apiece would set the children of the neighbourhood to work, and he thinks it

Goat Moth and Caterpillar (natural size).

worth the money. It seems to us that a proper precaution would be to cut down every tree that is found to be seriously attacked. There is no getting at the caterpillars in the galleries, although poking them with pointed wires and blowing tobacco smoke in upon them have been proposed as a means of doing so.

Their work is easily recognised from the size and proximity of the galleries they make. The injury they do is often very great; and, unfortunately, after a tree has once been attacked by the Coccus, it never recovers, although it may languish, spreading infection all around for a long series of years. When at last cut down, the timber is so bored and damaged as to be fit for nothing but firewood. This species extends over the whole of Europe. There are five allied species in North America, and also species in India. A. M.

#### INSECTS THAT INFEST ORCHIDS.

Most plants are subject to insect pests, although it is not often that they do any serious damage, that is, if ordinary precautions are taken by the cultivator or his assistants to prevent injury. Thrips is one of the worst, especially if the temperature of the house is excessive and the atmosphere dry; but in the houses devoted to cool Orchids this ought never to be the case. The cool, moist atmosphere of the Odontoglossum house is not the most favourable for insect life. Red spider sometimes, though rarely, makes its appearance in a dry corner, and if there is a yellow thrips in the house it is almost certain to commence operations on the juicy foliage of *Cypripedium Schlimmi*. The yellow fly, so common in Orchid houses, will infest the flower-spikes of *Odontoglossum* and *Calanthes*, but two or three moderately strong doses of tobacco smoke will clear them out. Tobacco rag, *i.e.* the old coverings of the rollers used in the manufacture of "twist," is far preferable to the vile rubbish sold as tobacco paper, and the chances of burning are considerably reduced by its use. In smoking *Odontoglossums* great care must be taken, or the smoke will do serious damage. They should never be subjected to smoking if in the least degree shrivelled by a hot and dry atmosphere. Mr. Culley, who has charge of the well known collection of "Cool" Orchids at Ferniehurst, never hesitates to smoke his *Odontoglossums*, but it must be remembered that their bulbs and foliage are fresh and plump, in which condition it rarely harms them, though Mr. Bateman, whose name in connection with Orchids is well-known, strongly objected to the use of tobacco smoke in the *Odontoglossum* houses.

Orchids grown in cool houses rarely suffer from the small white and brown scales which make such sad havoc among *Acridas* and *Vandas*; still, if they should put in an appearance, it will most likely be in the warm end among the *Cattleyas* and *Trichopilias*. If the plants are regularly sponged over with tepid water, and kept free from dust and dirt, they are not near so liable to the attacks of insect pests as they otherwise would be, and the plants look all the better for the trouble.

Some insecticides are very effective in the destruction of thrips and green fly; we have used "Fowler's" with success and also "Frettingham's." Messrs. Parr & Atherton, of Nottingham, have registered an effective contrivance for applying the latter kind in the form of fine spray, and by the use of this invention a little of the compound is made to go a long way, and it forces it in among flower-buds of the most delicate description without injuring them in the slightest degree. This latter is very useful when but a few individual plants are affected, but when a large quantity of good-sized specimens has to be cleaned there is no better contrivance than the water-barrow we have figured. This can be half filled with any useful insecticide and then the plants may be entirely immersed so as to ensure the death of every insect with which it may be infested, or the plants may be held partly in the liquid and syringed thoroughly without any of the compound being wasted. Anyone who once possessed this useful contrivance would never care to be without it. I would caution the unwary cultivator against the use of methylated spirits for clearing Orchids of white and brown scale. It kills scale without a doubt, but seriously disfigures the foliage operated on, more especially if it gets caught by the sun's rays soon

after it is applied. The following are well-known methods of capturing and destroying insects that infest Orchids generally.

For Cockroaches and crickets, place bell glasses, bottles, smooth or glazed pans, so that the sides are in a slanting position, and fill them with treacle and water, in which the insects drown themselves. Woodlice may be destroyed by placing Potatoes cut in halves about the plants, which should be examined every day till they disappear. Green-fly may be killed by smoking, but it must be done very carefully with good tobacco paper, or the leaves of some will suffer. If to 1 lb. of tobacco paper, 1 oz. of saltpetre be dissolved in water by boiling it in a small pan, and sprinkled over the paper, or the paper soaked in it, it doubles the strength of the paper without much increasing the risk of burning, still only half the quantity must be used, and if a certain weight be not strong enough for a house, it may be gradually increased. Three smokings on successive nights will kill thrips; or for either thrips or spiders, if the plants be washed with a mixture of 1 oz. of bitter aloe and 1 oz. of tobacco to a gallon of water, it is safer than mixtures containing soft soap or turpentine, which are apt to burn the plants or spoil the leaves if it gets in the crowns. Tobacco water made from pure tobacco in bond, free of duty, may be had at many places, and at the nurseries at 3s. 6d. per gallon. They should be washed immediately on its appearance, and the plants examined a time or two about once a week after, and if done as soon as seen, and not allowed to spread, there is little difficulty in keeping them clean. Ants may be destroyed by a few fresh, unpicked bones being placed for them, or sponges wetted and filled with sugar, or treacle in bottles or pans. Slugs may be collected by a little bran placed under some Cabbage leaves, or pieces of bark with the hollow side down, which is also a good trap for woodlice. F. W. B.

**Mining Rose Insect.**—It has, no doubt, been observed by many that in autumn the leaves of the Rose tree on their upper surfaces are very often marked in various directions with broad brown lines, having a narrow black one running down the middle. This curious appearance is caused by the small caterpillar of a minute moth (*Microsetia (Tinea) ruficapitella*) which feeds inside of the leaf. When full grown, the caterpillar is nearly two lines long, of a yellow orange colour, with a brown mark down the back, the head very flat and sharp, and light chocolate. The brown mark on the leaf is caused by the epidermis drying, from the insect having eaten the parenchyma, or substance of the leaf beneath; the black one by its egesta, which, during its young state, continually stop up the mine. When full grown, which is about the 24th of October, it eats out of the leaf, and crawls down the branches and stem, until it has found a convenient place to fix its cocoon. This is the only time when it finds it necessary to make use of its legs, which seldom exceeds an hour, sometimes less. The cocoon is very flat, and at first of a pure white, which is changed by the first shower of rain to light orange; it afterwards becomes of a deep brown, so nearly resembling the bark of the Rose tree as only to be distinguished by a practised eye. This change takes place very rapidly. When kept dry, the cocoon remains perfectly white, and produces the moth at the usual time, as well as those which have been saturated with water. The pupa is light brown, of an oval shape, about a line long, and half that in breadth, and the perfect moth appears about the 12th of May. The moth is the red-headed pigmy (*Tinea ruficapitella*, of Haworth). The upper wings are gold coloured, with the apex purple, the head ferruginous, the expansion of the wings 2½ lines.—(Q.)

**Scale Insects.**—Kindly tell me the name of the scale of which I send specimens.—P. C. (The scale sent is the Mussel scale (*Aspidiotus conchiformis*), and unusually numerous. We have seldom seen so bad a case. Where they are not numerous, brushing them off with a hard nail-brush is recommended, but here such a remedy would be useless. It is a case for strong measures, and we would recommend you to paint the whole affected branches with quick-lime. You must, however, take care to proceed with caution, or you may injure the trees.—A. M.)

**Bruised Laurel-leaves a Cure for Aphis.**—If the infested plant is small, take three or four Laurel leaves, beat them all over with a hammer, so as to thoroughly bruise them; then place them round or under the plant and cover; a small bell-glass does best. Let all remain closed for a few hours, and the aphides will be found dead, each hanging by its proboscis only. If this process is repeated within a day or two, to make sure, the plant will be perfectly freed, and in some cases it is not again attacked. This way of killing aphides may be acceptable to those who dislike tobacco smoke; all danger arising from an overdose of it to a very tender plant is avoided; and the Laurel is so generally grown, it must be almost everywhere at hand for the purpose.

## THE ARBORETUM.

## HARDY TREES AND SHRUBS.

BY GEORGE GORDON, A.L.S.

THE ENTIRE-LEAVED NEPAUL MAPLE (ACER OBLONGUM).

THIS, in its native country, forms a handsome evergreen tree 20 feet high, with a loose spreading head, and long, slender, smooth glaucous shoots; but in England it is tender and requires protection in winter, particularly for the first three or four winters after planting: and although it may after that time get killed down to the ground in severe winters, it will

Full-sized leaf of *Acer oblongum*.

always shoot up vigorously the following spring, particularly if protected at the base by a layer of old leaves, and frequently produces during the following summer shoots from 4 to 5 feet long, which, when clothed with their fine Laurel-like leaves, form a very attractive bush. This Maple is a native of the lower or outer mountains of Nepal and Bhootan, where it forms woods at elevations of from 2,500 to 4,000 feet. It was first introduced in 1824. The leaves are oblong-lanceolate, taper pointed, quite entire on the edges, rounded at the base, thin and leathery in texture, persistent, and set on rather

long slender footstalks. They are deep glossy green above, very glaucous and white beneath, and are quite smooth on both surfaces. The flowers are small, pale yellow, and are produced in loose, short, terminal compound racemes, in February and March. The fruit or keys are rather small, with hairy carpels, particularly when young, and short smooth wings, a little spreading. The synonyms are *Acer laurifolium*, *nepalense*, and *sempervirens*. The length of a full-sized leaf is  $6\frac{1}{2}$  inches, including the foot-stalk, which is  $1\frac{1}{2}$  inch long, and the breadth is  $2\frac{1}{4}$  inches.

## MOVEMENT OF THE SAP.

I FULLY concur with your correspondent, "A. M.," (see p. 160) that the discussion of this topic must be attended with useful results; and I therefore offer a few further remarks in reply to him, and in explanation of the points upon which he and I seem to differ in opinion. He attaches more meaning to the word "suction" than I had supposed when writing my last communication; but I confess that in my judgment, the word "assimilation," which, as a vital process, includes the idea of suction and a great deal more, is a far better word to employ; because it conveys, physiologically, a truer conception of the way in which nature carries on her work in the vegetable kingdom. Every man of science knows that the vegetable processes are incorporated with the animal, in the animal kingdom; and if we study the latter carefully, we find that in every animal body a function is performed strictly analogous to the circulation of the sap. If we regard, as indeed we may, the animal stomach as the "root," corresponding with that of the plant, we find that the proper function of that organ is to receive the crude materials of food, of whatever kind it may be, and to convert its nutritive elements into "chyle," which is simply "animal sap," and which, by means of suitable vessels, is conveyed into the current of the blood to augment the permanent stock of that tissue-making fluid. Now, this is precisely similar to what we find in the vegetable world; and to pursue the analogy, if we follow the course of this "animal sap or blood," through the arterial system of vessels which convey it to the tissues it is destined to repair and nourish; we come to a system of vessels more and more minute until we reach what are termed the "capillaries," vessels so minute as to resemble in calibre the merest threads, scarcely visible to the naked eye unless injected. Now, do we find here anything like "a suctional power" in operation? I think not. What we do find is precisely what we have in the leaves and tissues of the plant—a power of "assimilation," a kind of digestive process, by which, through the mysterious agency of the vital principle, the sap or plant food, brought up by the *vis à tergo*, described in my former letter, comes into contact with the absorbent vessels of the vegetable structures, and is, by their action, obliged to yield up its nutritive qualities, so necessary to the development of the buds, leaves, and other plant organs. This is just what goes on in the tissues of our own bodies, and though the process is a vital one, and, therefore, not easily comprehended, I think your readers will agree with me that "assimilation" is a better word to use than "suction," in order to convey the precise nature of the function performed, whether in the animal or vegetable kingdoms. In both cases the food is conveyed to the tissues, and in both an appetite, if I may use the term, exists for it, and if "A. M." will kindly substitute "assimilation" or "absorption" for the word "suction," in reference to that appetite; and "excretion" or "exudation" in lieu of "pumping," in reference to the evaporative process and the mode of ascent of the sap, his views and mine will be found to correspond pretty closely. But I repeat that there is nothing in the vegetable economy that exhibits the property of expansion and contraction involved in the idea of "pumping," and such as we do find in the animal body, represented by that wonderful pump termed the heart, and that complex system of arteries whose systole and diastole assist so efficiently in propelling the current of the blood. From the foregoing remarks, it is clear that I am misunderstood by your correspondent "A. M.," who seems to think that I regarded the process by which a plant is nourished as mechanical, whereas I only applied the idea of mechanism to the mode of the ascent of the sap. My unwillingness to trespass upon your space prevented me from offering, at that time, the fuller theory above rudely sketched; but I hope yet with sufficient distinctness to aid, in some degree, in clearing up the difficulties which beset this interesting subject.

I may remark that the experiment with the twig mentioned by "A. M." does not in any way conflict with my theory of plant circulation and nourishment. The fact of the colouring matter finding its way upward in the twig, after severation from the plant, only shows what we knew to be a peculiarity of all plants, that the vital power is not destroyed by that severation, and that the plant

functions go on, only perhaps in a less active manner than ordinary, under such circumstances. If this were not so, the trade in "cuttings" would not be the thriving one it is. In the animal kingdom this capacity of retaining life in a detached member is at its minimum; it increases as we descend to the lower beings of the animal scale; and when we come to the vegetable kingdom, we find this remarkable power of self-existence in sundered parts at its maximum degree; so much so that in many instances every bud may be regarded as a distinct plant, capable of a separate existence when detached from the parent stem. Assuming then that the severed twig is placed in coloured water, it is evident from the experiment referred to by "A. M." that the freshly-cut stump can perform the function of a root, not quite naturally, however, in this case, because here the only function that can go on—the supply of sap being cut off—is the absorption of the coloured water, by capillary attraction, through the wounded vessels of the plant. A twig would not often survive long under such circumstances; but place it in soil, or in other favourable conditions, and roots will spring from the stump, and the formation of sap will be resumed. It may be said that capillary action would not explain the ascent of the coloured fluid, because the sap being cut off, there is a stationary condition of the sap remaining in the twig after separation from the plant, which would prevent such action from taking place. But a little reflection will show that so long as the vital principle remains in the twig circulation must go on in its tissues; that is, if there is any fluid to be circulated and within reach. Stop all circulation and the twig must die; but place it in water, coloured or not, and circulation will go on, because the vital principle, still dwelling in the tissues, leaves, &c., the latter still perform their functions of absorption, secretion, and evaporation, and this wear and tear necessitates a supply of nourishment, which is conveyed upwards, by capillary action in the first instance, and subsequently, if the twig be planted and struck, by the ordinary action of the newly-formed roots. "A. M." asserts that the "sap" must continue to rise in the severed twig, because the coloured liquid rises; but how can this be assumed when there is no source left for sap to come from? for to assume that sap is formed from the water, in the absence of roots, would be a far-fetched idea.

To make my meaning quite clear, we have, I may say, two distinct mechanical agencies engaged in carrying on the circulation of the sap:—1st. The mechanical expansion, due to the exudation of sap from root action, causing the ascent of the sap in the larger vessels, by supplies constantly added from below. 2nd. The mechanical process, familiarly known as "capillary attraction," which commences at the points where the former agency ceases to operate, and which is limited to the more minute vessels, which convey the sap directly to its ultimate *points d'appui*, where the assimilating function is effected. If this capillary attraction be what "A. M." terms suction, there is nothing new in the theory, for this peculiar agency has long since been described by botanists as a cause of the upward sap movement. I am quite aware of the large evaporation from the leaves of plants mentioned by "A. M.," and agree in all he says as to the important purpose which this function fulfils; one analogous to the perspiratory action of the skin of animals—viz., an outlet for the waste matter of the vegetable economy. I do not, however, see in this function of the leaves anything resembling suction. They both absorb and excrete like the animal skin; and upon the healthy performance of the excreting process very much depends, because it is obvious that, unless there is a free transpiration from the leaves, the ascent of the sap must be obstructed; whilst, on the other hand, its due performance systematically empties the plant vessels through which the sap must ascend mechanically, as explained in my former communication. No doubt, as "A. M." remarks, Nature's processes are very complicated, and she never works by "single action." In plant action, a variety of mechanical, chemical, and vital processes are working harmoniously towards a common purpose. Human thought and experiment may, indeed, attain to an approximate view of the truth in relation to the facts which those instruments bring within the scope of our intellectual vision; but all that we can hope for in this discussion is that we may, by mutual help, endeavour to place those facts in true scientific position and relationship, so as to produce a theory that will harmonise with our knowledge and at the same time satisfy the requirements of scientific observation.

Dublin, March 3, 1873.

ROBERT M. CHAMNEY.

### CONIFER AVENUES AND OLD YEWS.

In making an avenue of Pines, what distance apart should they be planted, i. e., whether should they be set thickly at first, or placed at the intervals at which they are to remain? The latter plan would take fewer plants, but they might not grow so well. Also, do you know any way of arresting decay in Yew trees, on which the foliage

is becoming brown here and there? They have been transplanted upwards of two years, and have hitherto looked very healthy. Some of them are twenty years old.

J. S. G.

*Tyrone.*

[In making an avenue of Pines, I wish your correspondent had been a little more explicit, and had stated what variety or varieties he proposed to plant, and what length and breadth he proposed to make his avenue; also some data as to the quality of the soil, and whether the situation is exposed or sheltered. In forming an avenue of Pines, supposing such free-growing and beautiful varieties as the *Picea nobilis* or *Abies Douglasii* are to be used, I would plant about 10 feet apart, if the soil is good; much will also depend on the situation, whether sheltered or exposed, and whether they will ever become fully developed. If all conditions are favourable, and the avenue is of moderate proportions, the distance just indicated will suit very well for the larger growing species of Coniferous trees. The second sized species, such as *Abies orientalis*, *Cupressus macrocarpa*, *Abies Pinsapo*, &c., may be planted at 25 to 30 feet asunder. As to whether the trees are to be planted thickly at first or placed at the intervals at which they are to remain, I would advise planting them at once in their permanent places, and filling up the vacant spaces with common trees to act as nurses; or if appearances require it, plant up with quick-growing shrubs, such as Portugal Laurel or common Bay, to be thinned out gradually as the avenue trees fill up the ground. As regards arresting decay in Yew trees in which the foliage is becoming brown here and there, I have frequently seen Yew trees with the foliage in that condition, when growing in poor, light, gravelly loam on a dry gravelly sub-soil. In this case the remedy is top-dressing with rich compost; to deepen and enrich the soil; for all, or nearly all coniferous trees, like a moderately rich soil to grow in, either naturally or made so artificially. I have used thousands of cart-loads of decayed vegetable matter for this purpose, the effects of which were visible in a few months after its application, the yellow tinge of the foliage giving place to a fine rich green. Removing the soil near the roots and replacing it with a good strong loam, in which the Yew tree delights, will answer the same purpose and be more permanent in its effects; but this is a somewhat expensive process, and can only be judiciously recommended where a few favourite specimens are to be operated on. In strong stiff soils imperfect drainage often causes Yew trees to have an unhealthy appearance. If the subsoil is formed of clay or other substance very retentive of moisture and not thoroughly drained, or even if the drainage is pretty good, if the pits to receive the trees when being transplanted were formed in wet weather, and much trampled, a puddle is formed which will effectually hold water, and the almost unprecedentedly large rainfall of last season would aggravate the evil and keep up a supply of stagnant water around the roots, which would account for the unhealthy appearance of the trees; a drain carried from each pit would remedy this defect.—

ARCHD. FOWLER, *Castle Kennedy, Stranraer.*]

## GARDEN DESIGN.

### THE NEW ROCK-WORK IN BATTERSEA PARK.

This is the first attempt at making a really picturesque rock-work that has been carried out in any London Park. Considered as such, its effect is very good indeed, and the imitation of natural rock very happy, as might be expected when we state that it was executed by Mr. Pullham, of Brompton, who has made most of the really effective rock gardens in the country. Our illustration shows rather a close view of the portion of the rock-work near the cascade; the general effect of the whole, as seen from the other side of the lake, is very different and very satisfactory of its kind. As yet the rocks are not sufficiently covered or garnished with vegetation to present the best effect, but already their appearance is highly satisfactory. This rock-garden is not one prepared specially for rock-plants, but rather for its picturesque effect in the park. It is easy, however, to group rock-plants on the slopes of earth near the large masses of artificial rock, and this has already been done to some extent. In one part we were glad to notice that the excellent opportunities which such large rocks offer for the display of the glorious new Clematises had been taken advantage of. Our illustration of this rock-garden, drawn by Mr. Justyne and engraved by Mr. Cooper, is, we believe, the first ever published which gives a worthy idea of a rock-garden on a large scale which is really worthy of imitation. Such examples cannot fail to have the best effect on the gardening design of the future.

THE ROCK-WORK IN HATFIELD PARK.

## THE FLOWER GARDEN.

### LILY OF THE VALLEY.

THE present being a very good time to make new plantations of this Lily, select a good piece of ground for the purpose, manure it well, and then trench it 3 feet deep. If stiff land add to it plenty of coarse sand or leaf-mould, ashes, or mortar rubbish. The crowns should be singled out to one eye, and all superfluous runners should be cut away, leaving the roots only. If single eyes are chosen, plant them in rows 2 inches apart, keeping the crowns well up to the surface, and cover with a little sand or any similar light coarse material. If clumps are wanted, take eight or ten eyes, place them in a bunch carefully, and tie a piece of matting round them; then plant them in the form of a triangle, a foot apart and the same distance asunder row from row, placing a handful of sand on each bunch, so that the rains may wash it down amongst the roots, leaving the eyes above ground. If well watered during dry weather, these clumps make fine material for forcing the second year. They should always be covered up with moss or cocoa-nut fibre when put into heat for early flowering, and kept damp, to get them well furnished with leaves. Should any flowering crowns be found amongst the stock at planting time, take them out and place twenty-four of them in a 6-inch pot; put them into heat, covering them up until they begin to break; then remove the covering, and put them in a warm light place, giving them plenty of water. Single crowns flag much sooner than clumps if cut or set in a draughty cold place. It is never necessary to keep Lilies of the Valley established in pots as, when forced, they do not root until after they have flowered. I take up mine as they are wanted, and place them in a pit, covering them up with leaves or moss, and giving them a good watering. I afterwards keep them wet, and pot them as they are coming into flower.

Bulham.

W. HOWARD.

### CHRISTMAS ROSES.

FLOWERS at the close of the old and beginning of the new year, even under glass, are by no means abundant, but abundantly precious, owing to the demand for them at that festive season, and the utter disproportion that exists between supply and demand. Few but are then made to feel the pressure and the pinch, and many with limited means are often regretfully obliged to denude their plant-houses of even the ghost of a flower. To obviate the necessity for this, it would be very agreeable if the cultivator could look outside his stove and conservatory, and have at hand some hardy helps which would enable him to tide over the difficulty. But, nonsense, the reader will perhaps exclaim—outdoor flowers in January! What are the plants or where are they to be had hardy and venturesome enough to put forth flowers at this, the most inclement period of the year? Well, it is no dream; such plants are the Christmas Roses or Hellebores, several of which are common enough, and there need be little difficulty about procuring any of the less common species, if desired. Everybody is familiar with the Christmas Rose, (*Helleborus niger*), which, commencing to flower about the time of the festival from which it derives its name, continues to bloom far into the new year. Well established masses of this are most effective when in flower, and we need not hint as to how useful its snowy blossoms are for the decoration of the drawing-room or the dinner-table. There is also a variety of this species—*H. n. grandiflorus*—with flowers much larger, of a purer white, and in every way more desirable than the species itself. This is the first to flower, and perhaps the next is *H. purpurascens*; its flowers, livid and lowly, which raise their heads barely above the soil, are not very striking. *H. atrorubens* and *H. olympicus*, with dark purplish flowers, succeed; these are followed by the finest, to our mind, of all—*H. orientalis*; its bold habit and profusion of large white flowers elevated on tall footstalks fully entitling it to be regarded, even apart from the season at which it flowers, as one of the finest and most telling border plants in cultivation. There are many other showy and desirable species, but as yet comparatively scarce. Of these, *H. kamtschatensis* is one. It is a white flowered species, in appearance and habit similar to the common Christmas Rose, but, to our mind, much superior. *H. colchicus* is one of the most beautiful of the red-flowered species; and then there are *H. chinensis*, *H. odoratus*, *H. vernalis*, and others. Now, besides the value of these Hellebores for affording cut flowers at a time when they are at a premium, they are also well calculated to

play an imposing part in the winter and early spring garden. For instance, would not a small circular bed, in a sheltered spot, planted with some half dozen sorts, be pretty and effective at a time when all around is dull and flowerless? It might be planted in this way—say a mass of the tall white *H. orientalis* in the centre, then a band of the dark reddish purple *H. atrorubens*, followed by another of the white *H. niger* or *H. kamtschatensis*, next a ring of the low-growing *H. purpurascens*, the whole finished off with a golden circlet of the bright little Winter Aconite (*Eranthis hyemalis*). In lines, or dotted and graduated after the same fashion in the dressed and sheltered shrubby border, an excellent effect might be produced. The Hellebores are the earliest of hardy flowering plants; in fact, some of them are going out of flower before what has been poetically, but incorrectly, termed, “the first pale blossom of the unripened year”—the Snowdrop, ventures to expose its hardy petals to the nipping blast. All the species are perfectly hardy, all free growers, and of the easiest cultivation, thriving in almost any soil or situation, but best where they are somewhat sheltered and partially shaded. They are increased from seeds or by division of the roots, and will grow and flower in partially shaded and sheltered situations in most parts of the country.—*Irish Farmers' Gazette*.

### THE SWEET-SCENTED POND-WEED.

(*AFONOGETON DISTACHYON*.)

OBSERVING Mr. M'Nab's valuable remarks upon this highly interesting plant, we may, for the encouragement of aquatic plant cultivators, state that we have found the plant to thrive and bloom well in our comparatively small pond at a depth of about 2 feet, and occasionally a little more, the centre depth of the pond running down to 4 feet. The floor is paved with bricks, without any contiguity with under-springs, the required consumption of water being supplied from public works. In the majority of instances we think that the failures that occur as regards the establishment of the plant are to be attributed to its being planted in too shallow streams, within the influence of frost, where it naturally gets “starved out” on account of its undue proximity to the cold surface water-flow. The flower-scapes of this species have been known to rise from between 2 and 3 feet in depth to the water surface—showing a wise provision in its structure for preservation when removed to a colder climate than its native one, and illustrating an important fact in vegetable physiology, that plants capable of forming roots at a great depth offer a stronger resistance to extremes of temperature than those whose roots are near the surface, as the temperature of the soil or water varies less in proportion to its depth. Though there are instances of the plant growing luxuriantly in still waters of a given depth, yet we would not commend a less depth than from 12 to 18 inches below the water surface. Being a native of the Cape, and a tuberous-rooted plant, it generally seeks a brief period of rest during our hot summer months, and again appears in vigorous growth during the spring, early summer, and autumn. Established plants produce flowers in succession for several months. In the conservatory, this fragrant and charming water plant may be grown, in deep pots or vases, with other miniature aquatics, plunged in water from 1½ to 2 feet in depth. For obtaining a succession of bloom in winter, a few strong reserve plants should have a partial rest late in summer, previous to being placed in a conservatory or stove for a gradual stimulus by the aid of a tank or bark bed. Pulverised turfy loam, with a fourth part of heath mould, is suited to its growth.

E. G. HENDERSON AND SON.

### THE WATER CHESTNUT.

(*TRAPA NATANS*.)

THE very singular four-horned fruits of this *Trapa*, which was the only one formerly known, have been compared to the spiked iron instruments called caltrops, employed in ancient warfare for strewn on the ground to impede the progress of cavalry; and, from the plant growing in water, it is sometimes called the Water Caltrops. Its flowers have a four-parted calyx with the tube adhering to the ovary; four petals, and as many stamens; and a two-celled ovary, with a cylindrical style and hemispherical flat-headed stigma. After flowering, the lobes of the calyx harden and form two or four more or less conspicuous horns at the top of the fruit; the latter being one-celled, hard, and unopening, and containing a solitary large pendulous seed, with very unequal cotyledons. Besides the European species, there are five or six others, natives of India, China, and Japan. All are floating plants, with long-jointed rootstalks, having tufts of hair-like roots (sometimes regarded as submerged leaves) at the joints, and surmounted by a

radiating cluster of triangular toothed leaves, with swollen float-like stalks, which serve to buoy them up.

The seeds of all these plants abound in starch, and are much eaten as food. Those of *T. natans*—called Jesuit's nuts at Venice, and Chataigne d'Eau by the French—are ground into flour and made into bread in some parts of Southern Europe. In Kashmir those of *T. bispinosa*, the Singhara of the natives, feed 30,000 persons for five months in the year, and are so extensively collected that the celebrated Runjeet Singh, of Lahore, derived a revenue of £12,000 per annum from them. *T. bicornis*, the Ling of the Chinese, has a fruit like a bull's head; the seeds of this plant also form a considerable article of food.

The Chinese mode of gathering this description of food is thus described by Fortune:—Leaving the old town (Kea-hing-foo, in the great Hang-chow silk district) behind us, and sailing westward, we entered a broad sheet of water of considerable size, which is probably part of, or at least joins, the celebrated Tai-ho lake. The water is very shallow, and a great part of it is covered with the *Trapa bicornis*—a plant called Ling by the Chinese. It produces a fruit of a very peculiar shape, resembling the head and horns of a bullock, and is highly esteemed in all parts of the empire. I have seen three distinct species or varieties, one of which has fruit of a beautiful red colour. Women and boys were sailing about on all parts of the lake, in tubs of the same size and form as our common washing-tubs, gathering the fruit of the

*Trapa natans.*

Ling. I don't know of any contrivance which would have answered their purpose better than these rude tubs, for they held the fruit as it was gathered as well as the gatherer, and at the same time were easily propelled through the masses of Ling without doing the plants any injury. The sight of a number of people swimming about on the lake, each in his tub (see p. 214), had something very ludicrous about it.

To get the horny-looking seeds of this plant to germinate in this country, it is necessary that the water in which they are placed should range in temperature between 60° and 80° Fahr. After germination the plants grow quickly, and soon show their pretty roundish floating leaves over the surface of the water. They thrive best in a house intermediate between an ordinary stove and greenhouse while they are young, but as they advance and the weather out-of-doors gets warmer, they may be safely removed to any pond or tank where the water is not impure. In this way the plants continue more healthy, flower better, and ripen their seeds with more certainty than they do when kept in a warm house. At Glasnevin *Trapa natans* is cultivated in a small pond or rather tank outside the Victoria Regia house, which has a pipe of 2 inch bore, connecting it with the Water Lily pond inside the house. When the latter overflows, the heated water is received into the small tank outside, by which means the temperature of the water is considerably increased. Under this treatment the *Trapa* grows vigorously, and ripens seeds annually, which are allowed to fall to the bottom and to remain

there during the winter. After the Water Lily house is put 'to work' in April, the *Trapa* soon appears in the outside tank, and spreads rapidly over the surface of the water. This tank is simply built with bricks and cement, and is about 15 feet long by 6 feet wide. It gets no heat during winter, and is frequently frozen over, yet a number of half-hardy aquatics thrive well in it, such as *Limncharis Humboldtii*, *Pontederia cordata*, *Sagittaria obtusifolia*, &c. *Nymphaea gigantea* and *Nelumbium luteum* have both flowered well in it during the summer, but they perish if not removed to warmer quarters in winter.

D. M.

## HARDY FOREIGN FERNS.

(Continued from p. 125.)

**Adiantum pedatum.**—This is a noble deciduous species from North America, and one which no collection of Ferns, however small, should be without; the fronds are pedate and spreading, supported upon jet black erect stems; the pinnae are numerous and of a vivid green, rendering it at once a most conspicuous and beautiful object.

**Athyrium Goringianum pictum.**—A near relative of the Lady Fern of our woods, producing long, pendulous, somewhat lanceolate fronds, the ground colour of which is dark green, but the rachis is deep red, having a greyish band on each side, giving it a distinct and handsome appearance. It comes from Japan.

**Botrychium virginicum.**—This plant is common throughout the United States of America as well as in Canada, where it is called the Rattlesnake Fern. The fronds are dark green, bipinnately or tripinnately compound, when fertile, producing, in addition and separately, numerous little spikes of bell-like sori. This plant thrives best in a well-drained position, and during winter it should have some litter strewn over and about its crown and roots.

**Botrychium lunarioides.**—In general appearance this resembles *B. virginicum*, but the segments of its dark green fronds are quite oblique, and of greater substance than those of that species; it should be treated in the same manner as *B. virginicum*. It is a native of North America.

**Cyrtomium falcatum.**—This is a grand and distinct plant for the open-air fernery, where, however, it frequently becomes deciduous, whilst, if grown indoors, it is evergreen; the crown is densely clothed with large dark brown chafy scales, from which the pinnate fronds rise and attain a length of from one to two feet; the pinnae are some six inches long, elliptic, lanceolate in shape, and dark shining green in colour. It is a native of China and Japan.

**Cystopteris bulbifera.**—This beautiful species grows from 12 to 18 inches in length, the fronds being bipinnate and deeply incised, the colour pale green. It forms a quantity of bulbules on the lower side—a property which has given rise to its name; these fall off when the fronds are mature, take root, and soon form a nice mass on the rockwork. It is a native of North America, and has been long in this country.

**Cystopteris tenuis.**—This beautiful kind is also a native of North America, and should be planted in the most shady portion of the rockery, in order to keep it from starting prematurely into growth. The fronds are ovate-lanceolate in shape, bipinnate; when strong, 9 inches high, and deep green in colour.

**Dictyogramma japonica.**—An erect, bold-growing Japanese Fern of great beauty and interest, known perhaps better to some by the name of the hardy *Gymnogramma*. It differs, however, from *Gymnogramma*, in having netted veins. It usually grows about 2 feet high, the fronds are pinnate, frequently bipinnate at the lower part, pinnae some 8 or 9 inches long, lanceolate in shape, and dark green. The large entire pinnae, which are beautifully reticulated with the sori, render it a distinct and handsome plant, forming a striking and pleasing contrast to those species with finely-cut fronds.

**Lastrea varia.**—This is a fine, robust-growing plant, to be found in some collections under the name of *L. opaca*. The fronds vary from 1 to 2 feet in length, and are broad and much divided; the colour is a very dark shining green, the large jet black sori being an additional ornament to this fine species. It is a native of Japan and China.

**Lastrea erythrosora.**—This is also a fine species, producing broad bipinnate light green fronds, which vary from 1 to 2 feet in length. The sori are large, and, when young, covered with a bright red indusium, forming a very handsome and distinct feature. It is a native of Japan.

**Lastrea Sieboldii.**—A fine bold Japanese plant, the fronds of

which are usually about 18 inches long, pinnate and dark green; the pinnae are large, being some 6 inches long by 1 inch broad, bearing on the under side a profusion of very dark brown sori. It is a most distinct and desirable plant.

**Lastrea hirtipes.**—This plant requires a little protection during winter. The fronds are erect, some 2 feet long, pinnate, and somewhat narrow for their length; pinnae serrate at the margins, and dark green in colour; the sori are very large, whilst the stipes are densely clothed with black hair-like scales. It is a native of Northern India.

**Lomaria alpina.**—This is a dwarf dense-growing New Zealand species, the barren fronds of which are broadly lanceolate, pinnate, about 6 inches long, and very deep green; the fertile ones are about the same length but not half the width; it is perfectly hardy, and a most desirable plant.

**Lomaria chilensis.**—This noble Fern seems to have become exceedingly scarce, a circumstance much to be regretted, for it is undoubtedly one of the finest of all Ferns for the open-air Fernery; the fronds are from 2 to 6 feet in length, according to the treatment received, and are beautifully curved; they are pinnate, bearing many pairs of large, entire, very dark green pinnae; the fertile fronds are also pinnate, but much contracted. It is a native of Chili.

**Lygodium palmatum.**—This is a singular plant, which all lovers of Ferns should cultivate. It is the hardy representative of a genus of climbing Ferns, all of which are very handsome; and although this particular species seldom exceeds 2 feet in length, it is most interesting; the fronds are palmate; sometimes three-lobed, but frequently five-lobed; the upper portion is usually fertile and contracted. In exposed situations a little litter should always be scattered over this species during winter. It is a native of North America.—*Villa Gardner.*

### PRUNING ROSES.

ONE of the most important operations requiring attention in the Rose garden during March is that of pruning. Some growers have expressed an opinion that November is a good time for pruning Roses, but the greater number recommend it to be done in February. I am altogether opposed to the system of autumnal pruning; and, although I will not go so far as to assert that February is too early in all seasons, I am strongly of opinion that March is quite soon enough for hardy sorts, and too soon for Chinas. By hardy Roses I mean the whole tribe of summer bloomers, generally comprised under the divisions of moss, Provence, hybrid Provence, French, damask, alba, hybrid China, hybrid Bourbon, hybrid Noisette (a distinct section, although not generally recognised), Austrian Briar, Sweet Briar, Scotch, and the several families of climbing Roses. Of autumnal bloomers the perpetual moss, damask perpetual, hybrid perpetual, and Bourbon families must be included in the category of hardy Roses. Shall any especial order be observed in pruning these different sorts, or shall they be taken hap-hazard? I have seen it laid down in books that the moss, Provence, French, alba, damask, and Austrian Briars should be first pruned; then the hybrid China and hybrid Bourbon, and next the damask perpetual, hybrid perpetual, perpetual moss, and Bourbon. Now I beg to differ from this view of the case. I recommend, whether large or small, to apportion the plants in three equal parts, taking care that the different families are fairly distributed among the whole, and to have three great prunings—namely, at the beginning, the middle, and the end of March. Rose pruning is of three kinds, viz., close pruning, long pruning, and moderate pruning. The first method is applicable to all such Roses as are of dwarf habit and compact growth, producing shoots on which the bloom-buds are closely set. In this list may be included the families of moss, Provence, Gallica, alba, damask, and Austrian Roses. All these require close pruning; that is, the shoots should be cut back to within an inch or two of the old wood, leaving only two or three buds at the base. Long pruning must be used for such sorts as are very vigorous growers; many of these produce shoots from six to ten feet long, and if these were subjected to the close system of pruning, not a flower would be produced. The sorts requiring long pruning include nearly all the hybrid China, some of the hybrid Bourbon, the more vigorous among the Bourbon, and a large proportion of the

Noisette tribes. In all these the shoots must be well thinned, taking care to remove those likely to militate against the production of a handsome symmetrical head; the remaining shoots must be shortened to a foot or eighteen inches, according to the habit of the plant. There are a few of the hybrid Chinas in which it is necessary to leave the shoots nearly their entire length, merely removing a few inches of their extremities; of sorts requiring this treatment, the five old varieties, Beauty of Billiard, Brennus, and Fulgens are examples. In the course of a few years Roses thus treated will become straggling and unsightly; when this occurs they must be cut back to within an inch or two of the crown, when fresh buds will push and a new head be formed. If this is done immediately after the plant has bloomed, there will, in ordinary summers, be plenty of time for the new wood to mature itself, and thus the loss of one season's bloom will be avoided. If the wounds are immediately covered with some styptic, there will be no bleeding; otherwise the plant might be much exhausted, if not actually killed, by the loss of its juices. Moderate pruning is a sort of compromise between the other two methods. It consists in shortening the shoots to within six or seven inches of the old wood, and is the form of pruning best suited to the more robust-growing varieties of French, damask, and hybrid Provence Roses, the most vigorous of the hybrid Chinas and hybrid Bourbons, and those of medium growth among the Bourbons and hybrid perpetuals. The pruning of the China and tea-scented Roses, together with such of the Noisettes as claim affinity with them, should be deferred until April.—R. D.

### SEDUMS AND SAXIFRAGES.

It is satisfactory to perceive that plants belonging to these and kindred genera are becoming better known and appreciated than they used to be. The marvel, indeed, is, that a tribe of plants containing some hundreds of species and varieties should have remained so long in obscurity as it has done, especially as among them may be found plants of every possible variety of form and every conceivable degree of beauty, from the most inviting green velvet-like cushion to the compact globular mass which, when in flower, looks like some miniature mountain beset with fairy gems. First there are the encrusted varieties—beautiful little rosette-looking things, glaucous or silvery in colour, so profusely fringed with pearls, that one is led to wonder whether they are plants or jewels. They are so variable in respect to habit, that while some kinds would soon cover with most beautiful green, rocks, quarries, scars, and similar places, others would almost grow in a thimble. A whole garden might, indeed, be made interesting with Saxifrages and Sedums alone, and it would have this advantage, that it would look equally beautiful in winter and summer. Do you want something cheerful to look at during the dead season of the year? Wander into the Saxifrage garden and contemplate the beautiful masses of emerald and pale green, and yellow green and blue green, that will meet you at every turn. Are you blinded with too much colour in the dog-days, "cool your eyes," not on "the Parsley bed," but on charming masses of sea-green Saxifrages. As to clothing and ornamenting rockwork, whether it be a miniature porch under a glass-shade, or hundreds of tons of granite, artistically put together, nothing can, nor ever will, equal Saxifrages. Sedums and Saxifrages, in short, are alike suitable for the smoky city and the open garden in the country. London Pride (*Saxifraga umbrosa*) and some others, such as *S. glacialis* and *cernua*, for instance, grow equally well in our great metropolis, and in the pure rarified air of mountain peaks and Alpine passes. Some, again, as *Saxifraga nivea*, live almost within the snow-line; others, as *S. Fortunei* and *japonica*, are at home in the temperate valleys of China and Japan; while *S. Icelandica* flourishes in the Arctic regions. My collection of these interesting plants is but a small one, but I trust that my partiality for them will enable me to point out their beauties, and their utility and adaptation for various decorative purposes.

### SAXIFRAGES.

These fortunately, considering the vastness of their numbers break themselves up into well-marked tribes or divisions, a circumstance which, while it adds to their diversity and beauty, greatly facilitates arrangement, both for pleasure and study. The first section which I shall notice is what may be termed the "mossy" or "hypnum" group. These consist of spreading carpet-like plants, such as *S. muscoides*, *Schraderi*, *glacialis*, and others; or of such as assume a more compact, round, cushion-like form, as *densa*, *tenella*, *virescens*, or *lavis*. Some belonging to this section assume a frosty or glaucous tint, as *Gmelini* and *palmata*. The plants included in

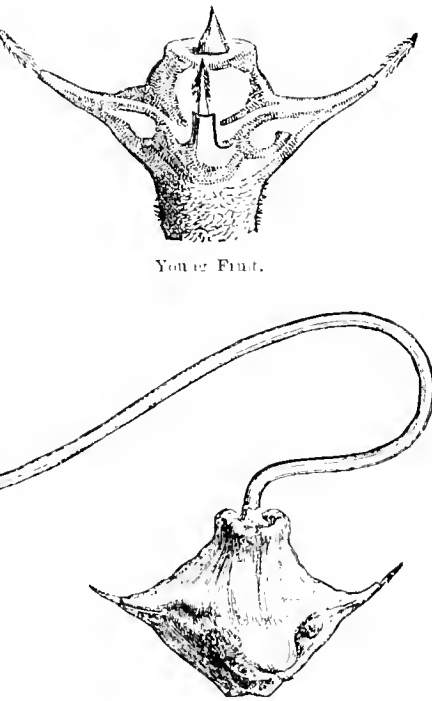

this section are, perhaps, more accommodating and useful for decorative purposes than those in any of the other divisions. Another small, but very effective group, is the Staghorn division, consisting as it does of compact masses, with rigid, leathery, much-divided foliage; this includes such sorts as *ceratophylla*. Another group, and one very unlike any of the others, both as regards foliage and flowers, is that of which "*oppositifolia*" may be taken as the type; of this there are four varieties, viz., *oppositifolia major*, *retusa*, *pallida*, and *alba*; masses of the latter, flowering in February or March, might be mistaken for snowdrifts. Perhaps, however, the most exquisite of the Saxifrages is the encrusted tribe, so called on account of the margins of the leaves, which are silvery, being studded and beaded with pearls. These include such sorts as *rosularis*, *intacta*, *intacta minor*, *pectinata*, *incrustata*, and others. So small is *intacta minor* that half a dozen plants of it might be grown in a watch-case. This section contains the very best of the Saxifrages, of which the most lovely species known is *S. longifolia*, a rare plant belonging to this section, and with which *S. lingua* has for a long time been confounded. Another group is the Strawberry group, of which the Wandering Jew (*S. sarmentosa*) may be taken as the type; *S. japonica variegata* also belonging to this group, is a startling plant when well coloured. To the *umbrosa*, or "London pride" group belong thick leathery, deeply-toothed plants, mostly with round or ovate leaves, such as those represented in the kinds called *reniformis* or *ovalifolia*. There is, too, a subdivision of this group, with deeply-toothed, elongated foliage, in which may be found such kinds as *Andrewsii*, *Guthriana*, and *dentata*, and lastly, there is a multitude of others, such as *tricuspidata*, *hieracifolia*, *asiatica*, and *granulata*, that do not associate with any one division.

It has already been hinted that a large rockery wholly decorated with Sedums and Saxifrages would have a pleasing effect, and so it has when kept in good order, i.e. when one kind is not allowed to overgrow its neighbours so as to destroy its individuality; for when several dozens of these plants are permitted to run together in the form of a sod, the rockery on which they grow becomes little better than a mound of turf. Damp, dirty, mortarless walls, even in backyards and courts in cities, may be made interesting by having bits of the various mossy Saxifrages thrust here and there into their chinks. Their deep green tufts have a charming effect every month in the year in places where even Ivy itself will scarcely live. The following twelve kinds are suitable for this purpose, viz., *Schraderi*, *muscoides*, *palmata*, *incurvata*, *virescens*, *leptophylla*, *elongata*, *tenella*, *glacialis*, *densa*, *lavis*, and *propendens*. Those who may not have walls such as those alluded to, may still enjoy these pretty little Saxifrages, by keeping them in a glazed frame of such dimensions as they may think proper, regarding sun as to them of no importance; such a case could be set in whatever place could be found for it; this would afford to its owner interesting recreation for every day in the year. The following twenty-four sorts would form a nice collection for a one-light frame, viz., *S. recta*, *Maylii*, *intermedia*, *densa*, *pulchella*, *Guthriana*, *capillaris*, *reniformis*, *Geum densa*, *pallida*, *Aizoon*, *aizoides*, *aspera*, *propendens*, *tricuspidata*, *ceratophylla*, *intacta*, *virescens*, *retusa*, *Bucklandii*, *umbrosa variegata*, *dahurica*, *dentata*, and *palmata*. These have all a fine compact habit, and great

diversity of form. These who would wish to have collections of Saxifrages and Sedums combined in one frame might add the following twelve of the latter, viz., *Sedum Sieboldii*, *Ewersii*, *pulchellum*, *hispanicum*, *acre variegatum album*, *dasyphyllum*, *Telephium variegatum*, *kamtschaticum*, *tenellum*, *stellatum*, and *teretifolium*. These would form a beautiful combination, and although all of them have a neat habit, yet they are all highly diversified as to form and colour.

Ferns have so long monopolised such contrivances as glass shades and cases, that it requires some degree of hardihood, even to hint that other plants may be found that are equally as interesting. Nevertheless, a case containing an assortment of miniature Saxifrages, Sedums, and perhaps *Sempervivums*, planted on miniature rockwork would be a charming object. The following twenty-four sorts are suitable for this purpose, and would thrive in the sunniest window—viz., *Saxifraga rosularis*, *longifolia*, *densa*, *Aizoon*, *intacta*, *incrustata*, *pallida*, *pectinata*, *juniperina*, *Andrewsii*, *umbrosa*, *dentata*, *virescens*, *glacialis*, *capillaris*, *umbrosa variegata*, *pulchella*, *tricuspidata*, *Bucklandii*; *Sedum graueum*, *grandifolium* (truly beautiful), *dasyphyllum*, *Ewersii*, *pruinatum*, and *spirale*. All these are beautiful in form, and possess much richness of colour, varying in hue from the emerald green of *Saxifraga densa* to the silvery tints of *Sedum dasyphyllum*. *Sedum grandifolium* has also prostrate, rosette-

looking, silvery tufts, the outer leaves being of a ruby red. Many of these never exceed the size of a crown-piece, and most of them may be kept within very small bounds. No twenty-four dissimilar Ferns could be grown in the same space as these, and it is questionable whether any other twenty-four truly hardy plants could be brought together that would live and thrive, and want so little attention and give so much satisfaction as these. The following twelve kinds are real gems amongst Saxifrages, and all of them may be grown on a bit of rockwork under a glass shade—viz., *Saxifraga Aizoon*, *Aizoon compacta*, *dahurica*, *longifolia*, *intacta*, *intacta minor*, *rosularis*, *pectinata*, *incrustata*, *retusa*, *densa*, *Guthriana* and *cuneifolia*. Rocks, ravines, scars, old quarries, and similar places, near drives, may be made highly interesting when planted with the cushion or fleecy Saxifrages. There are perhaps as many as thirty or forty sorts that would be suitable for this purpose. Many of our miniature Saxifrages are peculiarly adapted for delicate tracery or scroll-work, forming, as they may be made to do, lines or bands of green and silver or grey. The following are adapted for this purpose, viz.:—*S. capillaris*, *Guthriana*, *dahurica*, *umbrosa dentata*, *densa*, *Andrewsii*, green; *intacta*, *rosularis*, *angustifolia*, *pectinata*, *incrustata*, *recta*, silver. The chief use to which Saxifrages may be put, however, is the winter and spring decoration of flower beds, for which they are invaluable. It is a question whether a design, in the dead of winter, tastefully planted with Saxifrages, would not even surpass any amount of summer decoration that could be bestowed on it. Nothing in the way of evergreens, however compact, can equal a combination of these charming plants; prepared in spring or early summer in the reserve garden, they may be planted whenever wanted—July or Christmas. They are adapted for every size of bed, from 8 or 10 feet down to the smallest pin cushion.

*Trapa natans* and its fruit. (See p. 208.)

The following are a few combinations suitable for large beds, viz.:

—*Saxifraga lingua* edged or mingled with *densa*; *virescens* edged, with *Geum densa*; *palmata* and *hypnoides* edged with *recta*; *trispidata* edged with *Geum gracilis*; *geranioides* edged with *lingua*; *propendens* edged with *pulehella*.

Medium-sized beds may be planted as follows:—*ceratophylla* edged with *densa*; *serratifolia* edged with *capillaris*; *pulehella* edged with *Aizoon*; *tenella* edged with *Hostii*; *Geum densa* edged with *pallida*; *Gmelini* edged with *dahurica*.

For miniature beds the following are most suitable:—*Androsii* edged with *intacta*; *rosularis* edged with *densa*; *dahurica* edged with *pectinata*; *densa* edged with *inerustata*; *capillaris* with *intacta minor*; *pallida* with *rosularis*.

Though these lists contain but few kinds, yet, like the changes that may be rung on bells, the alterations that may be effected with them are endless.

THOS. WILLIAMS.

Bath Lodge, Ormskirk.

**Plants for a Steep Bank.**—If your correspondent, "A Country Parson," had told us in what county he resided, it would have been easier to help him. But Solomon's Seal (*Polygonatum*) will grow anywhere in England in such a place, near the bottom, if undisturbed at the root. The large *Periwinkle* (*Vinea major*) will do next above it, and make green tufts all winter. The *Forget-me-Not* (*Myosotis dissitiflora* and *alpestris*), alternated with *Eschscholtzia crocea*, allowed to seed themselves, and to cover their old stumps with crowns of their own dead leaves all winter, will look lovely from April to October (the *Myosotis alpestris* flowering a second time if the first heads are trimmed off about July). *Aubrietia purpurea* would edge the top, and tufts of variegated white *Alyssum* would look well against it. Several sorts of *Oxalis* like northerly banks, and so do *Snagdragons*. The latter should be raised from seed elsewhere, and continually shifted, so as to prevent their running too much to branching roots, which interfere with their flowering. They should be planted out on the bank to remain, about the end of September, and slightly protected (with bits of Bracken twisted about them) from severe frost. Irish and English *Ivies* would creep up the bank, but they are apt to kill other things. Nearly all the *Aspidium* (*Polystichum*) race of British Ferns, and the *Lomaria* spicant will do well there also. The chief rule is never to allow a gardener's ruthless spade near the bank after it is once well cleansed from weeds, and planted. Let the plants go their own way, and surface-weed by hand or small hooked spud only. Occasionally the surface should be loosened in dry weather with a small fork. Can your readers tell me, in return, why my *Ixias* and *Sparaxis* always come up green, and remain so all winter, and then die gradually away in spring, when they ought to send up flowers? The roots look healthy. This has happened four years in succession.—KING'S NORFOLK.

## NOTES AND QUESTIONS ON THE FLOWER GARDEN.

**Crocus veluchensis.**—This pretty purple species, from the mountains of Atofia, is now in bloom with me. It is closely allied to *C. vernus*. The petals are, however, much broader and blunter at the tip; the flower-stalk is much shorter and the sheath longer and broader. The flower appears when the leaves are only just showing. Near the outside tip of each petal there is a conspicuous blackish purple belt. It is a tender species.—H. HARPER CREWE, *The Rectory, Drayton Beauchamp, Tring, March 8.*

**The Sweet-scented Pond-weed** (*Aponogon distachyon*).—Mr. McNab, I think, must be mistaken in attributing the well-being of this aquatic in the Botanic Garden, Edinburgh, to the action of springs at its roots. I have seen it thrive well in ornamental water where the bottom and sides were cemented. In a pond in the gardens of Lord Portman, at Bryanston, this Pond-weed grows and blooms profusely, and often ripens seeds which produce hundreds of young plants. At Castle Ashby it is planted in pots that stand on the hard bottom of a circular pond, and even in that position it grows much more luxuriantly than in the deep mud of the fish ponds.—G. B.

**Cerastium Edgings.**—What is the best way of planting *Cerastium* bordering to beds on a lawn? Ought they to be renewed, or allowed to remain year after year? For two years we had a very effective edging kept cut, about 9 inches wide, but it has looked poor and irregular since, though weeded and slightly renewed. How am I to improve it?—U. J. P. N., *Raugh*. [Cut over your *Cerastium* edgings and lift the plants; dig the ground on which they grew, and add some leaf-mould to it; then divide the plants into little rooted tufts, and plant them about 3 inches apart. This should be done now, and the plants will soon form nice edgings, which should be renewed in this manner every second year.]

**The Gigantic Dog's-tooth Violet.**—*Erythronium giganteum* (Lindl.), *E. grandiflorum* (Pursh).—This fine addition to our hardy spring-flowering plants, when better known, will receive a general welcome. It bears several large and handsome flowers upon one stem. In very strong wild specimens as many as ten blossoms are found on single stalks, 1½ foot high. The colour is exceedingly variable—usually it is of a creamy-white, delicately shaded with pink or purple. Some are white, others lemon-coloured, and others again deep red-purple. It remains, however, yet to be ascertained whether two or three "forms" inhabiting large and widely spread regions may not eventually prove to be specifically distinct from each other. The flowers of *E. giganteum* are individually 3 inches across, and the petals broad. Its leaves are very richly and heavily marbled with purplish brown.—B.

## PUBLIC GARDENS.

### THE ROYAL GARDENS, KEW.

BY PROFESSOR OWEN.

You have shown your interest in the "Kew Question," by admitting the "Statement" in which I gave reasons for the space assigned in my "Plans for a Museum of Natural History," on the assumption that the National Herbarium would continue to be maintained in the metropolis, and by giving Dr. Hooker's "Reply" to that statement. I, therefore, trespass upon you with remarks thereon, especially upon the strongest, if not sole, ground which the Director has urged upon the administration for having the "first-rate herbarium" at Kew Gardens.

This ground is an appeal to the increase of the plants new to science at Kew since the time when the naming of such was done in London, and an estimate of the latter metropolitan work, which work had appeared to me to afford some ground for thinking it might have been, and still might be, continued to be done in London.

The naming of plants growing in a botanical garden is the work of the nomenclative botanist. To determine the species received there, which may be unknown to the physiological botanist in charge of the living plants, requires their comparison, or that of their characteristic parts, with the dried specimens in a herbarium. For this end the more complete the herbarium the better is it for the purpose. To deposit the specimens collected in Australia or in the vicinity of the Congo, at a given period, in one museum, and the specimens there collected at a subsequent period in another museum, detracts from the utility of both. The National Herbarium ought to be "one and indivisible." Administrative wisdom will not much longer endure two competing museums carrying on their competition at the public cost.

Dr. Hooker contends that his museum is needed at Kew for "keeping accurately named public collections that occupy 300 acres and are estimated to contain 20,000 species."†

Admitting, as a logical but non-botanical statesman would do, from the relation of this avowal to my argument, that the plants of 20,000 species growing on such an acreage might call upon the director of the gardens to consult a herbarium for the name of each, and that the like labour might be imposed upon him in order to name the additional "literally thousands of plants from other botanic gardens and nurseries in England and similar institutions abroad,"‡ transmitted to Kew for that purpose,—even then a large-minded administrator might take into consideration the question whether the interests of all other students, British and foreign, of a National Herbarium need be, or ought to be, sacrificed to the personal convenience of the director of the Royal Gardens—whether it were administratively wise or just to adopt a recommendation "compelling the resort of all botanists to Kew."||

Every botanist knows that the statesman would have drawn an erroneous inference from the director's "Reply." The facts for his chief's guidance were the number annually of species new to science which were, in such years, growing at Kew, and which there first received their specific names, a list of which might have been advantageously appended. To substitute for this important "constant," vague statements of "twenty thousand," and "literally thousands of plants" growing at, or brought to, Kew, and wanting names, with the acreage of ground liberally added for the pleasure of the public to the Royal Gardens, was not the information required for right judgment on the point at issue, nor such as was calculated to increase the Minister's estimate of the worth of a "Report."

To the argument which it was my duty to submit in favour of a continuance of the one great herbarium in the locality adopted for it by the State before the successors of the Aitons began to develop their competing collections of dead plants at Kew, viz., the application of such herbarium to the "naming" requirements of the Aitons, Dr. Hooker contrasts his statement of nomenclative work, above adverted to, with what he defines as the "naming of a few and rare plants cultivated at the beginning of the century in a private garden of nine acres, probably at no time containing more than 1,000 species."¶

The Royal Gardens at Kew were developed for the service of botany. His Majesty King George III. called to his councils, for the

realization of this wise and beneficial resolve, Sir Joseph Banks.\* The number of new species brought home by Banks and Solander strengthened the royal resolve, if their collections of living plants from Cook's circumnavigatory voyage did not initiate the "Royal Gardens." Of these the development was rapid, under the auspices of Banks and the able gardeners whom he recommended, aided by the Banksian Herbarium, and the nomenclative botanists he placed in charge thereof. So developed, the Royal Gardens were freely open to the visits and uses of botanists. It is part of the history of the science.

In the dedication to the King of the "*Hortus Kewensis*," Aiton defines it as:—"A work rendered necessary to the public, not only by the number of valuable plants continually sent home by your Majesty's collectors abroad, but also by the extensive influx of curious exotics poured into it of late by your Majesty's subjects, anxious to aid, by their individual exertions, that magnificent patronage which has rendered Botany a favourite pursuit among all classes."† This definition of the "Royal Gardens" as they existed in 1813, continued to be applicable up to the period when they were formally, as heretofore they had been virtually, in relation to botanical science, "Public Gardens." I submit that to define, in an official statement, the scene and sphere of the labours of his predecessors as a mere "private garden" is a rhetorical artifice unworthy of a successor of the Aitons and of the important administrative question at issue.

Next, as to the avowment of "the few and rare plants" in this garden, "probably at no time containing more than 4,000 species."‡ Aiton, in the second edition of the "*Hortus Kewensis*" (1813), gives the number at 9,800 species. John Smith, curator of the same garden up to 1864, writes:—"About 13,000 species had been noted as contained in the gardens, but the greatest number at any time was 11,000 species."§ But the numbers, like the 20,000 species of Dr. Hooker, are outside the question which is truly touched by statements yet to be given of the percentage of species new to science requiring a continuance of the herbarian comparisons for their determination. Respecting which work, so truly and touchingly acknowledged by the younger Aiton, I regret to be compelled to remark, that, to stigmatise the "Botanical Works" devoted to the determination of the new species of plants in the "Royal Gardens" as a mere "naming of a few and rare plants cultivated at the beginning of the century"¶ is excusable on the sole plea of ignorance, and could not, I think, be hazarded by any botanist cognizant of, and capable of appreciating, the brilliant period of the history of his science during which the Banksian herbarium was applied to the nomenclative needs of the Royal Gardens at Kew.

The "*Prodrromus Floræ Novæ Hollandiæ*" (Svo. 1810), might, by a caviller, be said to be mainly a description of dead plants; but its author had observed them living in their native land; and the work, by its combination of anatomical and physiological research with the taxonomic part of botany, made an epoch in the science.

The Government botanical specimens, living and dried, successively brought home from the time of Cook and Banks to that of Flinders and Brown, were disposed, according to the administrative wisdom of the time, the living plants in the gardens at Kew, the dead ones in the herbarium at London. Here was carried out, by the librarians and keepers, the work of naming and describing the new species, the Kew plants duly receiving those assigned to them: the majority of Australian species represented in the Royal Gardens bear the names given them by Robert Brown. Dr. Hooker's definition of this work must also include:—1. "Genera et Species Plantarum Crucifera- rum, necnon Generis Cleome, quæ in Horto Kewensi coluntur;" 1812. 2. "Genera et Species quædam Plantarum Leguminosarum, quæ in Horto Kewensi coluntur;" 1812, 1813. 3. "Genera et Species quædam Plantarum Myrtacearum, quæ in Horto Kewensi coluntur;" 1812. 4. "Genera et Species quædam Plantarum Compositarum, quæ in Horto Kewensi coluntur;" 1812. 5. "Genera et Species Plantarum Orchidearum, quæ in Horto Kewensi coluntur;" 1813. 6. "Genera et species Plantarum e variis Familiis, quæ in Horto Kewensi coluntur;" 1813.

These works, by Robert Brown, performing in London, for the behoof of the Royal Gardens, the labours of the present "dead

plant staff" at Kew, have been, through a truer estimate than Dr. Hooker's, selected by the "Ray Society" for republication in their issue for the year 1867. They were contributed to botany, as metropolitan herbarian work, leaving the officers of the Royal Gardens free for the legitimate physiological labours and applications of their collections of living plants, and were published without any special grant from the Treasury, either for editing or writing.

The importance of basing on fact the question as between the British Museum and Kew, leads me to think I may be permitted to trespass with a few subsequent examples of such works by Brown and his successor. The botanical collections of the Consul-General of Egypt being transferred to the metropolitan herbarium, the keeper contributed, as an "Appendix" to Salt's "*Voyage in Abyssinia*," the "List of New and Rare Plants," collected during that voyage, 1814. The plants of tropical Africa collected in the expedition by Captain Tuckey, R.N., to explore the river Zaire, or Congo, were described in the "Observations, Systematical and Geographical, on the Herbarium collected in the vicinity of the Congo," by Robert Brown, 1818. The entire arctic herbaria brought home by Captain John Ross, R.N., now in the botanical department of the British Museum, were described by the keeper, in his "List of Plants collected on the coasts of Baffin's Bay," &c., 1819. Captain Scoresby having, in like manner, deposited his herbarium in the metropolitan one, it was described by the keeper in his "Catalogue of Plants found in Spitzbergen," as an Appendix No. V, to "Scoresby's Account of the Arctic Regions," 1820. The botanical acquisitions during Parry's famous Arctic Expedition, have their scientific value in the "List of Plants collected in Melville Island in the year 1820, by the Officers of the Voyage of Discovery under the orders of Captain Parry, with characters and descriptions of the new genera and species," by Robert Brown, &c., 1823. The collections made in the explorations of Africa, by Denham and Clapperton, afforded the subjects for Brown's "Observations on the Plants of Central Africa" in the appendix to the narrative of their travels (1826). The herbaria of Captain Stirling's exploration of the Swan River District, Australia, having been deposited in the British Museum, were described in the Keeper's "General View of the Botany of the Vicinity of the Swan River" (1832). This was followed by the publication, in 1849, of the "Botanical Appendix of Captain Sturt's Expedition into Central Australia," by Robert Brown, F.R.S., &c. (1844). During the retention of the "Dried Specimens of Plants in the East India Company's Museum," the Keeper of the Herbarium of the British Museum contributed "Names and Notes on Indian Plants," in the Numerical Lists of such specimens, 1828-1849; also "Notes and Observations on Indian Plants," in the "*Plante Asiaticæ Rariores*," of Walllich. The "*Flora of British India*" was further elucidated by Robert Brown and his then assistant, John Joseph Bennett, Esq., F.R.S. (afterwards his successor in the British Museum), in the "*Plante Javanicæ Rariores*" of "Horsfield," at that time (1838-1852) curator of the Natural History of the Hon. East India Company.

Dr. Horsfield acknowledges his "great obligations to Mr. Brown." "The examination and arrangement of my herbarium, the laborious duties connected with the superintendence of the figures contained in the work, and the time devoted to the description of the subjects, are by no means the only marks of friendship which I have received from that distinguished botanist." "I have the satisfaction to state that J. J. Bennett, Esq., Mr. Brown's assistant in the botanical department of the British Museum, was found willing to prepare for the press such articles as were left unfinished by Mr. Brown, and likewise to co-operate generally in the preparation of the work."

I submit that the number of plants now cultivated at Kew which bear the names assigned to them in the series of works above exemplified, extending over a period of half a century, is not truly defined as "few" or as "being cultivated at the beginning of the century in a private garden of nine acres."\*\*

The successors of Brown are as willing, perhaps as competent, to perform the duties of the National Herbarium in relation to the naming needs of the National Botanical Garden as was their great predecessor.

After the statement that "Kew is an establishment that is annually called upon to name literally thousands of plants from botanic gardens and nurseries in England and similar institutions abroad." Dr. Hooker concludes the paragraph with the remark that, "Large classes of plants are now cultivated that must be named in the houses where they grow; and many more, the tropical especially, could not be sent to a distance to be named, without serious damage in the transit."† Surely these conflicting propositions betray the confusion of mind attendant on an attempt to defend the untenable. Some of the "literally thousands of plants annually" sent from con-

\* "Du reste, s'il ne donnait pas officiellement au Roi des conseils politiques, il n'en était pas moins pour lui un conseiller très-réel et très utile. Il partageait des occupations rurales, il lui faisait connaître les productions intéressantes des pays éloignés, et entretenait ainsi en lui ce goût pour la nature, qui avait déjà valu aux sciences tout d'acquisitions, et qui leur en valut davantage, à mesure que l'exemple du Prince fut imité par les grands. C'est ainsi que, pendant trente ans, l'Angleterre a été en quelque sorte le centre de la Botanique et le marché des plantes et des arbustes nouveaux."—Cuvier, *Eloge de Banks*, p. 82.

tinental and provincial gardens to Kew to be named must be in the condition of those defined as "large classes," incurring "serious damage" in the transmission. It would be desirable, therefore, to shorten the journey as much as possible. Under present railway conditions, they must reach some London terminus *en route* to Kew. Why not receive the needful naming at the National Herbarium in London? The van-carriage to the "London and South-Western station," with probable change of train at the "loop-line," in order to reach the "competing herbarium," would be saved.

Again—Were none of the subjects of the "extensive influx of curious exotics poured into the Royal Gardens"\* (under the direction of the Aitons, in the condition of the tropical ones which, under the direction of the Hookers, "must be named in the houses where they grow?") † Perhaps the authors of the "*Hortus Kewensis*" brought the characteristic parts only of such plants to the metropolitan herbarium. Howsoever that might be, there, in London, the naming of the Kew plants was satisfactorily effected, and the work gratefully and gracefully acknowledged. I would, moreover, ask the attention of an administrator to the fact that the Aitons were thus, and under this division of labour, *directly* responsible to the Crown and the public for the physiological work in relation to the culture and naturalization of living exotics; their responsibility was not

trations for its true progress in every department—experimental, economical, and descriptive. Therefore it is in relation to the true help which a national botanical garden, library, and herbarium can render to botany that I respectfully commend the views and practice of Sir Joseph Banks to the administration of the time being who may take the question of the competing national herbaria into consideration.

No one had a truer, a more sincere regard for the well-being and advancement of his favourite science than Sir Joseph Banks. The formation of this herbarium and library; the choice of Dryander, Solander, Robert Brown, for their custody; his open hospitality to all men of science, the liberal use he made of his treasures during his lifetime, commend the deference of the administrator to Banks's posthumous dispositions. No man could form a truer view of the right places of collections of dead and living plants in their respective services to botany; after the King, no one had taken a warmer personal interest in the formation, development, and applications of the Royal Botanical Gardens, at Kew, than Sir Joseph Banks. His matured conclusions as to the best local conditions of the continued application, after his demise, of these several instruments to the progress of botany are manifested by the bequest of his herbarium and library to the

Gathering Ling (*Fraga bicornis*) in China. (See p. 208.)

shifted to the shoulders of the herbarian botanist, nor their operations controlled or thwarted by him. Each had his appropriate sphere of work.

Mr. Bentham, P.L.S., in a letter admitted into the number of *Nature* for November 11, 1872, is indignant at the suggestion that officially reported failures in physiological operations at Kew Gardens might relate to the proportion of the director's time given to herbarian work. And in reference to the conditions under which the plants growing at Kew were named, before the gardens and their director were encumbered with collections of dried plants, he remarks, that the Banksian herbarium had not become "National" till after the demise of the founder in 1820—a remark akin to that which defines the botanical garden at Kew as a mere "private one" until it became formally, as before it had been virtually, applied to the advancement of science and the public good. The only distinction predicable of the metropolitan herbarium in its application to the nomenclative work at Kew before and after 1820, is one of locality, as between Soho Square and Bloomsbury. The Banksian herbarium and library, like the Royal Gardens, were always "National" in the sense of their free use to botanists for the advancement of botany. In the history of that science the name of Joseph Banks will continue pre-eminent and exemplary to statesmen, in his sagacious adminis-

trations for its true progress in every department—experimental, economical, and descriptive. Therefore it is in relation to the true help which a national botanical garden, library, and herbarium can render to botany that I respectfully commend the views and practice of Sir Joseph Banks to the administration of the time being who may take the question of the competing national herbaria into consideration.

## WORK FOR THE WEEK.

## PRIVATE GARDENS.

**Conservatories.**—Indoor plants have almost invariably started into growth, therefore, such as require a shift must at once receive that attention. Borders in which plants are growing should be lightly forked up, and if the soil is exhausted a dressing of loam, leaf-mould, rotten manure, or good peat may be added according to requirements. Some plants need more water than others, and in such cases neatly-formed basins of soil should be made around them, so as to retain sufficient for their wants without overflowing. This is an excellent time for transferring plants from pots to conservatory borders, and in doing so, disentangle and spread out the roots as much as possible. This may check growth for a time, but eventually, other circumstances being favourable, plants so treated will succeed better than such as are planted with the roots coiled up in a ball. Camellias, Rhododendrons, Acacias, &c., when grown in pots, are more under control than such as are planted out; but the latter are generally the most satisfactory, both as regards growth and bloom. *Clianthus puniceus* if too thick should have its shoots thinned out a little, so as to give sufficient light to the flowers. Passionflowers should be pruned well in, and the soil in which they are growing should be thoroughly saturated with water, so as to induce them to start freely into growth. Cut in the branches of *Habrothammus*. Several of the free-growing *Fuchsias* are well suited for conservatory-roof decoration or that of pillars, especially when planted out in borders. If trained to the rafters from the middle of April until they are completely denuded of side branches in the end of October or November, for the purpose of resting them and admitting light to the other inmates of the house, they form objects of interest, being richly laden during all that time with both flowers and foliage.

**Stoves.**—In these vegetation is in a more forward state than in conservatories, consequently a moist atmosphere and steady but gradually increasing temperature are requisite. *Ixoras*, *Dipladenias*, *Clerodendrons* of the *Balfourii* type, *Stephanotis*, *Bougainvilleas*, &c., will now be growing freely; therefore they should have abundance of tepid water at the root, and their shoots should be trained on string along the rafters, or over trellises. Pot plants, as a rule, will have been shifted, but where they have not, that operation should be performed at once. Sometimes the plants do not require repotting, but in that case any of them that are sickly should be shaken out of the pots they now occupy; the old soil should be removed from their roots, and they should then be replaced in pots of the same or perhaps less size, according to circumstances: overpotting is injurious to most plants. Pitcher-plants should be top-dressed or repotted, and by means of additional heat and moisture, and a little shade, started into growth. *Cissus discolor*, grown in borders or beds, has, in many places, been very beautiful during the winter, and by being pruned now, it will break freely and grow rapidly. *Allamandas* now starting into growth must be encouraged. Plants of *Euphorbia jacquiniiflora* grown in borders against back walls form fine specimens and flower abundantly; the flowering points of such plants, if not already done, should now be cut off, and an early growth encouraged; for the sooner growth is produced and matured the better will the plants flower. *Poinsettias* should be kept quite at rest in an intermediate house, or cool part of the stove, and *Aphelandia aurantiaca* may be treated in the same way. Sow some seeds of *Cyperus alternifolius*, and divide the old plants; both the green kind and the variegated variety make fine subjects for table decoration when in a young state. The fine-leaved *Begonias* may now be shifted and started into growth; they are not quite deciduous, but a long rest in winter greatly invigorates them and improves the succeeding crop of leaves. *Caladiums*, *Gesneras*, *Achimenes*, *Curculigos*, *Gloriosas*, herbaceous *Begonias*, &c., should also all be started into growth, potted as they advance, and be liberally treated.

**Bedding Plants.**—The stock of these should now be increased in every possible way. A brisk bottom heat, drip-proof pits or frames, clean sharp sand, suitable soil, plenty of space and plants to procure cuttings from, are the requisite conditions for this purpose. *Verbenas*, *Heliotropes*, *Ageratum*, *Lobelias*, dwarf *Tropaeolums*, *Pelargoniums*, *Chrysanthemum Sensation* and the green-leaved summer-flowering kinds, *Coleuses*, *Iresines*, *Alternantheras*, *Gazanias*, &c., strike by means of cuttings in a few days, and may be potted singly into thumb pots before their roots are more than an inch long. If these pots are plunged in heat, well shaded and kept moist, they never exhibit a check, but grow apace, and in a few days afford young tops for cuttings, and then side shoots for the same purpose; after that, give them another shift into sixty-sized pots. If pots are scarce, all the strongest plants, after being well hardened off, may be planted out next month in frames, kept close for a few days. *Coleuses*, *Alternantheras*, and *Iresines*, being rather

tender, should be kept in pots until they are planted out. Subtropical plants, such as *Solanums*, *Abutilons*, *Wigandias*, *Ferdinandias*, &c., should be stripped of what cuttings may be on them every week. Maize, Castor-oil plants, *Solanums*, &c., should be raised from seed, and the seedlings should not be allowed to get root-bound, otherwise a stunted growth will be the result; they ought, therefore, to be pricked off as they germinate into small pots, and be shifted from them into larger ones. *Dahlia* roots are now yielding plenty of cuttings, which should be taken off when fit for separation, struck in heat, and treated like other strong-growing half-tender plants. *Canna* roots may be divided, potted singly, and grown in a stove temperature for a short time. Pot some *Gladiolus* roots for early flowering.

**Indoor Fruit Department.**—Pine-apples that have not been already shifted should now be repotted or transplanted into beds. Whether grown in pots or planted out in frames or pits, the heating material should be entirely or partially renewed. If fire heat is used for bottom heat, greater care than would otherwise be necessary must be exercised in watering, as the bottom part of the soil frequently becomes dry when that on the surface is apparently quite moist. Now that the store plants are beginning to push, the atmosphere as well as the soil in which they grow must be kept moist. Ventilate a little during the heat of the day, and cover the frames with mats at night. Fig trees in pots will be swelling their fruits; therefore, some liquid manure given to them two or three times a week will be of great importance to the crop; mulchings of manure answer the same purpose. Those on walls or on front trellises should be started in succession, by closing up the house, syringing twice a day, and stopping the shoots at the third and fourth joints. Pot Vines, if liberally fed, will produce good crops; and, as they are frequently thrown away after bearing, as many bunches may be left on them as they can properly mature and colour. Thin Grapes in general, stop and rub off young shoots, encourage good foliage, and maintain a brisk moist temperature except in late vineries. All old Grapes yet on Vines should now be taken off and preserved. The dampness of the winter has been rather productive of mouldiness amongst those kept in water-bottles. Regulate the growth of Peaches and Nectarines, and disbud and thin the shoots as necessary; thin out, also, all the smallest fruits, and syringe morning and evening. Keep Cherry houses well aired. Introduce successions of Strawberry plants, and place them on top shelves in vineries or Peach houses, or arrange them near the glass in pits or frames, when a little bottom heat given by fermenting material is very beneficial to them. To plants whose fruit is colouring little or no water should be given, as it deteriorates the flavour. Sow the main crop of Melons and Cucumbers, and pot off those already up; such as are large enough may be transplanted permanently. Beds for the reception of the seedlings should be formed completely of fresh soil, for from the plants raised now the greatest amount of fruit is commonly obtained.

## NURSERIES.

**Indoor Department.**—The general spring potting must yet occupy most attention; attend to tropical plants first, the others afterwards. Both foliage and flowering plants, if not previously shortened, should be cut back, and all available shoots so separated should be made into cuttings. The roots of young growing plants must never be allowed to become matted; on the contrary, as soon as shifting is seen to be necessary, it must be done until the plants attain the usual saleable dimensions, when for their final shift good substantial peaty or loamy soil should be employed, and the temperature should be gradually reduced. Roses grafted before Christmas will now have formed shoots a foot or so in length, and some of them may be bearing flower-buds; they should therefore be shifted into 6-inch pots, using a compost of three parts good loam, and one part leaf-mould or rotten manure. These plants should be transferred to an artificially-heated pit, so as to give the younger ones more room in the propagating house. Unfasten the ligatures of grafted Roses, Clematises, Ivies, Daphnes, Conifers, &c., as soon as the grafts are thoroughly united. Continue the grafting of Clematises, using either rooted plants or pieces of the roots; these plants in most instances are readily raised from cuttings, but those of the lanuginosa section seldom root freely; consequently they are almost entirely increased by means of grafting. Repot them when growth has fairly begun. Now is the principal season for grafting Rhododendrons, but success cannot be expected unless the stocks are well rooted and in active growth. Whip or saddle grafting suits them best, and a little clay rubbed over the junction assists the union. Keep the grafted plants in intermediate pits and shade closely. If they are too tall for standing erect they may be laid on their sides. Camellias, Azaleas, and Oranges may yet be grafted under the same conditions as Rhododendrons. Now is the right time to start young plants of these into growth. As they advance prune them back three times during the season, by which means stubby and good

flowering plants will be obtained. Any unshapely old plants of these may now be cut down to the bare stumps, for few plants bear pruning better than these, more especially the Orange. Pot off cuttings of *Euonymus*, *Euryas*, *Conifers*, and stove and greenhouse plants that are sufficiently rooted; any found not to be in that condition should be re-inserted and treated as before. Sow seeds of the finer kinds of *Conifers*, such as *Deodars*, *Cypresses*, *Araucarias*, &c., in frames and pits, and pot singly or prick off in seed-pans or boxes those sown last spring. Two-year-old seedlings may now be transferred from frames or boxes into lines in the open ground in well-sheltered positions.

**Messrs. Veitch's Young Gardeners' Institution.**—All young gardeners with whom I have conversed are delighted with the account which you have given (see page 196) of this institution; and to Messrs. Veitch our hearty thanks are due for having laid the foundation of a system for improving the condition of young gardeners that I trust may be imitated in all parts of the country. The young men now so well cared for at Chelsea will, I feel sure, not forget in after life the comforts of those under them when they come to be head gardeners, and thus the "bottle," with its long train of discomforts, may be exchanged for a clean and healthy residence.—A YOUNG FOREMAN.

## LAW NOTES.

### COUNTY COURT COSTS.

THIS was a question as to the costs to be allowed to attorneys for conducting business in the county courts. It appeared that a Mr. Barnes sold a quantity of Potatoes in the Leicester market to a person named Vesty, and not being able to obtain payment of the balance due to him in respect of these Potatoes, Mr. Barnes instructed his solicitor to commence an action against Vesty to recover the money owing, which was a little over £20. Accordingly, an action was commenced in the Court of Common Pleas, at the suit of Barnes against Vesty, to recover the sum which Barnes claimed. For certain reasons this action did not proceed after the writ was issued and served on Vesty for several months; and in April, 1872, Vesty brought an action in the county court at Leicester against Barnes, to recover a sum of between £9 and £10, the damages which Vesty alleged he had sustained in consequence of Barnes failing to deliver to him Potatoes which Vesty had contracted to purchase of Barnes. Mr. Barnes instructed his solicitor to defend him in this action, and also to proceed with the action against Vesty in the superior court. It was necessary for Mr. Barnes's interest that the action in the superior court should be remitted to the Leicester county court for trial, and that both actions should be tried at the same court. It should be stated too that the disputes between the parties were of that description that a verdict for one or other of them in the first action which was to be tried was likely to determine the verdict in the other action, Barnes claiming a sum of money, the balance of the purchase money for Potatoes supplied to Vesty—Vesty suing Barnes for not delivering those Potatoes at all, a man named Morgan appearing on Vesty's behalf, and stating that Barnes had sent the Potatoes to him (Morgan), and that he, not knowing what to do with them, had sold them as best he could for Barnes. Both actions were ultimately tried at Leicester, and in both Mr. Barnes was successful. All this litigation could not be conducted without expense, and in due course Mr. Barnes's solicitor sent in his bill, which included charges of preparing for trial in the two actions, and contained a fee of £2 1s. 6d., paid to a barrister-at-law, with the brief in the county court action, and certain payments for telegrams, &c., necessarily incurred in the business. An objection was taken on the part of Barnes that, under the provisions of the 19th and 20th Viet., c. 106, sec. 36, his solicitor was only entitled to recover 15s. for all the trouble involved in getting up the county court case for trial, and a payment out of pocket of £1 3s. 6d. for counsel, although it was not disputed that £2 1s. 6d. had been actually paid out of pocket for counsel, besides telegrams, &c. The language of the section thus relied upon to deprive the solicitor of his costs, except the dry allowance of 15s. to the attorney, and £1 3s. 6d. to the counsel, is as follows:—"Where in any action the debt or damage claimed shall not exceed £20, an attorney shall not be entitled to recover from his client any further costs or charges in the conduct of such suit than those mentioned in the 21st section of the Act of the 9th and 10th years of the reign of her present Majesty, chap. 95, unless upon taxation of costs the registrar be satisfied, by writing under the hand of the client, that he has agreed to pay further costs or charges; and in such case the registrar may allow any costs or charges, not exceeding the amount which may have been so agreed to be paid." The bill of costs was originally submitted to Master Dodgson, of the Court of Common Pleas, for taxation, and he referred the county court costs to the registrar of the county court at Leicester, who held himself bound by the above-quoted section of the Act of Parliament, and refused to allow any more costs to Mr. Barnes's solicitor than the 15s. attorney's fee, and £1 3s. 6d. the counsel's fee, as the solicitor had not, in his view of the case, obtained any agreement in writing from Barnes to pay further costs, although the registrar admitted that the charges were perfectly reasonable, if he had power to allow them.

Against this decision of the registrar Mr. Barnes's solicitor appealed. It was contended that the allowance of 15s. for the attorney and £1 3s. 6d. for the counsel only applied to the business actually conducted by the attorney and counsel on appearing in court on the court day, and that for all other charges necessary for properly preparing his client's case for trial the attorney was entitled to recover from his client fair and reasonable remuneration. In support of this view, he relied on the original County Court Act, 9 & 10 Viet. c. 95, s. 91, and the cases *re Keighley*, 19 Law J. Rep. (N.S.) C.P. 166, and *re Toby*, 12 Adolphus and Ellis, 691, which established the principle that an attorney is entitled to recover from his client all reasonable costs in a county court action, both before plaintiff issued and afterwards in getting up the case for trial, besides 15s. for the attorney and £1 3s. 6d. for counsel, for appearing in court on the court day. Against this application it was contended that the two cases above relied upon were overruled by the Act 19 & 20 Viet. c. 108, s. 36, and were no longer law. The Judge decided that the ruling of the registrar was right, and that an attorney, in any action where less than £20 was in dispute, could only recover 15s. for himself, and £1 3s. 6d. for counsel, no matter what trouble he had taken, or payments he had actually made out of pocket, unless he had protected himself by obtaining from his client his agreement, in writing, to pay further costs or charges, pursuant to 19 & 20 Viet. c. 108, s. 36.

**Damaging Trees.**—James Annett, 42, labourer, pleaded guilty to feloniously and maliciously breaking thirty-five Apple trees, fifteen Pear trees, and six Plum trees, growing in a garden, the property of Mr. Wm. Maton, at Penton Grafton, on the 7th February last, and was sentenced to four months' hard labour.

**Stealing Rose Trees.**—Two young Devonshire men were charged the other day with stealing Rose trees from a villa garden at Paignton. One of them was acquitted; but concerning the other it was said the Bench had taken some time to consider their decision in the case. They had no difficulty at all in convicting the defendant of having stolen the Rose trees; the only doubt in the minds of the magistrates was whether they should send him to prison or not; but they were willing to take a more lenient view of the case. They should inflict a penalty of £10, or two months' imprisonment, with hard labour.—Prisoner said he should appeal against the decision. The fine, however, was paid.

## COVENT GARDEN MARKET.

MARCH 14TH.

**Flowers.**—Of these there is a good supply, especially of Tulips, Crocuses, and Hyacinths, all of which are remarkably fine. Cyclamens are plentiful and excellent; Chinese Primulas are on the wane; Cinerarias, Spiraeas, Heaths, Deutzas, and many other plants are supplied in pots. Cut flowers consist chiefly of Camellias, Lily of the Valley, Gardenias, Roses, Orchids of different sorts, and other things now in season.

**Fruit and Vegetables.**—Of fruits there is at present but a moderate supply; Shadlocks and Spanish Melons are beginning to disappear, and Bananas are not so good as they will be by-and-by. Excellent Pine-apples are still imported from St. Michael's. Of last year's Grapes there is still a good supply, consequently prices are lower than usual at this season of the year. New Grapes have also made their appearance; and forced Strawberries are good and plentiful. For good outdoor vegetables there is a brisk demand, and the produce supplied continues to be of excellent quality. Of young Potatoes there is a fair supply from Malta and the West Indies; also frame-grown ones from the Channel Islands. Salading and forced vegetables are of good quality, and the supply about equal to the demand.

**Prices of Fruits.**—Apples, per half sieve, 3s. to 5s.; Chestnuts, bushel, 12s. to 20s.; Cobs, per lb., 2s. 6d.; Grapes, hothouse, per lb., 6s. to 12s.; Lemons, per 100, 6s. to 10s.; Oranges, per 100, 1s. to 10s.; Pears, kitchen, per doz., 1s. to 3s.; dessert, per doz., 8s. to 12s.; Pine-Apples, per lb., 6s. to 10s.; Strawberries, per oz., 1s. to 2s.; Walnuts, per bushel, 15s. to 30s.; ditto, per 100, 2s. to 2s. 6d.

**Prices of Vegetables.**—Artichokes, per doz., 3s. to 6s.; Asparagus, per 100, 5s. to 10s.; Beans, Kidney, per 100, 2s. to 3s.; Beet, Red, per doz., 1s. to 3s.; Broccoli, per bundle, 9d. to 1s. 6d.; Cabbage, per doz., 1s. to 1s. 6d.; Carrots, per bunch, 6d.; Cauliflower, per doz., 2s. to 4s.; Celery, per bundle, 1 s. 6d. to 2s.; Coleworts, per doz. bunches, 2s. 6d. to 4s.; Cucumbers, each, 1s. 6d. to 3s.; Endive, per doz., 2s.; Fennel, per bunch, 3d.; Garlic, per lb., 6d.; Herbs, per bunch, 3d.; Horseradish, per bundle, 3s. to 4s.; Leeks, per bunch, 2d.; Lettuces, per doz., 1s. to 2s.; Mushrooms, per pottle, 2s.; Mustard and Cress, per punnet, 2d.; Onions, per bushel, 3s. to 6s.; pickling, per quart, 6d.; Parsley, per doz. bunches, 1s.; Parsnips, per doz., 9d. to 1s.; Peas, per quart, 6s. to 10s.; Potatoes, per bushel, 1s. to 7s.; Radishes, per doz. bunches, 1s.; Rhubarb, per bundle, 8d. to 1s. 6d.; Salsafy, do., 1s.; Savoy, per doz., 2s. to 3s.; Scorzoneria, per bundle, 1s.; Seakale, per basket, 1s. to 2s.; Shallots, per lb., 3d.; Spauch, per bushel, 3s. 6d. to 5s.; Turnips, per bunch, 3d. to 6d.

**The Welsh Leek.**—Everybody knows that "Taffy" wears a leek upon St. David's Day, but it is doubtful if any one knows the origin of the custom. One writer thinks it originated in Druidic times, and that the plant was a symbol of Ceadven, the British Ceres. Others maintain that it was the sign under which the Welsh gained a victory over the Saxons, St. David having advised them to assume the badge. Certain it is that the Rose, Shamrock, and Thistle are not more honoured in the countries which have adopted them as emblems than is this odorous potherb in Wales.

**Gutta Percha.**—The declared value of gutta percha imported last year was £100,681, and in the previous year £196,942.

## THE GARDEN.

"This is an art  
Which does mend nature: change it rather: but  
THE ART ITSELF IS NATURE."—*Shakespeare.*

### THE LACE-WING OR GOLDEN-EYE.

(*CHRYSOPA FERLA.*)

LET us hasten to premonish the non-entomological reader that the lace-wing or golden-eye (*Chrysopa perla*), figured below, comes within the limits of our subject, not as an enemy but as a friend—not as a garden destroyer, but as a destroyer of garden destroyers. It is the great destroyer of green-fly; hence all gardeners will look upon it with respect. Its aspect (that is, the aspect of the perfect insect) is by no means suggestive of destruction; a more delicate, beautiful, and ethereal creature cannot well be imagined. The species are pale greenish, or yellowish, or almost white. The wings are like a film of lace, the body, "as thin of substance as the air," and its eyes large, prominent, and like polished golden globes glittering in the sun.

Although called a fly, it is not truly what is ordinarily meant by that word. It is not a two-winged fly like the house-fly, but belongs to the same order as the dragon-flies, and forms

The Lace-wing, or Golden-eye insect.

one of the genera constituting the family Hemerobiidae. There are about a dozen of species of *Chrysopa* found in Britain, of which the commonest is the one of which we now speak. They are common about hedges, gardens, fields, plantations, &c.; in fact, wherever they prey, the green-fly is to be found. They fly principally at night, and are sluggish and easily caught by day. Although so lovely, they are, in one respect, like a whitened sepulchre. They have a bad smell. They are common in June, July, and August, in which months the eggs are deposited in a very remarkable fashion. The reader will see in the woodcut, at No. 2, something like an aigret, a few hairs, surmounted each by a knob standing out all round. These knobs are the eggs, and they stand upon a fine elastic, flexible hair-like stem. It is not difficult to conjecture how they are thus laid. There must be a glutinous liquid near the ovipositor which envelops the egg, and does not immediately part from it when the female places it on the leaf or object on which she is laying. As she withdraws her abdomen from the spot the egg does not readily quit it, but the gluey matter is drawn out like a thread of sealing-wax, and when it parts the egg is left standing on the top of it. The length of this hair of glue varies. It is sometimes as long as an inch; at other times shorter. These eggs are thus very curious looking objects, and we well remember how puzzled we were when we saw them for the first time. It was on a Cherry where several were standing, and like others before us, we were at first disposed to take them for some sort of vegetable production, a fungus or the capsule or seed-vessel of some Moss. It is unnecessary to say that this contrivance is a very effectual

protection from enemies, the elasticity and tenuity of the hair or stalk giving no hold to any creature that might attempt to lay hold of it. The eggs are often laid in clusters, as here represented, but as frequently one by one at little distances from each other.

It is the larvæ that are the real enemies of the green-fly—the perfect insect apparently eating little or nothing. But the larvæ make up for it. They are called by the French "lions des pucerons," or green-fly lions. They vary considerably in colour, being brown or whitish with orange spots, and having sixteen fleshy tubercles down the sides, but they are difficult to detect unless when engaged in the actual occupation of seizing and devouring their prey. They cover themselves with a coat of many colours, composed of portions of the green and delicate lichens which cover old trees or palings, or of the skins of the green-fly that they have sucked dry, so that unless when they are in motion it is not possible either for the prying eye of the entomologist, or the still quicker eye of the titmouse and other small birds to detect them; and thus disguised they lie in wait with patience for their prey. When amongst them, however, their sluggishness vanishes, they seize them with their long and powerful jaws, and will devour the largest of them in half a minute, leaving nothing but the skin. They are exceedingly voracious, and will clear a whole leaf from green-fly in an incredibly short time. After feeding in this way for about a fortnight, they go into the chrysalis state, first spinning a small whitish cocoon, which they attach to the leaves of plants, and about which the pieces of lichen and skins of flies that formed the covering for the larvæ usually stick; but the remarkable thing is, that this silken cocoon is spun, not from the mouth of the insect, but from its tail, as is done by the spider. It would seem that it must be spun from the same reservoir of glutinous matter which supplies the hairs on which the eggs stand, and seems opposed to the view entertained by Curtis and other entomologists that this reservoir is in the ovaries. The cocoons are very small—so small that it is a matter of surprise how the long wings of the perfect insect could ever have been folded up in them—often not bigger than a Barleycorn or small Pea. In this they change to the pupa, and in the summer time they come out in the perfect state in about three weeks; but those that pass into the pupa in autumn, remain in it until spring. A. M.

**Crocus Enemies.**—Every year at this season my Crocuses are cut off obliquely, just below the corolla, and the colourless tube which descends towards the root is left untouched. On inquiry, I find that my neighbour's Crocuses are served in the same manner, and that this calamity extends as far as Croydon, where the blossoms of hundreds of the common yellow Crocus are thus annually cut off. I do not follow the customary plan of asking for a remedy; that plan I always regard as putting the cart before the horse; but I think I may very properly ask some of your readers who are acute observers what is the mischief-maker, and when I have obtained this information, I will deal with him to the best of my ability.—EDWARD NEWMAN, *York Grove, Peckham.*

The correspondent of the *Daily News* thus describes his introduction to the Orange-groves of Spain:—"It was still the grey morning twilight, when, having passed through the grim hills above La Lucina, we rattled into the long tunnel that begins soon after that station is passed. When we emerged from the tunnel the sun had risen, and his beams lit up a landscape of amazing beauty. There were no longer barren hills and sandy flats. The broad undulating plain was bright with foliage. On the hill sides were low-roofed, white cottages, shimmering out from the little groves of Orange trees and Cacti that surrounded them. A village, with a tall minaret springing from its centre, nestled compactly under a steep hill, crowned with a castle that belonged to the Templars. The terrain was like a garden, the sprays of flowering shrubs grazing the sides of the railway carriages. From a Malberry grove miles long we shot suddenly into the gardens of the Hesperides, the Orange forests of the Huerta of Alcira. On every side were laden Orange trees. Beautiful was the sheen of the dark green foliage, but yet more beautiful was the ripe fruit that gleamed in rich golden splendour from under the leaves. Not one or two globes, dangling shamefacedly on the branch of a stumpy plant, as Orange trees are seen in England, but countless clusters of yellow fruit hanging from every spray of trees corpulent in trunk, and wide-spreading in bough."

## NOTES OF THE WEEK.

— THE Council of the Royal Horticultural Society have framed bye-laws which, if confirmed at the forthcoming adjourned general meeting on the 26th inst., will enable the present Council to resign in a body, which is what they are anxious to do, in consequence of the adverse vote of the general meeting of the 18th ult.; and the Horticultural Defence Committee recommend the Fellows to adopt the new bye-laws, in order that the existing Council may resign, and that a new one may be formed.

— A PRUSSIAN horticulturist has made some interesting observations which tend to show the usefulness of certain plants as weather guides. Thus he finds that the different varieties of Clover contract their leaves on the approach of rain. When the leaves of Chickweed unfold, and its flowers remain erect till midday, fair weather is at hand; but the closing of the flowers of the Wood Anemone indicates that rain is imminent.

— OF *Picea nobilis*, perhaps the finest specimen in Britain is that growing in the grounds at Coul House, Ross-shire, the seat of Sir Robert Mackenzie, Bart. This tree is about forty years old; it is 60 feet in height, and, judging from a photograph of it with which we have been furnished, it has a grand and majestic appearance, standing out, as it does, in bold relief from the commoner objects with which it is surrounded. This fine Conifer attains great perfection in the north of Scotland, especially if planted as this is in a tolerably favourable situation.

— MESSRS. WOLFE, of the Steam Pencil Works, 55, Great Queen Street, Lincoln's Inn Fields, have sent us a sample of their indelible garden pencils, of the durability of the markings of which, when subjected to atmospheric influences, we have heard good accounts. They are cheap, furnished with a brass hose to protect the point, and are equally as well suited for the ordinary purposes for which black-lead pencils are used as for writing on garden labels.

— IN the last two months the declared value of Potatoes imported was £544,639, and in the same period of 1872 only £35,963. Last month the value was £262,336, against £19,976 in the month of February, 1872.

— THE Pine woods of Scandinavia are likely to be turned into "broadsheets." A Dr. Silchester has been for some time in Sweden making experiments on the natural sawdust, and has succeeded in producing a pulp, of which excellent paper can be made.

— AN exhibition of spring flowering plants, chiefly Hyacinths, belonging to Messrs. Downie, Laird, and Laing, will take place in the central transept of the Crystal Palace, Sydenham, to-day, and will continue therein for the next fortnight, viz., until the 5th of April. Hyacinths and their culture having charms for everybody, this exhibition cannot fail to be attractive.

— THE Committee of the Stamford Horticultural Society conceived the idea, last season, of holding a children's May-day or garland show, an undertaking which was entered into both by the children and by the promoters with great spirit, something like eighty entries having been made. The prizes ranged from 10s. downwards, and the judging gave great satisfaction. Through the kindness of Messrs. Jeffery & Luke, the exhibition took place in an enclosed field, in which a tent was erected, and in which about 300 of the youngsters were regaled with tea and cake. Exhibitions such as this are surely worthy of encouragement.

— ST. PATRICK'S DAY has brought the usual crop of speculators as to what the true Shamrock is. It is not *Trifolium repens*, or any of the *Trifoliums*. Irish pictures and illuminations prove the ancient emblematic Shamrock to have been a plant of quite another order—viz., the *Oxalis acetosella*, or Wood Sorrel. This probably grew in prodigious quantities before the extensive woods of Ireland were cut down. The Shamrock of old was said to have been used as food; but one can hardly imagine the possibility of human beings feasting upon *Trifolium*; but the Wood Sorrel is a most refreshing esculent during hot summer days. The *Trifolium* (*T. minus*, *T. repens*) and *Medicago lupulina*, being in good leaf at this time of year, and stronger to resist the wear and tear of the button-hole or hot hand than the *Oxalis*, have doubtless for these reasons become the recognised Shamrocks of modern days.

— WE have received from Mr. Lee, of Clevedon, a few flowers of his new Violet, "Victoria Regina," a kind well worth attention, on account of its size and scent, which is very powerful, and which is retained long after the flowers have been gathered. Although a seedling from the Czar, the leaves are like those of *Devoniensis*, with which it is, no doubt, crossed, as beds of the two sorts grow side by side. Large and fine as *Victoria Regina* is, Mr. Lee is of opinion that it may possibly be the forerunner of a new race of Violets; for out of about thirty seedlings from it there are no two alike. They include also several shades of colour, some having conspicuous white eyes, and being tolerably round in shape. We may therefore eventually hope

to get sweet Violets with forms little inferior to those of *Heartsease*. The blooms are borne well up above the foliage, a point of considerable importance in regard to Violets, the flowers of which are so much wanted in a cut state for indoor decoration.

— THE ornamental waters of the Bois de Boulogne are being utilised for salmon breeding.

— THE managers of the Vienna Fruit Market have decided to hold an International Seed Fair in August, during the Exhibition, on the model of that held at Leipzig.

— THE present year's schedule of the grand Yorkshire gala is before us. The floral and horticultural fête is to take place on June 18 to 20, under the presidency of the Mayor of York (Mr. Alderman Steward), who is also chairman of the committee. We note among the prizes offered one of £25, for a group of 12 stove and greenhouse plants in bloom, and 8 fine foliaged or variegated plants; and Mr. Williams, of Holloway, adds to this a silver cup, value £10, in commemoration of the chairman being appointed Mayor of York. In a class for 6 new and rare plants in or out of bloom, there is a proviso that such of them as are not in flower at the time of the exhibition, and have previously flowered, are to be accompanied by a coloured drawing.

— THE mode in which the fertilisation of Grasses, and especially of Cereals, is effected—a question of no small importance from an agricultural point of view—has recently been the subject of a series of observations by Delpino in Italy, and Hildebrand in Germany; and the latter has published the result of his investigations in the "Monatsberichte" of the Berlin Academy. Both these acute observers are at issue with previous writers, who maintained that the flowers of Cereals, and especially of Wheat, were self-fertilised in the unopened flowers, and consequently that the process could not be influenced by the wind. Hildebrand asserts, on the other hand, that impregnation takes place while the flower is open, and while the stigma is in a condition for the access of foreign pollen, that is, from other flowers. The opening of the flower of Wheat, however, is completed in such a very short space of time that in a Wheat-field there is probably never more than one in 100 of the flowers open at the same time. The contrivances by which in this case, as well as in other Grasses, cross-fertilisation is at least rendered possible, are described in detail in the paper. In Barley, on the other hand, the majority of the flowers never open, and self-fertilisation is the only condition possible. Delpino states, however, that there are in an ear of Barley a very small number of flowers, differently constructed from the rest, in which cross-fertilisation is possible. In the Oat the process is stated to vary according to the weather; in fine warm weather the flowers open freely, and cross-fertilisation is favoured; in cold wet weather they remain closed, and self-fertilisation is inevitable. In Rye, fertilisation from the pollen of other flowers is provided for. The agent in the dissemination of the pollen is scarcely ever insects, almost invariably the wind, to which end both stigma and pollen-grains are specially adapted.—*Nature*.

## THE WILLOWS ON HAMPSTEAD HEATH.

TO THE EDITOR OF THE "TIMES."

SIR,—“You English have no taste,” so said a foreigner to a countryman of ours as they gazed upon our branchless trunks this morning. The remark was made with special reference to the Board of Works, and if any doubt the justice of it, let them come and see us shorn by the monsters of Heath rule of all our beauty. Did they commit the act to provide themselves with fuel during the remainder of the coal famine? Or did they intend it to be an act of kindness, seeing we had just become tall enough to behold the hideous spectacle of our neighbours—the Oaks, Elms, and Firs, at the other side of the road? Poor fellows, they offer a painful sight—their ankles cased in armor and their naked toes left to be trodden on! There was a time when they were regarded as beautiful parts of a beautiful scene—admired by Turner, Constable, and Callcott, each and all of whom delighted to perpetuate them on canvas. Now they appear but little better than the trees of a German box of toys fixed upon stands to secure an upright position. Really, Sir, it is too bad; and we feel the more indignant when we remember the ratepayers are taxed to enable the Board of Works to convert beauty into deformity.

We are, Sir, your obedient servants,

March 14.

THE WILLOWS ON HAMPSTEAD HEATH.

**The Small Birds Protection Act.**—This has now come into operation, and hereafter any one lurking behind the garden fence with a stuffed chaffinch, a call-pipe, and a clap-net, may be at once taken before a magistrate and fined 5s., with an additional sum for each miserable bird captive in his possession.

## THE INDOOR GARDEN.

### ECHINOPSIS VALIDA.

THIS is one of the finest and largest of the genus to which it belongs; its flowers, which are pale rose, are produced in great profusion, so much so that last season on one plant I had two crops of them, each numbering from twenty to thirty blossoms, and even now it is well furnished with flower buds. It grows from 6 to 8 feet in height and 2 feet in circumference, and it begins to flower when only 6 inches high. The spines are nearly black, from 1 to 1½ inch long, and exceedingly strong. Its native habitat is not at present known; but it has been in collections for some time. Like all

*Echinopsis valida.*

the species of this genus, it is a free grower, but throws out no offsets. From what I have seen of it, I should say that it wants but very little heat. J. CROUCHER.

### FORCING FLOWERS.

(MAY OR HAWTHORN).

THIS is one of the most delightful occupations belonging to horticulture. Roses in January, Hawthorn blossoms, the very breath of spring in February and March, what can be more charming? It is not only that the flowers are so sweet, tender, and beautiful, but the associations that cluster around them, like the hum of bees, call forth pleasurable recollections. The flowers of forced May are fresher, brighter, larger, and the leaves likewise, than those on plants that are allowed to come into bloom later in the season. Leaves in out-of-door May are somewhat overlooked. Not one in a thousand possibly when admiring thorns smothered in bloom has ever noted the marvellous beauty of form and the intense greenness of their foliage. In forced May, however, the exquisite beauty of the leaves is brought out in bold relief. The forcing enlarges them, and their shape and colour are distinct from those of most of the plants with which they are associated. Paul's scarlet Thorn, too, one of the best for forcing, has finer leaves than most of the other varieties. Bunches of the bloom of this, cushioned in its own foliage, set round white Camellias in a bouquet in February or March are rapturously beautiful, as are also small vases, baskets, &c., dressed with the flowers and leaves of this May.

Thorns for forcing should be potted early in November, and if grown in pots for one year, the pots should be plunged to the rims in a warm, sunny piece of ground. The pots will thus become full of roots, and the cheek which these will

receive from their circumscribed area will retard growth, hasten the maturation of the wood, and thus fully furnish it with blossom buds before the end of the growing season. Plants thus prepared may be put into heat by the beginning of October, and be made to adorn the Christmas-tide festival with a novel and most appropriate type of new-born beauty. If forced the same season in which they are potted, there will be fewer flowers, and the process should be much slower. Plants properly prepared for flowering in February, March, or April improve year by year, and get into the habit of flowering early. With top-dressing, summer-plunging, and mulching, they will also bloom, for many years in succession, in the same pots, say, 12-inch ones. In fact, nothing can be easier managed than the forcing of May in pots. It will grow in any soil, thrive under almost any treatment—unless, indeed, the early plants are thrust out in the cold as soon as their flowers fade, to have their tender leaves blackened by April or May frosts; that will delay a year's blossom, perhaps cripple the plants for life. As to sorts, all are beautiful. I like to have some of the common single white Hawthorn, also the single pink or red; and, of course, all the varieties of the double pink, white, red, and scarlet, force well, the single white being, perhaps, the most impatient of any excess of heat. With respect to form, I am fond of small standards or pyramids. They are more convenient and perhaps more artistic than those of other shapes; they harmonise, too, better perhaps with other pot plants, and yield a maximum of flowers in a less area than plants of other forms would do. Any shape, however, will do, and any size, though I find pyramids from 5 to 6 feet in height handy sizes. A temperature of from 45° to 55°, with frequent syringings, suits May of all kinds well. An early Vinery or Peach house "at work" is just the place for them until they come into blossom. Then, oh! for the eye of a painter, and the combined taste of all our best decorators to dispose of May plants, wreathed with beauty's choicest garlands, in the best places in rooms or conservatories for the richest effects. All of us, doubtless, often fail in these finishing touches of art. We have, however, this consolation, that May plants look well anywhere, anyhow, and that often by haphazard disposal of them we reach a grace and beauty of setting beyond what could be acquired by studied art.

When the flowers fade—which they are long in doing—and the tender green leaves are safe, plunge the plants for the summer, as I have said, in the eye of the sun, and see that they never flag from want of water, and that no insects feast on their leaves; and next autumn you will find them fuller of life and thicker set with flowers than ever, and so on year after year. D. T. FISH.

### EUPHORBIA JACQUINLEFLORA.

THIS useful winter-flowering plant is seldom seen now in such good condition as it used to be some thirty years ago. To see plants of it then from 4 to 6 feet in height, with from twelve to twenty leading branches, each starting from the base, and a wreath of glowing orange-scarlet flowers, was by no means an unusual sight; now from six to ten spindling plants crammed into a 6-inch pot, each from 18 inches to 2 feet high, are the acme of cultivation. Why this should be I cannot tell, for plants in general are as well grown now as then. For winter decoration this plant is second to none. Its flowers are exquisite in form and colour, and they are persistent. The leaves are lance-like, of delicate (I might almost say transparent) green. For wreaths for the hair nothing can surpass the blooms of this plant, though the Covent Garden bouquetists are not insensible to their value in the art and mystery of their fabrications.

This Euphorbia is a stove-plant—that is, in the winter or blooming season it requires something warmer than a greenhouse temperature; and, indeed, to grow it properly, the atmospheric heat should range from 60 to 75, the former being that of the night, the latter that of the day with sunshine. It is readily propagated by means of cuttings of the ripened wood, which may be put in as soon as the plant has done blooming, say in February or March. The cuttings should be from 2 to 4 inches long, according to the strength of the wood, and the more ripened the wood is the less will be the chance of the cuttings damping off. As a check upon

damping, it will be best to allow the cuttings to dry for two or three hours before they are put in, because when fresh they exude a thick milky juice which, if allowed to accumulate around the base of the cutting, causes it sometimes to damp off. The cuttings being prepared, take some 4-inch pots and, draining them thoroughly, fill them to the brim with a compost of peat and turfy loam in equal quantities, from which the fine particles have been sifted, and to which may be added a fourth of pea-sized charcoal or potsherds, and the same quantity of gritty sand. Mix these intimately together, fill the pots quite solid, and then put in the cuttings, leaving them for a few days without water. The cutting pots should be plunged in a bottom heat of 80°, or nearly so, and in six weeks they will be well rooted and fit to pot off. Those who are desirous of having large specimens quickly, and who do not wish to exhibit them, may elect to grow three or four plants in each pot, while others may not exceed the legitimate number of one plant. The soil used should be two parts turfy, sandy loam, with the fine soil taken out of it, one part turfy peat, and one part flaky leaf-mould, to which may be added sand and charcoal; and, as the plants get larger, a dash of bone-dust, say a handful or half a pint, to each peck of the preceding compost may be added, taking care to thoroughly incorporate it. After the plants are potted off, place them in a close, moist atmosphere until they are established in the fresh compost, and then inure them to the free air of the house, always remembering that it must be a hothouse with a brisk moist temperature. So managed, if the cuttings were strong, the plants will start away with vigour, and produce three breaks each, or perhaps more. Presuming that you have strong plants established in 3-inch pots, let them grow on until the shoots are from 6 to 9 inches long; let the plants dry for a day or two, and then cut each shoot to within four, or, at the most, six buds of the base. From each of these side branches three or more shoots should be produced, and these, nicely trained out, will give a foundation, which, in the second season, should form a fine specimen. It will not be advisable to stop the plant a second time, but the shoots may be allowed to grow to their full length, which, according to the strength of the plant, may be 2 or 3 feet. Of course the plant will require to be shifted into a 6 or 8-inch pot, using the compost already described. For perfect growth a brisk, moist heat must be maintained, and after the pots are full of roots, weak liquid manure may be given once or twice a week with advantage. This will bring the plants to the end of the first season, and as soon as they have done blooming lessen the supply of water so as to promote the ripening of the wood; but do not, as some do, allow the roots to become quite dry; nor put the plants in a low temperature, which is an equally bad practice.

In the second season you will have plants which, with each branch of the previous year cut back to within three or four eyes of the base, will give you a forest of young shoots. The cutting down should take place while the soil is comparatively dry; and to equalise the flow of the sap, so as to cause the buds to break regularly, it is not a bad plan to lay the pot upon its side, turning it twice or thrice a week. In that way the shoots will come away with more uniform strength, and hence will form a better plant. Give water cautiously at the root, but you may syringe the plant almost daily with advantage. When the young shoots are an inch or so long is the right time to re-pot the plant. In doing this turn it carefully out, and without injuring the roots remove as much of the old soil as possible, and then re-pot into a pot a size or two smaller. After this the plant should be plunged in a bottom heat of 80°, and be exposed to a moist growing temperature of from 70° to 80°. Perhaps it may require a second and third shift during the season, but, as a rule, over-potting is worse than under-potting, and hence an 11 or 12-inch pot should be quite large enough for the second season's growth. Whether you stop a second time or not must depend upon the kind of plant you want. If a tall, strong plant be desired, then select a dozen or score of the strongest shoots and allow them to grow to their full length; but if you want a shorter, bushy plant, then, when the first shoots are a foot long, cut each back to four or six eyes, and treat them as already directed. To secure an equal growth at all stages after stopping, it may be necessary to depress the strong shoots by tying or pegging

them down, so as to give the weaker ones a fair chance to start properly; in that manner you may get them all up with tolerably equal strength, so that each will be a wreath of bloom nearly the whole length. To prolong the blooming season, the most suitable temperature will be from 55° to 70°, and in that plants will bloom from November until March.

Those who require this *Euphorbia* in quantity for cutting, will find it advantageous to plant a few plants out, and either train them to a pillar or to a wall where the necessary temperature can be maintained. Thus managed, with the young wood annually spurred close in, and the plant liberally treated as to soil, manure, and temperature, the flowers may, after the plants become established, be cut in quantity, and for bouquet and vase work nothing can be more beautiful. The chief enemies of the plant are thrips, red spider, and mealy bug, all of which must be kept in check and destroyed by the usual remedies.—A.

#### CANARINA CAMPANULA.

This fine old-fashioned plant, which displays its beauty throughout the whole of the winter months, is one which, unfortunately, is too seldom seen in our plant-houses of the present day. It is a native of the Canary Islands, and even upwards of two centuries ago it was held in much esteem by cultivators. It has a tuberous root; the stems are herbaceous, the leaves opposite, and sometimes, though rarely, verticillate; their upper surface is shining dark green, their under side being of a paler hue. The flowers are large, campanulate, and pendulous; orange-red in colour, prettily veined, and very beautiful. I have a plant of it between 2 and 3 feet high, just beginning to open its blooms, which it will continue to do up to March or April. The management which this plant requires is extremely simple; after it has flowered the stems die down, and whilst they are decaying, water must be withheld by degrees, until very little indeed need be given, but I do not keep it quite dry at any time. About the beginning of August it should be repotted in a well-drained pot, using for soil good sandy loam and peat, to which may be added with great advantage a little charcoal and broken lime rubbish. After potting place it in a little heat, from which it should, however, be removed when about a foot high; transfer it then to the greenhouse, to the temperature of which it should be gradually inured, and place it in a dry sunny spot if possible. When the dull days of autumn come on, care must be taken that it does not suffer from damp, for when that happens, the young and growing shoots which produce the flowers become rotten; a little attention will, however, prevent this mishap, and it will then be found to be one of the best of winter blooming plants. G.

*Mantisia saltatoria*.—This singular Gingerwort was introduced to this country in 1808, and flowered about two years afterwards, for the first time in Europe. I well remember with what delight I beheld its flowers unfold in the spring of 1847, which was the first time I had seen it. This plant is of a dwarf stature, seldom exceeding a foot in height. The roots are thick and fleshy, and from them spring the young plants, which bear broad, lanceolate leaves, that taper to a long, slender point, with sheathing bases, both sides being pale green. The flower-spike, which is branching, is thrown up separately from the leaves, and the base of each division of the scape is furnished with a large purplish, mauve-coloured bract. The flowers themselves are yellow and purplish-mauve, and their peculiar structure has led to their being called "Mantis Flowers" and "Dancing Girls." Their resemblance to the insect Mantis in shape is sufficiently apparent; but I confess that it requires a considerable stretch of the imagination to discover in them any resemblance to "Dancing Girls." The filament and anther, with its wing-like margins, are, however, said to represent the head and neck of a girl, the long inner segments of the corolla the arms, and the labellum or lip the dress; but be that as it may, the flowers are both interesting and showy. As regards cultivation little difficulty need be experienced. It should be potted in equal parts of rich loam and peat, with the addition of a little sand to keep the mixture open and porous; the pots should be well drained, for although the plant delights in an abundant supply of water during summer, it cannot be subjected to immersion in stagnant water with impunity; the shoots die down in winter, when water should be withheld, but not entirely, that being the rock upon which so many founder in the cultivation of this plant. Keep it slightly moist during winter, and when it begins to throw up its shoots and flowers, return to the summer treatment and all will be well, whilst at no time will it require much pot room. It is a native of the East Indies, and enjoys the temperature of an ordinary stove.—R.

PHAJUS GRANDIFOLIUS.

THIS is an old inhabitant of our gardens, having been introduced from China in 1772. It is a terrestrial Orchid of the easiest possible culture, and flowers most profusely about this time of the year. When well grown, it soon develops itself, and forms fine specimens, with from twenty to thirty spikes of effective white, brown, and purple flowers. It is a gross feeder, and does well in a compost of fibrous loam, well decomposed hot-bed manure or leaf-mould, and coarse sand. Drain the pot effectually, and then give an abundant supply of water at the roots when the plants are making their growth. Like many more terrestrial Orchids, it is found growing in its native country by the margins of streams. A little weak liquid manure may be given with advantage when it is in full growth.

Phajus grandifolius.

and this also greatly assists such plants of it as are pot-bound. Good specimens are very useful at this season for conservatory decoration. F. W. B.

**Phalænopsis Luddemanniana.**—This handsome Orchid, which has now been for some time in cultivation, is finely figured in a late number of the *Revue Horticole*. It is a native of the Philippine Islands, where this species abounds, and has been named in honour of M. Luddemann, a distinguished Parisian Orchid grower. The pseudobulbs in this species are merely rudimentary, and bear one or two thick leaves of a fine glistening green colour. The flowers are numerous and form a handsome and somewhat compact spike. They have five oval pointed divisions, which are nearly of the same size and shape, of a rosy violet at the base, and bearing, from the base to the apex, broad transverse bands of a vinous red or maroon colour, the whole lustrous as if varnished. The lip is also of a rosy violet colour. A variety (*P. l. ochracea*) differs from the type in having yellowish or pale rosy flowers, in which the transverse bands are of an ochry or chestnut colour. *P. Luddemanniana* is grown in baskets suspended in a moist stove. If they are hung so that the roots, which are all aerial, may reach some soil or decomposed wood, they soon begin to swell, assume large proportions, and communicate a great increase of vigour to the plant. It is multiplied by means of the shoots, which are produced freely.

**Cinerarias with "Blind" Trusses.**—Can you tell me why my Cinerarias (which appear very healthy and dwarf in growth), produce "blind" trusses? They are in 6-inch pots, and have never been attacked by green-fly or anything else. They are not, however, all "blind." Some are showing beautiful blooms, mixed with the "blind" trusses. They have been watered twice a week with weak manure, made from fowl's dung, and all have had the same treatment.—HIGHFIELD. [Over-feeding or undue excitement in the way of temperature is probably, in your case, the cause of failure.]

THE FLOWER GARDEN.

IVIES.

FOR many years the Ivy seems to have been neglected as a decorative plant, partly because the normal form is such a common country object that few woodland walks can be traversed in which some fine specimen may not be met with. But, although I do not despise the common forms found everywhere in a wild state, I wish to draw the attention of the readers of *THE GARDEN* more especially towards the many pretty varieties which may now be purchased for a trifling sum from almost any nurseryman. Passing through a small village on the banks of the Mersey (Juce, Che-hire) recently, I was fortunate enough to observe the finest specimen of *Hedera argentea minor* (covering the walls of an old-fashioned farmhouse) that I have ever seen. It was not a small, dwarfish, half-dying and withered example; but had a main stem four inches in diameter, and branches and leaves spreading over a surface of not less than twenty square feet. Moreover, it was a genuine variety; and although I did not examine every leaf minutely, yet I do not think I exaggerate when I say I believe every leaf was uniform in colouring. I lay great stress upon this uniformity in colouring, as constituting a good and well-marked variety. On this account many so-called varieties are worthless, and cause much disappointment to the amateur. A friend of mine some time since wished to secure a good selection of the golden and silver-variegated Ivies. He had carefully trained a few specimens of the Irish Ivy (*Hedera canariensis*) in various positions about his house and garden, then he thought he would purchase a few varieties to contrast with these. After searching over many of the noted catalogues, he at length decided both upon the names and quantity. At first they were but small pot-plants—therefore it could not be expected that they would show many characteristic marks; but judge of his disappointment, after three or four years' cultivation: one specimen, rejoicing in as many names as a Spanish grandee—viz., *Hedera canariensis argentea major palmata-marginata*—merely had some of the leaves slightly marked with whitish spots, somewhat as if white paint had been sprinkled over them, whilst most of the leaves were quite plain, or just tinged with golden blotches. The whole of his expensive specimens, excepting two or three, turned out to be the genuine *Hedera Helix* of English botany.

It is only when growing in a perfectly natural state that the Ivy or its varieties can be really called handsome; when it is clipped and trimmed Dutch fashion, it loses all its effect. I once saw what may with truth be called a famous Ivy. A large Elm tree had been struck by lightning in an extensive park, which necessitated its owner to saw off the head, or upper branches, about 15 feet above the roots. Soon afterwards a small plant of the Ivy began slowly to creep up the gnarled old trunk, until, after the lapse of a few years, it had clothed it with a rich drapery, and hung from the summit in rich festoons. On one side, where a huge wart-like excrescence bulged out, a fine tuft of the common Polypody (*Polypodium vulgare*) had found a congenial home; and thus, betwixt the two evergreens, an unsightly trunk was transformed into a rich embellishment. The proprietor of the park thought more, perhaps, of this naturally-formed adornment than he did of most of the fine old trees around his hospitable mansion. There are probably only three really distinct species of the Ivy in cultivation—namely, the Irish (*H. canariensis*), Asiatic (*H. colchica*), and the wild or English Ivy (*H. Helix*), and from these all our pretty varieties have descended. The most hardy, vigorous, and free-growing species is without doubt *H. canariensis*. On a future occasion I intend to notice some of the most characteristic and pretty varieties of Ivies in cultivation, and the best modes for growing them effectually. JAMES F. ROBINSON.

**Summer Border Plants.**—I have a border on which I wish to substitute annuals for ordinary bedding plants. How am I to proceed? Will they look well ribbon fashion? H. M.—[The commoner kinds of annuals would not be suitable for your purpose, as their duration is short; but by using such things as Mignonette, Stocks, Asters, *Saponaria calabrica*, *Phlox Drummondii*, *Nemophilas*, and some other very choice annuals, you might have a continuous supply of flowers throughout the summer. A few herbaceous plants, such as *Viola cornuta*, blue and yellow Cliveden Pansies, *Campanula carpatica*, might also be added. These would, however, hardly be suitable for a ribbon border, but by making a panelled border you could have a variety of plants and abundance of blooms. The front line might consist of blue *Lobelia*, and the back line some sort of *Pelargonium*. Between these two lines mark off the ground into a panelled or chain form, each link of which should be planted with one kind of plant only, but a distinct specimen may form a centre piece to the link, and a doubly planted line may separate the one

link from the other. The links may be circular, oval, square, rhomboid, or of any other conceivable form. The annuals just named do best when raised in heat, but the hardier ones will do very well raised on the open border, afterwards to be transplanted where they are to bloom. Mignonette, however, should be sown where it is to remain. Should some hardy Sempervivums be obtained they would form nice edgings, and are easily increased by means of seeds, leaves or offsets. *S. montanum*, *californicum*, and *tectorum* are amongst the best, and make good permanent and neat edgings throughout the year. *Calceolarias* in some places do badly, even under the best of treatment. For these you might substitute *Tagetes pumila*, yellow Pansies, and *Gazania splendens*, and where foliage is as important as flowers, yellow-leaved *Pelargoniums* answer the purpose very well.]

**A Flower Farm.**—That floriculture is becoming rapidly popularised in the new world will be sufficiently evident from the following account of the flower farm of Mr. Allen, of Long Island, sent us by a correspondent. There were eighteen acres of *Gladioli* in blossom, and perhaps your readers can imagine the mass of gorgeous colour which three hundred named varieties, planted to this extent, would make. Then, in addition to the three hundred named varieties, there was a bed of 3,500 seedling *Gladioli*—among them as fine specimens as can be found among the three hundred named varieties; and several that will become distinguished for their unique beauty. Then imagine ten acres of Lilies, a large proportion of which were in bloom. These embrace also about 15,000 seedlings. Here was to be seen the only *Leichtlinii* in bloom to be found in the country, it was said. Fifteen or twenty acres are cultivated in Tuberoses. Mr. Henderson's new dwarf variety is here—about half as tall in growth as the old sort.

**Rose Culture on the Pegging-down System.**—This system is easily understood. The shoots made last summer are pegged down in spring near the surface of the earth, while those that flowered last summer are cut clean away. In like manner, the pegged-down shoots that will flower throughout the coming season will be cut away at next pruning time, and the young shoots made this year from the central parts of the plant will be pegged down in their turn. By this system flowers and shoots seem to spring from the leaf-covered earth, and the pruning is simplified; we have merely to cut away the old shoots that flowered in the past year and peg down the young ones, shortening and thinning these last as each variety may require. This gives us a totally new set of fresh vigorous flowering shoots every year. By the old system we had no such advantage, and it was quite common to so badly prune Roses, by hacking away at old and new wood alike, that they hardly paid for root room.—V. E. R.

**The Blue African Lily (*Agapanthus umbellatus*).**—This is one of the most beautiful and useful of the Lily tribe, and one which, though commonly considered to be a greenhouse plant, will succeed well in a south aspect in the open air. There is a white and also a variegated variety of it too, both of which are well worth attention. I, however, find the blue kind the most useful, as it remains so long in bloom, especially when set in a partially shaded situation, or just screened from the parching rays of a bright sun. Like the Scarborough Lily (*Valloia purpurea*), it is very suitable for placing in a porch or balcony, as well as for conservatory decoration. All the varieties of this Lily flower when well grown in a mixture of equal parts leaf-mould and rich fibrous loam, to which may be added one part lime-rubbish mixed equally with sand. They are easily multiplied by division of the roots, after which they require to be set in a shady situation until they make fresh roots and growth. When established they will bear more exposure to light. I have grown the ordinary blue *Agapanthus* for fourteen years, and have found it to be a most valuable autumnal flowering plant both in and out of doors.—J. GRAMAM, *Woodcliffe Gardens, Rawdon, near Leeds.*

## NOTES AND QUESTIONS ON THE FLOWER GARDEN.

**Early White Arabis.**—In a garden at Feltham might have been seen in full bloom on the 27th of February, a number of plants of *Arabis albidis*, whilst a larger number of other plants of the same species of *Arabis*, growing in the same place, had scarcely developed flower-buds, and were at least four weeks later than the plants to which I allude. I conclude, therefore, that the latter must be seedlings from *A. albidis*, but much more precocious. Certainly to those who love to see border flowers in bloom as early in the year as possible, this new kind will prove most acceptable. A. D.

**New Pink Variegated Daisy.**—The double-crimson form of the Golden Bleached Daisy is one of the most charming and effective of all spring garden decorative plants; and it is most remarkable that ere this growers for market have not yet offered it to the public in quantities. In the seed grounds of Mr. R. Dean, at Bedford, may now be seen a true pink form of this plant, a sport from the crimson-flowered kind, and one which maintains its character, and makes a pleasing acquisition. There is also a white-flowered form sometimes to be met with, but with golden foliage the colour is not pleasing.—ALFRA.

## THE GARDEN IN THE HOUSE.

### PRESERVED ODOURS.

PERFUMES have been divided into orders—one list, drawn up by Linnæus, making nine classes, beginning with the aromatic, typified by Pinks, Laurels, and all the Labiate, and passing through the "sweet"—such as the Rose, Lily, Jasmine, Crocus, &c.; the ambrosial, such as amber, musk, and several exotic *Geraniums*; the alliaceous, of which the chief type is garlic, assafœtida, and several resinous gums; the fetid, like the goat; the repulsive, like the French Marigold, and several of the Solanaceæ; and finally the nauseous, like the flowers of the *Veratrum*, the *Stapelia variegata*, &c. The other and newer list has eighteen distinctive odours of perfume, beginning with the Rose as the type, which includes also the *Geranium* and the *Eglantine*; the *Jasmine*, including the *Lily of the Valley* and the *Ilang-ihlang*; and going on through the *Orange*, *Tuberosa*, *Violet*, *Vanilla* (balsamic), *Cinnamon*, &c., to the fruity, as *Pear*, *Apple*, *Quince*, and *Pine-apple*. The first step in the art of perfumery was simply to burn such sweet-smelling woods and gums as gave off a perfumed vapour, by which the gods were to be propitiated, inasmuch as by this they were fed. The last has been the thousand and one pretty applications put out by the leading perfumers of France and England; the French being in our day what the Athenians were in olden times, the great masters of the art, with both more taste as well as more skill than any of their rivals. All that they make in the way of perfumery proper, or of any description of scented toilette necessities, is of a better kind than anyone else can accomplish. Their soap is superior to ours; as much superior as the German is inferior.

But it is in perfumery proper, that which fills our scent bottles and scents our handkerchiefs, that Frenchmen, of all flower distillers, have made the greatest improvements. Thirty years ago there were neither so many extracts, nor so many flowers from which to extract, as now. *Eau de Cologne* from the city of a hundred odours, and *Lavender water* from the fields about London, formed the staple of the liquid scents in use. *Rondeletia*, sweet, cloying, sickly; *millefleurs*, more delicate; *Verbena*, coarse and overpowering; essence of bouquet, simply perfection, to this day unsurpassed—these were the principal extracts in the days when some of us were young; but since then their name has become legion, and a new perfume is now as much *de rigueur* for the season as a new colour or a fresh costume. The range of materials has been increased by the introduction of new flowers from abroad. A few years ago *Ilang-ihlang*, *Frangipani*, *Vitiver*, to mention no others, were as little known as the minor planets to the Greeks, or the spectroscope to the Chaldeans. With the marvellous facilities of distillation and the preservative properties of glycerine, both of present time and use, and with the cultivation of so many new exotics, a far larger field is open to the perfumer; and he has made the best of it. Yet there are certain things which baffle him. Not only that question of what is the real essence of odour, which we spoke of before, but also the power of fixing it in certain cases eludes the skill of the deftest distiller. The *Heliotrope* is our best example. No process known can imprison the fugitive scent of this delightful flower; and the only approach to it that can be had is by a combination of *Heliotrope* and *Bitter Almond*, which imitates it *tant bien que mal*. In spite of all that art and science can do, the only solid base of floral extracts remains with six flowers—*Orange flowers*, *Roses*, *Jasmine*, *Violets*, *Acacia*, *Tuberosa*. For England add *Lavender*. Of course there are the perfumed woods, such as *sandal wood*; the animal odours of *ivory* and *musk*; the automatic odours of *Cloves*, *Cinnamon*, and the *Labiate*; but in spite of certain extracts got from *Geraniums*, *Jonquils*, *Mignonette*, &c., the real mothers of our scent-bottles are the six we have detailed above.—*E. M. M.*

### BOUQUET MAKING.

YOUR correspondent "P. A.," when writing on cut flowers (see page 38), says the bouquet maker first lays the foundation with any small-leaved sprays by tying them together, and then taking a *Rose* or *Camellia* for a centre, proceeds to arrange the other flowers around it. May I ask your correspondent to be a little more explicit as regards the so-called foundation. I cannot understand how to put a large flower in the centre, that is, on the "foundation." Does your correspondent mean the fan-shaped bouquet? If so, I can understand him, as it is the old and still prevailing system in country markets to have a flat framework or foundation at the back; but I believe I am right in thinking that this old one-sided bouquet of the country cottager or industrious farmer's wife is not the bouquet of a Covent Garden Market artist and expert; those, if I am rightly informed, are made round and rather flat. I never saw one of them;

still I have made many bouquets that have been thought worthy of a better fate than to be thrown under the table even at Covent Garden; but if I can improve their form by a foundation of sprays, I shall be very pleased. An expert maker, it is said, will edge with Mignonette or Sweet Briar, or Lily of the Valley. This, again, is new to me. Edge with Mignonette, that is so brittle? Here I must allow the Covent Garden bouquet maker to be my superior. I always place Mignonette, Lily of the Valley, and the like more in between the other flowers, so that they may sit above the surface of the bouquet; by so doing they are not liable to be broken or lost. Sweet Briar undoubtedly is well suited for edging as well as for intermixing with the flowers. Such is my way, but I wish to learn. I can meet your correspondent on better terms when he says the expert artist will most likely throw into a vase, as a foundation, a handful of Sweet Briar, &c.; this is what I always do in the case of trumpet-shaped vases; indeed, it is impossible to keep short stemmed flowers up without such, especially when nothing but water is employed, but I always like sand, because in that case the flowers stay better in their places, and few of them are needed to furnish a vase. Ladies as a rule do not place a foundation or frame-work first in the vases, but put flowers first, and then sprays after. Hence the most charming and effective of the flowers often get lost in the bottom of the vase. I quite agree with your correspondent in reference to arrangement, but I cannot understand what is meant by a foundation, and common Box is not to my taste a suitable companion for a Camellia or a forced Rose.—J. T. MAES-GWYNNE.

[The foundation of a pyramidal hand bouquet should be formed with long wet bunch moss standing erect. It should be wetted a day or more before it is used, as in that case the tops get nice and green. It should be well wetted after it is put together; then the short-stemmed flowers derive moisture from the moss, which keeps them fresh. The centre flower should consist of a Camellia, Rose, Gardenia, Carnation, or anything in that way that is white. Lily of the Valley, Maiden-hair, and Mignonette should go round the second course, and Ferns with Poinsettia, &c., round the third or finishing course. A foundation for dishes should consist of moss, clay, or silver sand, with Box stuck about in sprays, or Lycopodium planted on the surface. For trumpet-shaped vases use Box, Asparagus spray, Sweet Briar, or any evergreen that will look well.—W. H.]

BASKET BOUQUET-HOLDER.

This simple and ingenious contrivance, recently figured in the *Revue Horticole*, is employed by some of the leading nursermen at Bordeaux for the safe transmission of bouquets, which, protected in this manner, may be sent by train or otherwise, perfectly uninjured, for hundreds of miles. The figures require hardly any explanation, showing, as they do, a neat wicker-work bouquet-holder, empty and open in the one case; and, in the other, closed upon the bouquet which it contains, and ready for the journey. It will be seen at once that a bouquet thus guarded is in no danger of being crushed or rumbled, and, moreover, escapes the withering effects of being brought into contact with the warm hand, as it is when carried in the ordinary way. Its freshness is further maintained and prolonged by surrounding the lower part of the flower-stems with damp moss. A piece of string, passed

round the "handle" of the bouquet and then fastened to the lower part of the holder, will keep the bouquet firmly in its place, and the holder may then be upset or even thrown roughly about without danger to its contents. The holder may be made in various sizes and shapes, to suit bouquets of particular patterns. That from which our illustration was sketched, measured a foot and a half in diameter and the same in height. We are not aware that this easily-made and useful little contrivance has yet found its way into this country; specimen patterns, however, can be obtained at the establishment of M. Cadeau, nurseryman and bouquetier, 58, Rue Fondaudé, Bordeaux.

Arranging Small Flowers.—I know that much difficulty is often found in arranging such small flowers as those of Violets, Hepaticas, Snowdrops, &c. The way in which I find them look best and easiest to manage is as follows:—I take a bundle or two of fresh-looking green Moss, and cut off the lower part so as to make the stems short; this I pack into a common saucer, till I make it quite a little mound of green Moss; I then take my flowers and tie them, say three in a bunch, with a little fine wire; this of course makes the stems stiff, which is what this small class of flowers require, to induce them to stand up firm in the Moss. Having placed them according

to my fancy, I then take a few fronds of Maiden-hair Fern, or any other kind that may be at hand, and weave them in through the flowers. The edge I generally finish off with Ivy-leaves, sometimes plain and sometimes variegated; of course Ferns or anything else can be used, but I like the Ivy, as it lasts so long fresh. If a little water be poured in through the Moss every morning, so as to damp it well, it is astonishing how long the flowers will remain fresh. The Maiden-hair may go off a little, but a few fronds can be easily put in, which will brighten it up and make it look

Bouquet-holder half opened.

Bouquet-holder closed and containing a Bouquet.

as fresh as ever. I did a little stand last week for the drawing-room, composed of double fresh Hepaticas, Snowdrops, Maiden-hair, and variegated Ivy leaves, which looked simple and pretty.—A. H., *Upper Norwood*.

Flower Gum.—This may be made by pounding white shell-lac very fine and mixing it with methylated spirit in a stone jar to a proper consistency, well shaking it up for half-an-hour, and placing it by the side of a fire to keep the bottle warm, and occasionally shaking it for about a day. Pure spirits of wine may be used, as it does not smell so strongly as that adulterated with naphtha. The former does not smell after it is dry and is much cheaper than the others. Keep the shell-lac in the water at all times until it is made up. The gum may be kept in any cool place and a little taken out as it is wanted, leaving the camel-hair brush in the gum. A good brush may be made of a bit of human hair placed round a stick fixed thereon by means of a bit of flexible wire. In gumming never fill the brush too full, and the petals should be gummed close to the tube.—W. HOWARD.

Acacia Lophantha.—I have a plant of this which has been growing in my dining-room throughout the winter, and is now well furnished with its delicate and elegant leaves. I bought it from a hawker last September, and have never had a more satisfactory window plant.—MARTIN A. S.

Drills for small Seeds.—Making drills for small seeds is best done by pressing the edge of a lath or thin board into the previously-smoothed soil. This makes a drill that is perfectly smooth at the bottom—where the seeds can be distinctly seen, and if the sowing is not properly even it can be made so, which cannot well be done in a rough drill made by scratching the soil.

## THE FRUIT GARDEN.

### MELON CULTURE IN COOL PITS.

The development of the bedding or massing system of tender plants in flower gardens has rendered the erection throughout the country of large numbers of cheap, shallow (comparatively speaking), cool pits necessary, in order to provide for the wants of this class of plants in the early spring months, and it is concerning the utilisation of this class of structures I now wish to speak. The facilities for the culture of early Melons in the shape of large quantities of stable dung, or artificially heated structures adapted to their wants, do not exist in all gardens; but everybody who has a pit or two for bringing on bedding plants has the means within his reach of securing a supply of good-flavoured Melons at least in August, September, and October. In Melon culture, without much artificial heat, one of the chief elements of success lies in the selection of suitable kinds for the purpose; and one of the best varieties I have hitherto tried under cool treatment is Gilbert's Victory of Bath. It is a green-fleshed kind, possessing a hardy, vigorous constitution, sets freely, is of good flavour, and, I may add, is first-class in every respect. Amongst scarlet-fleshed kinds we have hitherto found Scarlet Gem most useful, the only objection to it being its size—it is rather too small. I, however, intend trying this year Munro's Little Heath. This, judging from its description, should be the very thing we want for summer culture.

The end of March is early enough to make the first sowing, to have strong plants to turn out the first or second week in May, and a pit may generally be spared by that time, as many of the harder kinds of bedding plants will then be hardening off in the open air. Another sowing may be made about the middle of April, and a third about the end of the month, will furnish a succession of plants for planting all the pits as they become vacant. When the first pit is clear of bedding plants, clear it out and have it thoroughly lime-washed, and filled to within a foot of the glass with any fermenting materials that may be at hand. Stable dung is the best, treading it well down; the object is to get a nice root warmth to start the plants till we have warm summer weather. When the heat has subsided a little—and as the bulk is not great it is not likely to be violent—pack into the centre of each light about three barrow loads of good strong turfy loam, levelling a little of it down to the back and front, in order to keep down any noxious gases that may arise from the fermenting material. In two or three days, when the soil is nicely warm, the plants may be put out, and unless the lights or sashes are very large, one plant in the centre of each light will be sufficient. There is never anything gained by crowding, but rather the reverse. The pits must be matted up at night, unless the nights are quite warm in July. The after-management is very simple, the great secret of success being, timely attention to their wants, which may be shortly summed up thus:—

In planting take care that there is room for the full development of the foliage, without coming into contact with the glass, and then, if the ventilation is attended to, there will be no fear of scorching. Attend frequently to the stopping and pegging out of the shoots; to allow them to grow into a thicket, and then to be compelled to use the knife, to amputate strong growths, is bad. Earth them up as soon as they have fairly begun to run, pressing down the soil rather firmly. A firm soil checks grossness of growth, and promotes fruitfulness. Sprinkle them about half-past three o'clock on the afternoons of fine days with water that has stood in the sun all day, shutting up at the same time.

When a sufficient number of fruit for a crop is set (and with summer Melons there is not much difficulty about this matter, for bees and insects generally perform that part of the work after May) cut off all that are not required, and mulch the beds over with short manure. During the time the fruit is swelling, Melons take a good deal of nourishment, and the mulching will be a great support to them. Red spider is the greatest enemy with which Melons have to contend in the way of insect pests, but by taking care that the pits are cleansed and whitewashed annually, sprinkling, and shutting up early on fine days, giving air early in the morning, to be followed by a free circulation, but no shading, and moderate

root watering, with water from which the chill has been taken—if all these things are attended to there will not be much trouble with regard to red spider. Whenever, however, it has by any neglect or oversight effected a lodgment, the best remedy I have ever found for it is, after the morning ventilation has been given, on a warm sunny day, to close the pit, having previously thoroughly saturated its atmosphere with clean soft-water, by syringing the walls and every available part of the interior, so as to fill it with a dense vapour, and to keep it closed several hours, if necessary repeating the syringing and slightly shading if the day is very hot. The theory upon which this cure depends is this: red spider thrives amazingly in a high dry atmosphere, but moisture in any state it abhors; and a close, warm, moist atmosphere is death to it. I have always found this remedy efficient if taken in time, in the case of both Melons and Cucumbers. Of course when the leaves are destroyed by it nothing will resuscitate them. The two most fertile sources of red spider on any plant are, extreme dryness either at the root or in the surrounding atmosphere, and deficient ventilation. As the fruit approaches maturity, less moisture must be given, especially at the roots; although, if the weather is very bright, a light sprinkling or dewing over with a fine rose in the afternoon will help to keep the foliage healthy, and without healthy foliage finely-flavoured fruit cannot be obtained.

E. HOBDAV.

### RENOVATING OLD VINES.

ABOUT six years ago an amateur consulted me about a house of Vines that were in a most unsatisfactory state. They were from fifteen to twenty years of age, and ought to have been just in their prime. Before consulting me he had been advised to root them up and plant young ones. I examined the border, and found, as I expected, the roots had travelled beyond it into the cold wet subsoil, which had brought on shanking to a most alarming extent. The old border, which was in a bad state, was entirely cleared away, saving as many as possible of the roots. The drainage was seen to, and a new border of chopped turf (in which a little bone-dust was incorporated) was made, the roots were shortened and carefully laid out, and the border was well mulched with manure; the rods inside the house were thinned out and shortened a little. They were allowed to break almost naturally the next season, and the result was a crop of good fruit with scarcely a shanked berry; whilst before they were lifted it was no uncommon thing to see whole branches go off. Many houses of old Vines have been cleared off, and a scarcity of Grapes submitted to by the proprietors whilst young Vines are getting up that might have been got into good condition without sacrificing a crop. There are old Vines enough in the country to prove that, under ordinarily favourable conditions, the Vine will live and be fruitful to a vast age. There certainly is never an "effect" without a cause; and when a house of Vines, or indeed anything else, turns out unsatisfactory, before any reliable data can be arrived at sufficiently conclusive to suggest a remedy, the cause of the disaster should be ascertained. Old vines may be rooted out and young ones planted; but if the same causes continue to operate, the chances are that the young Vines at no distant period will go the same way as the old. The disease called "shanking" is caused by a deficiency in the supply of nutriment at a critical period of the growth of the fruit, and this deficiency frequently arises from the roots penetrating into a cold subsoil. Having travelled beyond the prepared border, they become in an ungenial soil sluggish and inactive, and are consequently unable to supply the heavy demand made upon them, and the fruit fails.

Another fruitful source of shanking is making the borders too rich and heavy, and neglecting the drainage; and I have investigated one or two cases where I was satisfied it arose from lack of moisture at the root. Extremes of all kinds are bad. Vines in dry seasons should be well supplied with water, especially in shallow borders. The exhausting influence of a heavy crop of fruit for a series of years, especially in late houses, where the fruit is required to hang a long time, tends to induce shanking; and it is the knowledge of this fact that has induced many good cultivators to cut the Grapes when ripe, and preserve them by inserting the ends of the shoots in bottles of water, thus relieving the Vines of their heavy burden, to their manifest advantage. I lately had an opportunity of visiting one of our best Grape-growers, and, in a conversation about old Vines, he remarked that one of his best houses last year was furnished with the same old Vines he found there more than twenty years ago, but of course they have been thoroughly well managed, both roots and branches. In making a Vine border, the first requisite is thorough

drainage; the next is a good supply of chopped turf from an old pasture. This chopped turf formed the staple of all the best Vine borders I have ever seen; and I believe very good Grapes may be grown in it alone, without any addition whatever. Of course I am not against adding crushed bones where necessary, or, if the loam is heavy, old mortar or charcoal may be added with advantage. The only way of keeping Vines in a good bearing condition for many years is to look well after the roots, for when any falling-off is observed, there generally the cause must be sought for, and the remedy of lifting and shortening the roots applied, adding at the same time a further supply of chopped turf. The majority of the Vine borders must of necessity be less than twenty feet in width; but the roots, unless they meet with an impenetrable barrier, wander on until they get beyond this limit, and soft and spongy surpawood, with other evils, soon follow. Of course, I know there are places so favourable for Grape growing that almost without any extra care in this way good Grapes are grown.

I knew a gardener at an old abbey in the south of England, years ago, who always annually opened his Vine borders, and ran in such a dressing of pig-dung as would have frightened many people; but the soil was very porous, and in all probability the principal roots were many yards away, revelling among the bones of the monks interred there centuries before, for the Vines were very old, and always bore well. I remember also more than twenty years ago visiting a garden in the North of Ireland, where the Vine borders were ridged up like the other portions of the garden (of course, the roots were gone out of the way of the spade), and still fair Grapes were produced. These, I admit, are exceptional cases, which only go to prove what an accommodating plant in some soils and situations the Vine is. Some years ago, I had an early viney under my charge, where the Vines

were confined together inside the house in a very narrow border, not more than 5 feet or 6 feet wide, and very good fruit of Hamburgs and Muscats were grown; but every autumn the old soil was taken off the surface down to the roots (of course, a few of the small roots were inevitably destroyed), and the space filled up again with chopped turf and manure. Inside borders may be made richer than would be safe for outside ones; there is then not the same necessity for feeding them to such an extent with strong liquids, which I have seen in more than one instance act injuriously, especially in the colouring and finishing process. It is also desirable to lead up a new rod occasionally; it infuses fresh life and vigour into old Vines to be gradually renewed in this way, as when the old Vines have been pruned many years on the spur system, they are apt to look ugly and cumbersome, and the bunches become smaller. Therefore, if larger bunches are wanted, a continual but gradual accession of young rods will render the produce as large, perhaps larger, than that obtained from younger Vines, and the flavour of the fruit from established Vines is generally admitted to be superior to that of fruit got from young ones.—*Field*.

**Seacliffe Black Grape.**—I am glad to see that Mr. Fish, in his notes on the gardens at Drumlanrig, still persists in calling the famous variety of Grape which he saw there by the distinguishing name of Seacliffe Black; the more so as we have been told in the pages of a contemporary that it is synonymous with the Gros Guillaume. Having seen the Grape which Mr. Fish so justly admires, permit me to corroborate his opinion as to its being distinct from, and vastly superior to the last-named variety, or what is now considered to be identical with it, viz., the Barbarossa. Grapes, like other fruits, vary much according to the favourable or unfavourable

### A FINE PEAR TREE.

THE Pear tree of which we this week give an illustration is one of the largest we have seen, and is a fine example of training. It grows against a wall in the gardens at Ashridge Park, Berkhamstead, and our representation is reproduced from a photograph taken for THE GARDEN. The tree is of the Passe Colmar variety, and as far as the head gardener, Mr.

A fine Pear Tree at Ashridge.

Sage, can ascertain from one of the old garden men who assisted in planting it, is forty-six years old. It is 56 feet long and 14 feet high, is kept close to the wall, pruned on the spur system, and bears abundantly.

**Wall-fruit Prospects.**—The few mild, sunny days which we have had have swollen up the flower buds of Peaches and Nectarines to the bursting point, some of the earlier sorts being, in fact, quite open. The wood looks stout and well ripened, and there is at present every indication of good wall-fruit crops. The dull, cold month of February proved most effective in checking that early expansion of the flowers that seemed to be so close upon us at the end of January, and now there is hope that the bloom will escape injury. I have growing on the front of my cottage, facing the south, a large tree of the Hemskirk Apricot, a goodly number of the blooms on which were expanded on the 2nd inst. It is protected by a projecting eave 20 inches in width, which is, of course, permanent. I incline to the belief that if all our fruit walls had permanent projecting eaves of about 12 inches, the trees would suffer no injury in growth, and would be greatly protected from frosts.—A. D.

**Vines.**—Some of the young leaves of my Vines have a withered, blighted look, like those which I have sent you. Can you kindly tell me what ails them? P. L.—[The Vine shoots sent for inspection have all the appearance of being scorched, either by water being poured on hot flues or pipes, or by a hot sun in the middle of the day, acting on the glass without ventilation in the house. The appearance which the foliage presents would likewise be caused by being frost-bitten, if any panes in the glass were broken, or where the temperature of the house fell below the freezing point. I do not

think that Vine mildew has caused the injury, for I have never seen it appear so early, and the withered foliage has not that peculiar scent which is so indicative of mildew. The only remedy, if the foliage and young bunches of fruit are much injured, is to keep the house at a low temperature until fresh foliage appears, when the temperature may be gradually raised, for the purpose of ripening the wood properly for a crop next year.—WILLIAM TILLERY.]

**Spur-pruning of Fruit Trees.**—Overbearing, as regards fruit, is an evil to be guarded against as much as possible, as it enfeebles the constitutions of trees and brings on premature decay. Spur-pruning and thinning of the fruit are the best means of preventing this. I would, therefore, strongly advise that all trees should be carefully and judiciously spur-pruned, when the state of the weather permits it to be done. Through the almost total neglect of this, one of the most important operations in fruit-tree culture, we generally see trees one year bent to the ground with the weight of fruit, and the following year no fruit at all; and this goes on year after year. One season a heavy crop of inferior fruit, the next year none. When the trees bear these heavy crops, the fruit is never so fine as it would be if it had been properly thinned. The thinning of the blossom and fruit is an operation which cannot be properly carried out to a very great extent, as it is in general a busy season when such work requires to be done. Spur-pruning should, therefore, be regularly attended to and carefully performed. When the spurs are crowded, all the longest and weakest should be cut clean away, and on those that are left the buds should be well thinned out; all the weak buds and those on the ends of the spurs should be cut clean off, leaving the roundest and most plump, and taking particular care of those at the base of the spurs. When pruned, the buds should be left at such a distance from each other that the sun and air should have full influence on them. On old trees that have been neglected, spur-pruning can hardly be too freely carried out.—M.

**Manure for Fruit trees.**—Woollen rags, sprinkled over with soda or potash, and then allowed to decompose in heaps, have been recommended by the late Dr. Wittewaall, as the best possible manure for fruit trees. In a number of experiments made by him to test the comparative merits of woollen rags so prepared and ordinary stable-manure, he found that young trees especially grew far more vigorously when treated with the former. His mode of applying the rag-manure was to place 5 or 6 lbs. of it around each tree at a depth of 4 inches from the surface, covering it in with ordinary soil. Some soil was also placed over the roots, in order to prevent the rag-manure from coming into direct contact with them. The results of his experiments appear to have satisfied him, in every case, of the immense superiority of the rag-manure.

**Vines in Pots.**—I have some Vines in 12-inch pots just beginning to grow. How am I to feed them during the season? I have a good supply of sheep's dung and liquid manure. How many bunches should be left on each plant, and will the plants be available another year?—M. RYAN. [Plunge your pots half their depth in a bed gently heated, if possible; but if that cannot be done, as they are fairly started, the loss will not be great. Put a mulching, consisting of equal parts sheep's dung and loam on the surface of the pots, and after that has become exhausted through repeated waterings, use occasionally weak manure-water, made from sheep's dung, until the Grapes begin to colour, when pure water only must be given. From six to ten bunches may be left on each Vine, but seven is the ordinary number, though strong plants, liberally fed, will ripen off well from eight to ten on each Vine. If, however, you intend to crop the same Vines a second season, or want them for planting out permanently, take only about five bunches off each Vine. Under all circumstances, good, healthy, and clean foliage is of primary importance.]

## NOTES AND QUESTIONS ON THE FRUIT GARDEN.

**Pigs in Orchards.**—Among the points of interest discussed at the annual meeting of the Ohio State Horticultural Society, was the use of pigs in Apple orchards as cheap and effective cultivators of the soil, and destroyers of worms, grubs, &c.

**Pears on the Quince.**—Pears are commonly grafted upon a Quince stock; but it is supposed that there are more than forty varieties which refuse this union, and which are therefore managed by double grafting upon a Pear stock of a proper sort which has itself been grafted upon the Quince. Professor Decaisne on the first trial of such an experiment under his own observation succeeded with twenty of these antipathetic varieties without difficulty; but some (among which are Clairgeau and Beurré Bosc) obstinately refuse to unite with the Quince stock.

**Seedless Apple.**—A correspondent has sent to the *Gardener's Monthly* two samples of a seedless Apple, which he considers a valuable acquisition. It is a regular and prodigious bearer, long keeper, and vigorous grower; it is worthy of general cultivation, and saves much time in preparing it for the table, as it needs not to be cored. The flower is without petals, and apparently without pistils. The flavour is excellent, something akin to that of a Newtown Pippin, from which it may be a seedling. It is, however, smaller than an average Newtown.

## "BIG TREES" IN CALIFORNIA.

### THE THREE SISTERS.

ONE of the greatest curiosities in California, and, indeed, of its kind in the world, consists of the Big Tree grove, situated on the space between the middle fork of the Stanislaus and the Calaveras river, about twenty miles east of Mokelumne Hill, and at an elevation of 4,750 feet above the level of the sea. The number of these trees, a species of Redwood bearing the botanical name of "Sequoia gigantea," is ninety-two, ten of which are at least 30 feet in diameter; eighty-two having a diameter varying from 15 to 30 feet. Their height, as they now stand, ranges from 150 to 327 feet, the tops of many of the more aged having been broken off by the tempests or snow. The original height of some is believed to have been over 450 feet, and their diameter at least 40 feet. Through the prostrate trunk of one of these trees, which has been hollowed out by fire, a man can ride on horseback for a distance of 75 feet. Some years ago one of the largest of the number then standing was cut down, with a view to secure transverse sections of the trunk for exhibition. It was 92 feet in circumference and 300 feet high, and it required the constant labour of five men for twenty-two days to fell it—the work being accomplished by means of boring with long augers. At the same time, another tree of nearly equal dimensions was stripped of its bark for a distance of 116 feet from the ground, a lofty staging having been erected about it for the purpose. The bark was taken off in longitudinal sections, which, being afterwards replaced in their proper order, reproduced the exterior of this giant of the forest—having much the appearance that it presented while growing. Such was the wonderful vitality of this tree that many of the branches still continued green for seven or eight years after this extensive mutilation. By carefully counting the concentric rings, denoting the annual growth of these trees, their age is found to vary from one thousand two hundred, to two thousand five hundred years. In some places these trees are separated by spaces of several rods, while in others they stand quite close together, some being united at the roots, and having grown almost into one, which, when they first sprouted, were 20 or 30 feet asunder. Our illustration represents one of the most beautiful and singular groups in the Calaveras grove, known as the "Three Sisters" or the "Three Graces." The name is well applied, and suggests itself at the first sight of these tall graceful trees standing side by side, with their branches intertwined, as in an affectionate embrace. Their similarity in size and appearance is very remarkable, each being in fact the counterpart of the other two. They measure nearly 295 feet in height, and the circumference of the three together round the base is no less than 92 feet.

The Calaveras grove, though really one of the most remarkable, and, from its accessibility, by far the most frequented, is not the only one in this State, there being three groups of big trees in Mariposa, one in Tuolumne, and another in Tulare county, with, perhaps, others not yet discovered in the adjacent but less explored portions of the Sierra Nevada.

## THE VOICE OF SPRING.

HARK! the Spring again  
From their bowers hidden  
All her tender train  
Blithesomely has bidden.

"Wake, O wake! for now at last  
Cruel Winter's reign is past."

See her little babes the buds,  
Rosy-red with innocent sleep,  
From their cradles in the woods  
Pretty wonderers upward peep  
Through the unfathomed firmament.  
Now with earthward gaze intent  
Eager mark how far below  
Golden flowers and flowers of snow  
Gladden all the garden-row,  
Or, like stars on quiet seas,  
Daisies light the verdant leas;  
Whilst the faithful robins sing,  
"Cruel Winter turns to Spring."

—A. P. Graves, in Fraser.

“BIG TREES” IN CALIFORNIA (THE THREE SISTERS.)

## THE DARNEL GRASS NOT POISONOUS.

In a paper on *Lolium temulentum* (Darnel Grass), read by Mr. A. S. Wilson at the January meeting of the Edinburgh Botanical Society, the author remarked that the purpose of his investigations was to discover if there are poisonous qualities in the seeds of the Grass called Darnel. The seeds of this plant appear to have been objects of alimentary aversion from remote times. To what Virgil refers in the expression, "Infelix Lolium" (Georg. B. 1. 153) cannot now be determined. It is uncertain, indeed, if he refers to Bearded Darnel as a single plant, or includes various Grasses. And that the poet-farmer had in his mind rather the conception of troublesome weeds than of poisonous seeds, seems probable from his conjoining wild Oats with the Darnel ("Infelix Lolium et steriles dominantur avena"). Pliny speaks ("Nat. Hist." 18, 17) of *Lolium* and other weeds as being the pests of the corn fields, but does not allude to poisonous properties. If the old Greek and Roman farmers are truly represented by Columella and Theophrastus, they entertained the notion that the cereal Grasses were constantly changing into each other, and that the damaged seeds of these gave rise to Darnel.

The present position of the question may be seen from the following references. The name *temulentum* signifies intoxicating. Lindley, in his "Medical and Economic Botany" (2nd ed., p. 27), describing this Grass, says, "Grains narcotic and acrid, producing fatal consequences when mixed with flour. N.B.—This is the only authentic instance of unwholesome qualities in the order of Grasses. The cases mentioned in the 'Vegetable Kingdom' are all doubtful." In the "British Flora," Hooker tells us (1th ed., pp. 16, 19) "the ancients as well as the moderns attributed poisonous qualities to the *L. temulentum*, and even now it is believed in some countries that the Wheat changes into Darnel." He further tells us that the name *Aira* (from *airo*, to destroy) "was anciently applied to the *Lolium temulentum* (Bearded Darnel) on account of its injurious effects." In Balfour's "Class Book of Botany," paragraph 1539, we read, "*Lolium temulentum*, Darnel Grass, supposed to be the Tares, *Zizania*, of Scripture, has been said to be narcotic and poisonous, but this has not been fully proved." Bentley remarks in his "Manual of Botany" (p. 697), "Almost all Grasses are wholesome, but one or more species of *Bromus* have been reputed erroneously to be purgative, and one, *Lolium temulentum*, is said to be narcotic and poisonous. The powerful properties of the last Grass would appear to be due to its becoming ergotized, as its described effects upon the system closely resemble those produced by the common Ergot." In Lawson's "Agricultural Manual," article "*Lolium temulentum*," it is stated that "the seeds, if very abundantly mixed with wheat and made into bread, prove injurious to health, causing delirium and stupefaction." Under "Darnel," the "Imperial Dictionary" says, "The *L. temulentum*, or Bearded Darnel, is the only poisonous British Grass. It is said to be the infelix *Lolium* of Virgil, and the Tares of Scripture. Its properties are said to be narcotic and stupefying." Archbishop Trench, in his "Notes on the Parables" (Parable of the Tares) also accepts the dogma of the toxic quality of the Darnel.

On the other hand, the writer of the article Darnel in "Chambers' Encyclopædia," says:—"It is asserted that very recent researches on the continent have completely established the perfect harmlessness of this Grass and of its seed, and the effects which have been ascribed to it must, therefore, be regarded as proceeding from grain injuriously affected in some way by bad weather." These researches I have not seen.

Through the kindness of Professor Balfour, I obtained a few seeds of Darnel from the Royal Botanic Garden, Edinburgh. To guard against accidents, some of the best ripened of these, stripped of the husk, were planted in pots in which they stood during the winter (1871-2). The plants were transferred to the open ground early in spring. They grew remarkably well, appeared unchecked by transplanting, and threw out from ten to fifteen stems each. The rest of the seeds were sown in spring. But as they were not well ripened, only about a score of plants appeared. These did not tiller so well as the former, and although some of them attained a greater height, the spikes were not so well developed. The average height of the stems was about three feet. The best had from sixteen to nineteen spikelets, and the best spikelets had nine fertile florets or seeds. Into eight of the flowers when open, some of the spores of a fungus growing upon the ergot of Oat-grass (*Arrhenatherum bulbosum*) were introduced in a fresh condition. But none of the seeds so treated were ergotized. Although superabundance of moisture has been thought to favour the somewhat uncertain cause of ergot, yet notwithstanding the presence of this agency in 1872, the grasses in general were much more ergotized in 1871. And not above two dozen kernels of my Darnel were affected.

The very imperfect microscopic analysis which I have been able to

make of the Darnel, points to the possibility, if properly examined and tested, of arriving at the whole chemistry of such a fruit. In this way I have compared the Darnel seed with the seeds of several other Grasses.

The author then gave a detailed description of the microscopical structure of the Darnel seed, and compared it with that of Wheat and Barley. He said:—"The grains of Darnel experimented with were partly ripe and partly slightly unripe; they were air-dried and may have contained about ten per cent. of water. Ergotized kernels were rejected. It may also be noted that the quantities eaten were written down immediately on being taken in case of fatal consequences. The result was added a day or two after.

1. Two grains (eight ripe kernels) were reduced to meal in a mortar, mixed with cold water and drank, Sept. 30. I felt no symptoms of any kind.

2. Before breakfast next morning I pounded four grains (sixteen kernels) mixed with water and drank as before. No symptoms experienced.

3. I next ground a considerable quantity of the seeds. The paleæ were separated from the meal by a pepper-box. The meal contained nearly all the bran. It has a slightly yellowish tinge and is whiter than ordinary oatmeal. Of this Darnel meal I baked a cake of 100 grains, dividing it into eight parts. Two of these parts (twenty-five grains) I ate before breakfast, Oct. 8. The taste is similar to that of well-baked Oat-cake. Towards night I fancied that I felt a slight grinding sensation in the stomach. What I had for dinner might have produced this; it lasted only for a few minutes. There was no giddiness, nor any other symptom.

4. Oct. 10. Ate fifty grains more of my Darnel cake. Experienced no peculiar sensations of any kind, either in the stomach, bowels, or head.

5. Oct. 15. Made 100 grains of meal into pottage. It thickens about as much as Wheat-meal; is of a glaucous consistency; the colour like Rye-meal pottage; with a taste not much different from Wheat-meal pottage, and certainly anything but "acid." I ate the 100 grains with milk. No symptoms of any kind were experienced.

6. Thus far finding nothing poisonous, and knowing that in remote times the husks or paleæ of the cereal grains were incompletely removed from the meal, which might thus contain husks of Darnel, I tested their husks. The husks of Darnel, it may be stated, correspond to those of Barley and Oats, not to the bran of Wheat and Rye. Of these husks 91 grains (the husks of about 100 seeds) were beaten up in a mortar with 70 grains of Darnel meal. And as Lindley and others speak of fatal consequences resulting from Darnel mixed with Wheat flour, a small quantity of whole red Wheat meal was added to the not very tempting mixture. Of this I baked an unfermented cake, Oct. 17. Ate one-fourth of this cake, containing 23.5 of Darnel husk, 17.5 grains of Darnel meal, and about half an ounce of Wheat meal. No symptoms followed.

7. Oct. 18. Ate part of the remainder of my cake before breakfast and part after. The amount of husk was 70.5 grains, and of Darnel meal 52.5 grains. In other words, the husks of 2,000 seeds, and the meal of 262. No sensations or symptoms of any sort were experienced.

8. I next baked 310 grains of Darnel meal, equal to about 800 seeds, with yeast in the usual way in which wheaten bread is fermented and baked. Probably being whole meal it did not swell much in baking. It behaved in a manner similar to whole Wheat meal. The colour is dark brown. Rather too much yeast and salt had been used, so that the taste was less agreeable than it ought to have been, but still nowise "acid." Oct. 27. Ate two slices with butter at breakfast, containing about 12 grains of dry meal. I was in no way aware of having taken anything peculiar.

9. Next day I ate before breakfast the remainder of my Darnel loaf, containing of dry meal about 318 grains weight. No peculiar sensations either in the stomach, bowels, head, or elsewhere were experienced.

Thus, between the 30th September and 28th October I ate 561 grains of Darnel meal, equal to about 3,300 seeds, and 91 grains of Darnel husk, equal to the husks of about 3,100 seeds. The doses varied from 2 grains to 218. In my case, therefore (not to generalise), Darnel in such doses is not justly called "*temulentum*," its seeds and husks are not "infelix," are not "narcotic," are not "acid," are not "unwholesome," are not "injurious," do not cause "delirium," do not produce "stupefaction," and are not "poisonous" nor productive of "fatal results."

Whether the poisonous qualities attributed to Darnel resided in the ergotized seeds of this and the many other grasses which infested the ancient corn fields, is a much more difficult inquiry.

## THE PROPAGATOR.

### THE ART OF GRAFTING.

**FLUTE-GRAFTING.—GENERAL DIRECTIONS.**—The name of flute or whistle-grafting has been given to this method in consequence of the resemblance which exists between the manner in which the bud is detached and the means employed in making rustic flutes with tubes of bark taken from a branch in full sap. At present this mode is not much used in nurseries. Although it has been superseded by more expeditious methods, some persons still use it in propagating the varieties of the walnut, the chestnut, the mulberry, the fig, and the cherry. The season for flute-grafting is in spring, when the sap has begun to flow. It can also be carried on towards the end of summer, before the new generative layers are dried up by the cessation of vegetation. There are two principal methods of flute-grafting, in both of which the scion is prepared in the same manner. The scion (A) is a portion of bark of a tubular form, furnished with at least one bud. It is detached from the scion-branch by making, in the first place, a circular incision with the grafting-knife about an inch above the bud, and another at the same distance below it. These two incisions mark the length of the scion. A longitudinal incision is then made from one to the other on the side of the branch opposite the bud. The base of the leaf-stalk attached to the bud is then seized between the finger and thumb, and the portion of bark included between the incisions dexterously detached. Should there be any apprehension of

Ordinary Flute-Grafting.

Flute-Grafting with strips.

tearing the fibres—commonly called the germ or root—of the bud, the bark may be raised with the spatula of the grafting-knife. The scion is then applied to the stock in the place of a cylinder of bark of the same length, which is removed at the same time. The operation is best performed in calm weather, in order to avoid injuring the internal layers of the subjects by exposure. The practice of trimming the stock beforehand, with the view of promoting the union of the graft, is a faulty one. It is more rational to graft first, and to head down the stock afterwards when the union of the parts is ascertained. A stock in a young and herbaceous state is better adapted for flute-grafting than one which is old or hardened; and a stock which is very large should be grafted on its branches rather than on the stem. When strips of bark are used to fill up any vacancies not covered by the scion, it is seldom required to apply mastic to the joinings.

**ORDINARY FLUTE-GRAFTING.** The scion (A) is applied to a stock (B), which has not been previously headed down, in the place of a cylinder or pipe of bark of the same length, and which has been removed in the same way. It is placed so that its bud may be exactly underneath a bud on the stock. This bud will attract the sap to the graft, and thereby promote its taking. It is then bandaged, and cold mastic applied to any exposed parts of the joinings. Should the diameter of the scion exceed that of the stock, that is easily remedied by cutting off from the scion a longitudinal strip of bark equal in width to the difference. On the other hand, should the dimensions of the tube of the scion not correspond with those of the stock, the deficiency is made good by leaving on the latter

a strip of bark of sufficient width to fill up the space not covered by the tube of the scion; or, if the bark of the stock has been taken off in a complete ring, a strip of bark of suitable size can be inlaid on the bare part.

**FLUTE-GRAFTING WITH STRIPS.**—The scion having been prepared as in the preceding case, the bark of the stock is cut in longitudinal strips (F) attached by their bases. When the scion is quite prepared, these are turned down, and the scion is at once placed on (at E). The strips of bark are then brought up over it (as at G) and the whole bound round with a bandage. This process permits us to detach the scion without leaving the wound on the stock too long open, and also to prepare the stock before the scion has had time to flag. These strips also serve to cover bare places that occur when the scions are not wide enough. We practise a mode of flute-grafting with double strips. In this the stock is amputated, and both stock and scion are of the same diameter. The bark of both is cut in strips and turned back, and the wood that was under the strips of either stock or scion is cut away. The scion and stock are then placed end to end, and the strips of bark brought back over each and bandaged. This method is quite original.

**TREATMENT AFTER FLUTE-GRAFTING.**—As in every kind of grafting, the bandaging must be looked after, and not allowed to become too tight, and a prop or stake higher than the graft must be affixed. If the head of the stock is overloaded with branches, some of them must be cut away. The manner in which the stock is finally headed down depends on the nature of the graft: if it has been made with a pushing bud, the stock is cut away by degrees down to four inches from the graft—not commencing to do so, however, until the union of the parts is ascertained; if the grafting has taken place in the course of the summer, the heading down of the stock is deferred until the following spring, when it is performed by a single cutting.—*L'Art de Greffer.*

### NEW ROSES OBTAINED BY GRAFTING.

From a report made to the Royal Institution of Venice by Professor Di Visiani and Doctor Zanardini, who had been commissioned in last August to make inquiries into the matter, we extract the following:—"In the month of September, 1871 Signor Zea, residing at Venice, performed three experiments with the Roses known to gardeners under the names of Malmaison rubra, Colonel Poissy, and Cardinal Patrizio. The grafts were taken from flowering branches of the varieties above named; they were shield-budded, and the sutures fastened round with strips of lead sealed at each end with sealing-wax, bearing the impress of our seal. All the grafts took well, and two of them bloomed in May last; we have waited in vain for the flowering of the third, the young shoots having been destroyed by insects. But the two first experiments sufficed to show that the blooms were very different in form, in tint, and in certain markings of a very intense colour. After careful investigation, and having put numerous questions to the operator, we received from him the following statements:—1. That in the second, and still more so in the third year, when the grafts become stronger and more vigorous, the markings are much more conspicuous and the colours generally brighter, as we saw in other older varieties obtained by him in the same way, the markings of which were very decided and the colours truly brilliant. 2. That the varieties so obtained remain constant when layered or grafted by cleft-grafting or shield-budding in the ordinary way. 3. That if they are lost they can be reproduced by repeating the operation under similar conditions. 4. That all varieties of Roses do not give equally good results. Some give varieties of finer colour, and better marked than others. Being unacquainted with those portions of the process beyond that of ordinary shield-budding, we feel bound to confine ourselves to a simple attestation of the fact that the blooms seen by us were very different from those on the branches from which the buds were taken. Signor Zea, in his letter, has shown himself disposed to communicate his method of operation to this institution. This would be very desirable, as it is only when the process is known that we can look to science for a possible explanation of the results so obtained."

### PROPAGATION OF CAMELLIAS.

CAMELLIAS may be propagated by cuttings at any time; the most favourable season, however, is during the month of January. The cuttings are usually taken from plants of Camellia japonica, which are cut back every third year in order to furnish vigorous shoots. Plants which are intended to be grafted also afford many very good

cuttings. In all cases, select vigorous and healthy shoots of the current year, rejecting unreservedly any which have diseased leaves or any other imperfection. Having carefully washed them, cut them with a very sharp knife into lengths of from 2 to 4 inches, preserving one or two leaves, and making the lower cut, if possible, at the base of a leaf or bud; then make a longitudinal incision about a line in length on the base of the cutting. Have some clean, well-crooked, shallow pans ready, containing about 1½ inch deep of good sandy peat-soil, on which place a layer of white sand about an inch in thickness. Fill the pans with the cuttings, set very close together in two or three circular rows, and leaving the centre of the pan empty. Plunge the pans under cloches or frames in a house in a bottom heat of 70°, keeping the external air excluded from the cloche or frame, and the internal air and the leaves of the cuttings constantly moist. Cuttings treated in this way will soon make good roots, when they should be repotted in small sixties and still kept under glass in heat for about 15 days, after which time they should be gradually exposed to a cooler temperature. Finally, plunge them in sand or ashes in a nearly cool frame, taking care to protect them well in severe weather. If the young plants have been repotted in good sandy peat-soil, kept free from all stagnant moisture, and not allowed to push before the ensuing spring, they will do well, and most of them will be fit for grafting in the following August. Cuttings struck in summer and autumn may also be used, but they are often liable to rot at the roots in consequence of the unfavourable winter weather which usually succeeds the operation. Be careful to leave some branches on the plants from which the cuttings are taken, otherwise they will be very likely to perish during the next winter.—D. GUIHENEUF.

**Cross-breeding.**—An interesting and probably a very important question with regard to this matter would be, whether the ovary fertilised by foreign pollen, and enclosing the seed is, when developed into a fruit, pod, capsule, burr, &c., to be considered as a first generation of hybrid fruit, or merely as a part of the mother-plant enveloping the hybrid seed, which will next year produce the first generation of hybrid fruit? Were the subject suited to a horticultural journal one might, arguing from analogy with what takes place in the animal kingdom, bring forward many arguments in favour of the first supposition. Every now and then instances are brought forward by able botanists showing that this influence of the foreign pollen is already visible on the envelope of the hybrid seed. I am of opinion that these instances would be more numerous were they habitually looked for, and were not the idea pretty general that the plantule contained in the seed is the only part of the fruit affected by crossing, the rest being only a part of the mother-plant. Of course, probably many hundred hybrid fruits would have to be duly examined before any notable or worthy variation could be found; but what a saving of time and expense it would be if the fact could be established that the sower need only sow the pips found in a notable or worthy variety on the mother-plant, discarding all others.—FREDK. PALMER, Versailles.

#### NOTES AND QUESTIONS ON PROPAGATING.

**New Plan for Double Working Pear Grafts.**—The following is an American plan for double working such varieties of Pears as are difficult to graft on the Quince. The reluctant variety, whatever it may be, is taken and grafted on some other Pear—the Bartlett for instance; the latter is then cut from the parent tree and grafted on the Quince. Growth in both scions follows at once, and at least a year's time is thus gained. This method is also said to improve the habits of some straggling varieties; the Seckle, for instance, double worked on the Bartlett, will grow much faster than when grafted directly on the Quince.

**Cold Grafting-Wax or Mastic.**—The following composition is recommended by M. Rodemakers, of Maeseyck.—Rosin, 12 oz.; hog's-lard, 2 oz.; alcohol of 30°, 27 oz. Melt the rosin and hog's-lard together over a gentle fire. Take the vessel off the fire and add the alcohol as speedily as possible, and in small portions at a time, taking care to keep the mixture well stirred while doing so. Then pour it into a tin box, which should be kept well closed until required for use.

**Manetti Rose Stocks.**—I have fifty Manetti stocks, varying from 4 to 5 feet in height, which is the proper way to bud them? Should they be cut down or left as they are, and be budded as standards?—ANNORS. [They should be cut down to about 18 inches, root and all; then planted; and at the budding season they should be worked just beneath the ground, and at the junction of the root and stem. This will necessitate taking away the soil carefully, so as not to injure the bark; for standards Manettis are useless.]

**Roses from Cuttings.**—I have a bed containing Finches of clean washed sand; the bottom is bored full of 2-inch holes, over which is spread straw, to prevent the sand from falling through. The pipe which conducts the hot water through my greenhouse is completely boxed up under the bed, which affords a strong bottom-heat, and I have sashes over the cuttings which confine the heat that arises from the sand. I keep the cuttings moist by watering with clear rain-water, at about 70° temperature. The glasses must be kept close, only occasionally raising them to give air, and thus circumstanced, Roses root freely.—T. H. H.

## THE KITCHEN GARDEN.

### HISTORY OF THE "ROSE" POTATOES.

BY DR. HEXAMER, NEWCASTLE, NEW YORK.

"THE Early Rose" was the pioneer of this remarkable race of Potatoes. It was originated by Mr. Bresse, of Brandon, who sold his then small stock to Mr. Heffron, of Utica. Up to this time it was known as "Chili Seedling," and was exhibited under that name at several shows in the fall of 1867. Shortly afterwards Mr. Heffron sold half of his stock to Mr. Conover, of New Jersey, and the other half to Mr. Bliss, of New York, at the same time changing the name to "Early Rose." The excitement which accompanied the introduction of this Potato is fresh in the memory of Potato growers. It soon became the leading early Potato, and is as yet not excelled by any newer kind. The "Late Rose," also known as "Thorburn's Late Rose," was introduced in the spring of 1872. This differs from most other named sorts in not being a seedling or original variety, but a sport or sub-variety. It was discovered by Mr. Coe, of Washington County, who, observing that a few Vines among his "Early Rose" remained fresh and green for several months longer than the others, caused these hills to be dug separately and planted in the following spring, when they retained the characteristics shown the previous year, and their offspring have continued to do so ever since. Samples of this Potato were exhibited for the first time in 1871, at the New York State Fair in Albany, where they attracted much attention. The Late Rose differs from the Early Rose in ripening later, being more prolific, and in keeping better; in quality and appearance they are nearly alike. "Bliss's Late Rose" is identical with this one. "Campbell's Late Rose" is a seedling raised by Mr. George Campbell, of Ohio. This variety seems to vary more than others, when grown in different soils and localities. With me, on a somewhat heavy clay soil, it proved exceedingly prolific, more so than any other variety in my experimental field, but in quality it fell much behind expectations. It is very late, the shoots have a vigorous straggling growth, remaining green until killed by frost. Some of the tubers grew very large, a few over 12 inches long, but more than one-half of the crop is too small for market; the medium and large ones are irregular, knotty and scraggy, and mostly hollow in the centre. In some localities, however, it has given better satisfaction. The whole appearance of the plant and tubers reminds one of the old Merino Potato. "Young's White Rose" introduced by Mr. Young, of Wisconsin, is a large, white, heavy Potato, resembling the Harrison so much that, during three years' trial, I could not discover any difference between the two. "Wainwright's White Rose" is a seedling by Mr. George Wainwright, of Pennsylvania. In shape and size it is something like the Orono, but its skin is rougher and not as white as that of the latter. It rotted badly the past season, and has not developed any desirable qualities. "Queen of the Roses" was raised by Mr. William Minnich, of Pennsylvania, from a seedball of the Early Rose. It is of exceedingly fine appearance, and, on the grounds of the originator, very prolific, but needs more extensive trials to determine its value. "The Whither Forest Rose" is a seedling or an old kind under a new name, I cannot tell which, but it looks exactly like the Monitor. The first sample came from Vermont. "Foster's Late Rose" is a seedling raised by Mr. Foster of Long Island, probably the first variety named "Late Rose." It was exhibited at the American Institute Fair in 1870, a year before any other "Late Rose" became known. The priority to the name would therefore belong to this variety, but, as it was never disseminated to any extent, the late variety of the Early Rose has now the right conceded to the name "Late Rose."

**Fluke Potatoes.**—Hearing a deal about the good quality of these, and their general freedom from disease, I was induced to make a trial of some. The first year, however, I only purchased a very small quantity. They were treated in every respect like other sets, but were so long in making their appearance above ground that I almost feared they would not come up at all, and many of them really did not grow. Those that did push gave a very fair yield, but nothing extraordinary; their quality was, however, very good. On finding this to be the case, nearly all were set aside to plant another year. They kept capitally, and with a quantity which I purchased were planted last spring, in the usual manner, with the exception of a little more manure; and, as in the preceding year, they came up badly, but greatly improved during the summer. On taking them up I was by no means disappointed, for both as regards number, size, and quality they were admirable. During the two years I have grown them they have been remarkably free from disease.—T.

GARDEN STRUCTURES.

GROUND VINERIES AND PLANT PRESERVERS.

OF these we give two illustrations, both the invention of Messrs. Boulton, of Norwich. The first, a ground Vinery, obtained the only prize medal awarded for such contrivances at the Royal Horticultural Society's Show at Birmingham, last year. The second, a plant preserver, has glass sides and ends, and in that respect, as well as in some others, is an improvement on the first; inasmuch as higher sides admit more light to the inmates, be they either plants or Vines, and its neat appearance permits its being placed in positions where more unsightly objects could not be allowed to stand, but yet where something of the kind is wanted. The uses to which such contrivances may be put are well known to most of us, the greatest perhaps being the enabling us to secure crops of fruit and vegetables five or six weeks earlier than where no such assistance is given, as well as preserving them in good condition later in the season than they could otherwise be had. Every convenience is provided to save time in cases of removal, planting, watering, and giving air. A neat arrangement has also been contrived for setting open the lights for purposes of ventilation, and for securing them from being blown up or down by wind in exposed situations. The glass is firmly fixed and puttied, an essential point, preventing, as it does, all escape of warmth from within; and a great advantage belonging to such frames is, they are complete and ready for use the moment they are received. Their price, too, is so inconsiderable as to bring them within the reach of everybody.

Boulton's Ground Vinery.

**Californian Flowering Plants and Shrubs.**—Among the more beautiful and fragrant flowers found in California, the Lily and

Boulton's Plant Preserver.

Syringa family are conspicuous; some of the latter forming large trees, which, when in bloom, are so completely enveloped with cone-like clusters as to suggest the presence of small white clouds resting on the verge of the horizon. These flowers, emitting the pleasant odour peculiar to their kind, fill the air for a long way around with the most delicious perfume; and although the wild flowers of California are so generally inodorous, the atmosphere, owing to their incredible numbers, and the fact that a few are highly fragrant, is fairly oppressed with the rich aroma thrown off by them in the spring and early summer.—*T. F. Cronise.*

PLANT ORIGIN OF COAL.

COAL, one of the most ancient remains of the primeval world, is acknowledged to be of vegetable origin, and to have been formed at a period anterior to the advent of man. Before Adam existed coal was formed. This useful mineralised vegetable production consists of four elementary bodies—carbon, hydrogen, oxygen, and nitrogen—and these produce nearly fifty other substances. In warm lakes or marshes reeds of different kinds spring up, and grow with amazing rapidity, and as readily decay, forming soil for other plants of similar habits, which in their turn die and in which the seeds of

forest trees readily take root, and accumulate around them undergrowths and sand and mud always to be found in coal-beds above the clay bottoms upon which the water and decayed vegetation rests. Prof. Phillips says:—"Under each coal seam a stratum of ancient soil exists, in which there are commonly found the roots of ancient trees, while above the coal there is a layer of sandstone or shale, in which are not unfrequently found the trunks of those trees—whose roots being in the mass of decayed vegetation below the shale are found either fallen or in their original position, and are only partly converted into coal." The atmosphere in the early coal formation teemed with the deadly carbonic gas, as well as with oxygen and nitrogen; so also does the atmosphere of the swamps of the Amazons to this day, but in a less degree. And this is favourable to the growth of the reeds and other

vegetation which delight to have their roots in the tepid water on the surface of the clay, that appears to be essential to the formation of coalbeds. Many generations of these plants lived and died, absorbing the water, their remains sinking deeper and deeper as time elapsed. By-and-by sand and earth drifted, or was conveyed by the wind and deposited upon the corrupting vegetation, which then became fit soil for trees that grew and flourished, their roots penetrating into the decayed undergrowths, and yet the earth encircled their trunks. Ferns, Calamites, and other similar growths sprang up, mingled also with reeds, and thus the undergrowth and decayed branches of the trees sunk down into

the mass, and again one or many succeeding layers of deposit went down, till as soon as the submergence of the mass under the water was complete the late trees which had formed a forest began to decay, and sunk prostrate upon the soft matter of embryo coal. Earthquakes or other earth disturbances may have toppled rocks or other earth upon the mass, or sandy or earth particles been drifted upon it, and thus in darkness and in heat generated by damp and pressure the coal formation commenced. Forest and other large trees have contributed but little to the material of coal deposit, the source of creation of the material has been from the decaying

refuse of various small plants, which never reached so far as even the branches of the trees. The fossil Floras of the coal formation in many different places are remarkably similar. In a number of specimens of coal obtained from various places trees are recognisable as having grown upon the vegetable deposit, but not as forming coal-beds, although they have in some instances been converted into coal, in others to a petrified structure of stone, in which the bark and the medullary rings of the trunk are preserved with all the characteristics peculiar to the species of trees. The various kinds of coal result from the different manner of formation and the different species of vegetation of which it is composed. Bituminous coal being the result of decayed Pine trees and others possessing similar gums, mingled with gigantic Club-Mosses, Ferns, Equisetums, Cypresses, Junipers, Arhorvitæ, and Calamites, grown in swamps, is undoubtedly the purest kind of coal. It kindles readily, and burns with a steady, cheerful flame, leaving a residue in cinder. Coal with wood-like texture, that burns to a white ash, originated in reeds, Alder and Hazel undergrowths, and plants without gum, long macerated in shallow waters and suddenly covered up. Coal produced from peat, Mosses, and Pine refuse long grown in swamps and sunk down without earth convulsions, but with little bitumen, is an excellent coal, though it will burn to a white ash. Where sand, stones, and shales occur in coal it shows that the vegetable matter had drifted by the combined action of wind and water, and the coal will be slaty and earthy, the lumps laminated and not easily broken. Anthracite contains but little bitumen, oxygen, or hydrogen. It is an ancient coal, from which heat and time have extracted them. Cannel, or candle coal, abounds in hydrogen, burns with a beautifully clear flame, and is the best coal for making gas.—*Warren Francis.*

### ROYAL BOTANIC GARDEN, EDINBURGH.

We learn from the curator's report for 1872 that several improvements have lately been made in this garden. A house for half-hardy trees has been erected, and when the heating has been provided for by the introduction of extra pipes, the plants now crowded in a cooler annexe of the Palm-house will be transferred to it. When this is accomplished, the unseemly partition in the Palm-house will be taken down, and the two buildings for Palms will be united into one. By this means room will be given for the Palms at present in cultivation. The new half-hardy house is about 40 feet high, 50 feet in breadth from north to south, and 60 feet from east to west; it is constructed of iron, and surmounted by a dome. It is hoped that next year the cool houses on each side will be incorporated with it by taking away the partitions, and thus full scope will be given for the exhibition and study of the plants. The improvement in the museum by the formation of the glass roof has enabled visitors to see the specimens properly, and has facilitated the arrangements for lectures and demonstrations. The rock garden has been much extended. In the formation of it the stones of some of the old walls have been utilised. It is hoped that, in the course of another year, this most useful and interesting part of the garden will be completed. The Edinburgh Botanical Society have handed over to the garden their entire library. The gift has been accepted by Government, and a room has been provided for the reception of the books. This library is open to fellows of the Botanical Society, and to any visitors who wish to study the plants in the garden and herbarium. The visitors to the garden during the year have amounted to 71,391.

## THE ARBORETUM.

### MOVEMENT OF THE SAP.

It may perhaps be usefully suggested, that in all attempts to trace out and define the movement of the sap, it should be borne in mind that though plants, like animals, must take in, digest, and assimilate food, because, like animals, they live and grow, yet that these functions, which in the latter are performed by motions, more or less complicated, of the muscular tissue, must, in the former, as inanimate beings, be performed passively, as far as the plant is concerned. If the plant's food—water, more or less charged with nutritive particles—be taken in at the spongiolæ, ascend and be conveyed through the plant up to the leaves, and thence, after having had its character changed, flow through and permeate the whole system; this can only be done by such natural forces as can of themselves cause these motions in fluids in general.

The only ones applicable are, capillary attraction, by which liquids will ascend in capillary tubes; gravitation, which tends to make liquids run down; the syphon, a complex one, which will make a liquid ascend, pass a bend, and fall again; and endosmose, which will cause two liquids of different natures to exchange places, through an organic diaphragm, without the help of any openings. That

there are two fluids in plants—the crude food as it comes from the earth, and the digested or true sap—cannot be doubted, as any one may ascertain for himself by tasting the real sap of the Sugar Maple, &c. It may, therefore, be reasonably surmised that there exists sufficient difference in the natures of these liquids to cause endosmose; and, indeed, it would otherwise be nearly impossible to account for the passage of the two saps in those numberless places where the continuity of capillary and other tubes ceases, and the way is blocked up by tissue. The four above-named forces could, therefore, draw in the liquid food at the roots, and convey it upwards, laterally, and downwards (as in the branches of the Weeping Willow), up to the very leaves, where, according to the received opinion—probably a very true, yet a mongrel sort of one, because it confounds food with venous blood—it is in these so-styled lungs of the plant changed into true sap; and the same forces could convey the true sap in its turn to every part of the organism. No external force can rationally be admitted to be the mover of the sap or saps, although heat is a great accelerator of them. This latter part it might perform, not only by evaporating part of the liquid from the leaves, thus making room for the new inflow, but also perhaps by directly expanding the liquid itself in the cavities of the plant. It never, however, could be the primary cause of motion in sap, which, although slackened during winter, so as to be sometimes scarcely perceptible, like the pulsations of hibernating animals during this season, yet exists nevertheless, as is proved by the evolution of roots during winter. The building up of cellular and fibrous tissue would probably come under those chemical laws or forces common to the mineral as well as to the animal kingdom and by which the atoms of a mineral solution will as unerringly build up a complicated crystal without omitting a single angle, as those of animal liquids will form bone, muscle, fat, &c.

*Versailles.*

FRED. PALMER.

### THE ARAUCARIA BIDWILLII AT KEW.

BY JOHN SMITH, EX-CURATOR.

THIS species of *Araucaria* (see p. 194) was first discovered by woodcutters, in a district of Moreton Bay (now Queensland), and a young plant of it was sent to Mr. Bidwill, then superintendent, *pro tem.*, of the Botanic Garden at Sydney. He sent the plant to this country, and it was offered for sale at Stevens', I think in 1812, the upset price being £25, but at that sum there were no bidders; consequently Mr. Stevens asked me if I would take the plant under my charge at Kew, which I did. It was then about 18 inches in height, and ultimately Mr. Bidwill made a present of it to the garden. At the time of its removal to the "Winter Garden," in 1862, it had attained a height of 12 feet, with a spread of branches of 18 feet, and a girth of stem near the base of 2 feet 6 inches. It was then a compact handsome plant, growing in a square box. Subsequently other plants of this *Araucaria* were received at Kew, one of which, when sent to the "Winter Garden," had attained a height of 10 feet, a spread of branches of as many feet, and a girth of stem of 1 foot 2 inches. In its native country, which lies between the 26th and 28th parallel of south latitude, it becomes a lofty tree, attaining a height of from 130 to even 170 feet, with a girth of 25 feet. The cones are of an oblong-conical form, 9 inches in length and 5 inches in diameter, or even larger; they contain more than one hundred nut-like seeds, the kernels of which are about the size of a Walnut, and form an important article of food to the natives, who, when the nuts are ripe, congregate in hundreds to feed upon them. They call them "Bunya-Bunya"; they have an Almond-like flavour, and those who eat them get fat upon them. This kind of food being of great importance to the natives, Government has issued orders that the trees are not to be cut down. Each tribe of natives has its own group of trees, and of these each family has a certain number, which is hereditary property, any trespass on which is vigorously resisted. Although Government, as I have said, has passed an Act to prevent the destruction of the trees, such forests being only ninety miles from Brisbane, and their wood being found useful for many purposes, it is feared that as the country becomes cultivated the Bunya-Bunya trees will get scarce, and that the natives, when taken up for stealing from the settlers, will say, "What can we do? you first destroyed our kangaroos, and now you have taken our Bunya-Bunya, and in time we ourselves will disappear from the land, and be replaced by civilised men."

**Exotic Trees and Shrubs in Devon.**—Will you kindly tell me the name of this *Acacia* from Australia? I believe it to be *A. heterophylla*, but I am not certain. It has grown out of doors in my shrubbery for many years, along with *Sikkin*, *Neigherry*, and *Nepaul Rhododendrons*, *Olea ilicifolia*, a species of *Eurybia*, *Ozo-*

thamnus rosmariifolias, Fagus antarctica (or Cunninghamii, I am not certain which), Cerasus ilicifolia, which makes a rambling straggling shrub, Dracena indivisa, the Huon Pine (Dacrydium Franklini), the Desfontainea spinosa and the Celery-topped Pine, from Mount Egmont, New Zealand, a kind with very marked peculiar foliage, something like that of Asplenium Trichomanes, and with very upright growth. The different varieties of Azalea indica do well in the same shrubbery, and Rhododendron fulgens and Hodgsonii are just showing flower, and will, I hope, be out in another fortnight; but though Rhododendron Wightii has grown for ten years it has not yet shown a single blossom, though very healthy in foliage.—THE COLONEL, *Tiverton, Devon*. [The specimen is too imperfect to name with certainty; kindly send us a piece when in flower, or when the leaves are more fully developed.]

## HARDY TREES AND SHRUBS.

BY GEORGE GORDON, A.L.S.

THE COLUMBIA MOCK ORANGE (PHILADELPHUS GORDONIANUS). This forms a many-stemmed vigorous-growing deciduous shrub, which attains a height of from 8 to 10 feet. Its prin-

The Columbia Mock Orange.

cipal stems are more or less ascending; the branchlets are slender and somewhat pendulous, and when a certain amount of size has been attained a number of strong shoots of a whitish colour are annually produced from the base. It is a native of the north-west coast of America, where it grows in the shape of underwood along the banks of the Columbia River. It is also found in Upper California, in shady woods along the Sacramento River. In this country it grows freely in any common garden soil, and it is readily increased either by seeds, which are ripe in October, or by means of cuttings of the half-ripened shoots in August. It was first introduced in 1826. The leaves (see p. 231), are somewhat small, ovate, pointed, coarsely toothed on the edges, three to five nerved, and produced on short footstalks; when in the adult state they are smooth and bright green above and hirsute beneath. The flowers are large, pure white, and scentless, and are produced in great profusion in terminal compact racemes, of from five to nine flowers each, in the end of July. The fruit or capsule, which is ripe in October, is comparatively large and semi-superior, with a large, broad, spreading calyx attached to it. This species of Mock Orange is one of the finest and most

showy of the genus, and it deserves a place in every collection of shrubs, however limited, on account of its producing its flowers in great profusion, and at a season when nearly all other shrubs have done blooming. It is sometimes misnamed *Philadelphus californicus*. The length of a full-sized leaf is 3 inches, including the footstalk, which is not more than half an inch long, and the breadth is 2 inches.

## WORK FOR THE WEEK.

### PRIVATE GARDENS.

**Flower Garden.**—Stir the soil occasionally amongst spring-blooming plants, and if slugs are troublesome scatter some air-slaked lime around the outsides of the beds in which they are growing. Edgings of *Stachys lanata*, *Cerastium*, variegated *Thyme*, *Gnaphalium lanatum*, variegated *Arabis*, variegated *Queen of the Meadow*, *Aucuba-leaved Daisies*, crimson-leaved *Ajuga*, the dwarf *Campanulas*, *Santolinas*, and a few other compact-growing plants, may now be lifted, divided, and transplanted. Two-year-old edgings are generally better than one, so that unless they exceed that age, they are better left undisturbed. The variegated *Polemonium carolinum* makes one of our finest hardy edgings; the best way of treating it is to lift the roots and pot them in October or November, to keep them during the winter in a frame or cool Peach-house, and to transplant them in spring when they begin to grow. Transplant from frames, greenhouses, or pits into beds in the flower garden, *Pinks* and *Carnations* wintered in pots, or autumn layers planted in light soil in frames in winter. Bulbs of *Lilies* yet in store should be planted as speedily as possible. *Pansies* and other spring blooming plants may yet be transplanted as occasion requires; indeed, few plants are more useful at any season than *Pansies*. *Gladioli* for blooming in beds or shrubbery borders may be planted at once 3 or 4 inches deep, and a sprinkling of sand should be strowed under and over the bulbs. It is a prevalent idea that *Gladioli* should not be transplanted till April for fear of spring frosts; but that is too late unless the plants are required for late flowering. Sow *Mignonette* where it is required to bloom, and hardy annuals not sown last September here and there in beds or borders for transplanting. Sow also a good stock of *Sweet Peas*, *Nasturtiums*, *Tropaeolums*, and *Scarlet Runners*, either where they are to bloom or in sheltered beds or corners for transplanting hereafter to their permanent quarters. Autumn-saved roots of *Scarlet Runners* throw up shoots freely, and bloom earlier than seedlings; the roots require treatment similar to that usually given to *Bahias*. Divide and transplant roots of herbaceous plants of various sorts.

**Lawns.**—If worm-casts are prevalent on these prepare some limo water, mixing therein some soot and salt, and water the lawn with the mixture through a rough rose; this not only gets rid of the worms but invigorates the Grass. Pieces of ground about to be converted into lawns should be turfed at once, or if turf cannot be obtained, they should be thickly sown down with Grass seeds. Hollows or other irregularities should be made level at once. In such operations the turf should be carefully skinned off and used again, for in no case should patches of new Grass be visible on permanent lawns; the more prominent portions of lawns will have been already mown this season, but now the whole of the Grass-surface should be cut. It should first be gone over with a wooden-toothed rake, and *Beech* nuts, small stones, and other things detrimental to the scythe or mowing machine should be removed by means of a daisy rake or a birch-broom. After that well roll the Grass previous to mowing. *Plantains*, *Dandelions*, *Daisies*, and similar plants the riddance of which from lawns is a desideratum, may now be eradicated. If Moss prevails amongst the Grass, rake the roughest of it off, and apply a dressing of sifted rich soil over the whole surface, which will so stimulate the Grass as to make it choke the Moss.

**Shrubberies.**—The transplanting of Evergreen trees and shrubs may yet be safely performed; indeed, vegetation is so backward this spring that even deciduous trees and shrubs may yet be safely removed. The pruning of the latter, as well as of Evergreens, should be finished at once, if not already done. Shrubby borders should be lightly pointed over, taking care not to injure the roots in the operation, or to disturb any bulbous plants that may be growing amongst the shrubs. Isolated specimens of newly planted trees, especially if large, are much benefited by a few shrubs being planted around them for a year or two to act as a protection from wind, frost, and drought; after they get established the nurses may be removed. Roses of all kinds should now be pruned, and those on pillars or walls thinned and fastened in. Prune, where necessary, *Ivies* on walls, and fasten any in danger of falling away from them. Uncover *Myrtles*, *Magnolias*, *Fremontias*, *Stantonias*,

Clematises, and other half-hardy plants on walls, and otherwise put them in order for the summer.

**Bedding Plants.**—From greenhouses and other plant and fruit houses it may now be necessary to remove Pelargoniums into frames, in which they will keep perfectly well until bedding-out time. By keeping them in warm quarters, however, better supplies of cuttings are obtained. Proceed with the propagation of different subjects from seeds, cuttings, or divisions, as speedily as possible; for the stronger the plants are before they are planted out the better will they flower. Prick off from the seed-pans into other pans or boxes Lobelias, Wigandias, Petunias, Golden Feverfew, French and African Marigolds, Amaranthus, Brachycome, &c. Sow some crimson-leaved Beet, for flower garden purposes, in a very gentle heat or close pit. Pot off cuttings of all sorts as they become rooted; and after they have yielded up their tops for cuttings they may be placed in a position a little cooler than the propagating pit, unless a further supply is required. Repot autumn propagated Pelargoniums, and place them in a close pit or frame for a time. Give them plenty of water, but do not allow them to be saturated so much as to generate damp. Prick into boxes of light soil, seedlings and leaf-cuttings of succulents, and keep them in a position near the glass. Put into frames six or eight inches in depth of light soil; pack it firmly and into it transplant the autumn cuttings of Verbenas, Ageratums, Lobelias, Calceolarias, Salvias, &c.; from such a position they transplant with excellent roots. Similar frames are also extremely useful for Dahlias, for the roots, after being divided, may be planted in them, six inches apart, or the roots may be started in a propagating pit or frame, and transplanted to these cold frames. Sweet Peas sown in pots and boxes should be removed to cold frames after they have germinated. Stocks, Asters, Marigolds, &c., may be sown in very gentle hot-beds, that are ventilated a little day and night, and shaded from sun, for after the plants have appeared they are extremely susceptible of damp. When large enough for being pricked out singly, prepare another frame in the same way for them, prick them thereon, shade well for a few days, and eventually completely expose them, but replace the sashes in showery weather or at night, when they may be tilted up. Instead of transplanting the Stocks and Asters in frames, a wall border with a south aspect will do equally well if a few sprigs of broom or Evergreen branches are stuck in front of them; indeed, seed of these plants may be sown out of doors in April with satisfactory results.

**Frames.**—Where bedding plants are largely grown these must be extensively used, but the frames are not of so much importance as the protecting material. In all cases the bottom should be dry, or at least incapable of retaining any considerable amount of moisture. The sides may be of turf, bricks, or wood, with rafters or transverse bars for the support of sashes, or for bearing up longitudinal spars or boards, to support mats, canvas, or other covering. Under all circumstances sashes are the best and most convenient, and these should be drip-proof, and cleanly washed. The material on which the plants stand inside may be sifted coal-ashes, clean gravel, or wood; or a hard bottom, such as a walk, may be covered with 6 or 8 inches of light mould, into which dwarf growing, fibrous-rooted plants may be transplanted six weeks or so prior to being bedded out, after which the soil may be cast out, and a layer of ashes placed in the bottom for the reception of Fuchsias, Cinerarias, and other greenhouse plants. Where frames are the only receptacles for bedding plants, the exclusion of frost is often indifferently effected, fire-heat when used being sometimes of a parching character next the pipes, and only moderate at the other extreme, and coverings necessitate a long period of darkness just when the plants are most liable to damp off, and the atmosphere least drying. An excellent means of obviating so much darkness and damping, and at the same time of preserving the plants in health, is practised by Mr. Cannell, of Woolwich, who, with two rows of 1 inch pipe, run along the inside of the rafters of narrow frames, and three rows in the case of wide frames, manages to have the whole interior atmosphere equally heated, and the greatest winter enemy of soft-wooded plants—damp, kept in abeyance. These pipes can easily be heated from any adjoining boiler, or by means of one purposely set for the frames, if the latter are extensive.

**Orchids.**—Last month and the present one constitute the recognised season for repotting Orchids; it is, however, almost impossible to adhere strictly to this rule, other departments requiring so much attention at this busy time of the year; Orchid-potting and overhauling are, therefore, for the most part, done in winter. For such as are quite dormant, winter potting is quite applicable, provided the plants are kept dry after the operation until required to start into growth. Lælias, Cattleyas, Angreecums, &c., also Oncidiums on blocks, and others, may be safely treated in this way; whereas terrestrial Orchids, such as Phajus, Miltonias, Calanthes, Sobralias, Bletias, &c., should be shifted just as they begin to grow. Now, when

all Orchids are in a growing state, a moist atmosphere and a gradually-increasing temperature should be maintained. Sprinkle water on the paths, walls, and stages, and keep a supply in the evaporating troughs. Syringe the plants daily, in time to permit the foliage to get dry before nightfall. Take care that plants on blocks are not hung up immediately over pot-plants, as the drip from them injures the leaves of the latter. See to the eradication of insects, such as green-fly, thrips, scale, &c., by fumigating or washing with water in which some soft soap and Gishurst's compound have been mixed. Let traps for cockroaches, in the form of jam-dishes with some treacle and water in them, be set amongst the plants, so that, when these pests fall into them, they may get drowned. Phosphorus paste also kills them. Ants may be trapped by means of sponges steeped in sugar and water, or in other sweet substances, placed here and there amongst the pots. Ants congregate on them in thousands, when they may be destroyed by plunging the sponge into boiling water. After the water cools, wring out the sponges, resteeep them in the sweet matter, and place them again amongst the pots. Fresh

Shoot of *Philadelphus Gordonianus*, showing the true shape of the leaves.  
(See page 233.)

bones, especially if hollow, form excellent traps for ants, which should be thrown into boiling water every morning, as in the case of the sponges. Trap wire-worms with cut Potatoes, and woodlice by means of little pots containing dry moss.

**Hardy Fruit Trees.**—Pruning and planting should now be completed, and any training yet undone should also be finished. Espaliers requiring new stakes should have them supplied at once. Any trees loosened from walls for the purpose of "pointing" the latter *i.e.*, filling up holes between the bricks caused by repeated nailing, should be fastened to them again, for the buds are now swelling fast. Fruit trees, however, are not nearly so forward as it was anticipated some two months ago they would be. If not already done, however, no time should now be lost in affording protection to Apricots, Peaches, and Plums on walls. If Strawberry plantations require increasing they should now receive attention. Old plantations of them, if not already done, should be mulched, which will both feed the plants and keep the fruit clean.

## THE GARDEN.

"This is an art  
Which does mend nature: change it rather: but  
THE ART ITSELF IS NATURE."—*Shakespeare.*

### THE TWEEDSIDE VINEYARD.

FROM Carlisle to Clovenford, which is near Galashiels, one seems travelling along a channel furrowed through a petrified sea. At some points the rounded hills advance on either side, as if about to embrace each other across the line. At others they recede to greater distances, opening up vistas, valleys, or streams, or revealing a far-reaching panorama of rolling hills, rising one above another until lost in the rain-clouds, or the debateable land of misty shadows that seem ever to hover over, or enshroud them as with a blue mantle. Hardly a sound is heard beyond that of some mountain stream here and there rushing down its rocky bed. And so we travel on and on, through moorland clothed with brown heath and shaggy woods, or through green hills, until we catch glimpses of the classic waters of the Ettrick, the Yarrow, and the Tweed. And then suddenly the last rays of the setting sun are thrown back in one's face, like a shower of diamonds, from a series of huge glass houses, placed in a niche at the base of the hills. "That," exclaimed a fellow traveller, "is Mr. Thomson's great vineyard."

The site of this vineyard, though seemingly too exposed, is admirable. It is sheltered on all sides, the wind being shut out by surrounding hills. The natural soil—the washings for generations from the hill sides, is an admirable rich, mellow loam, capable of growing Pines and Vines in perfection in its natural state. The vineyard is within a stone's throw of the Clovenford station, which links it to all the great markets in the country. Coal is cheap in Mr. Thomson's locality, and water is inexhaustible, and carries itself to where it is wanted. Any amount, indeed, of pure water can be run over the Vine borders by simply turning a tap and moving a hose. This represents a saving of labour that can hardly be over-estimated. The chief expenses, in fact, are in labour and fuel, and both are economised to the utmost. By building the vineyard in a block of three houses, each 200 feet long, connected at the end by means of a cross-house, that forms, as it were, an entrance hall or corridor to the others, each shelters and to some extent warms the rest. The ventilation is so perfect that either side or roof can be opened from end to end by a few turns of a crank. The heating is managed on the best principles, the amount of oxygen admitted to the furnaces being regulated to a nicety, so as to control combustion in such a manner as to get a maximum of heat from a minimum of fuel; time-saving expedients, too, are numerous. Quick growth is no longer held as synonymous with weakness. On the contrary, in Pine and Grape growing, especially, the faster the growth the stronger, heavier, and richer the produce. Skill must, however, keep abreast of speed, and when that is properly applied, it is astonishing how soon plants can be grown into produce—money. For instance, Pine-apples are now ripened in from twelve to fifteen months from rootless suckers. Old stems are forced to produce marshalled hosts of fine plants; small plants are made to bulk out into sturdy fruiting ones. Instead of the old system of disrooting and checking growth, Pines have now no rest until they ripen fruit. A few plants now and then may refuse to "show" at the right moment, and in that case they are simply cut over at the neck, and brought to earth afresh. This radical treatment never fails to send the fruit quickly up, and, properly treated, such plants ripen their fruit well. It is seldom, however, that such measures are needed. The strength of the plants from the first seems concentrated in their necks. Broad, sturdy leaves and stems throw up and finish off perfect fruit.

As another illustration of speedy culture, I would advert to the Duke of Buccleuch Grape. When at the vineyard last September, I hardly think that Mr. Thomson had a single plant of this kind in pots, for he had planted two houses with it, which had pretty well absorbed his stock. Yet now he seems to have plenty of it. The fact is, every eye is converted into a plant. Neither is time thus gained by an extra amount
